Multiplies the low int32 elements from each packed 64-bit element in *a* and *b*, and stores the signed 64-bit result.

_mm512_mask_mul_epi32

```
extern __m512i __cdecl _mm512_mask_mul_epi32(__m512i src, __mmask8 k, __m512i a, __m512i b);
```

Multiplies the low int32 elements from each packed 64-bit element in *a* and *b*, and stores the signed 64-bit result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_mul_epi32

```
extern __m512i __cdecl _mm512_maskz_mul_epi32(__mmask8 k, __m512i a, __m512i b);
```

Multiplies the low int32 elements from each packed 64-bit element in *a* and *b*, and stores the signed 64-bit result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mullo_epi32

```
extern __m512i __cdecl _mm512_mullo_epi32(__m512i a, __m512i b);
```

Multiplies the packed int32 elements in *a* and *b*, producing intermediate int64 elements, and stores the low 32 bits of the intermediate integers.

_mm512_mask_mullo_epi32

```
extern __m512i __cdecl _mm512_mask_mullo_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b);
```

Multiplies the packed int32 elements in *a* and *b*, producing intermediate int64 elements, and stores the low 32 bits of the intermediate integers in destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_mul_epu32

```
extern __m512i __cdecl _mm512_mul_epu32(__m512i a, __m512i b);
```

Multiplies the low unsigned int32 elements from each packed 64-bit element in *a* and *b*, and stores the unsigned 64-bit result.

_mm512_mask_mul_epu32

```
extern __m512i __cdecl _mm512_mask_mul_epu32(__m512i src, __mmask8 k, __m512i a, __m512i b);
```

Multiplies the low unsigned int32 elements from each packed 64-bit element in *a* and *b*, and stores the unsigned 64-bit result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_mul_epu32

```
extern __m512i __cdecl _mm512_maskz_mul_epu32(__mmask8 k, __m512i a, __m512i b);
```

Multiplies the low unsigned int32 elements from each packed 64-bit element in *a* and *b*, and stores the unsigned 64-bit result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mullox_epi64

```
extern __m512i __cdecl _mm512_mullox_epi64(__m512i a, __m512i b);
```

Multiplies each packed int64 element in *a* and *b*, and selects the low bits of each product.

_mm512_mask_mullox_epi64

```
extern __m512i __cdecl _mm512_mask_mullox_epi64(__m512i, __mmask8 k, __m512i a, __m512i b);
```

Multiplies each packed int64 element in *a* and *b*, and selects the low bits of each product, using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Subtraction Operations

Intrinsics for FP Subtraction Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_sub_pd`, `_mm512_mask_sub_pd`, `_mm512_maskz_sub_pd` `_mm512_sub_round_pd`, `_mm512_mask_sub_round_pd`, `_mm512_maskz_sub_round_pd`	Subtracts float64 vectors.	`VSUBPD`

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_sub_ps`, `_mm512_mask_sub_ps`, `_mm512_maskz_sub_ps` `_mm512_sub_round_ps`, `_mm512_mask_sub_round_ps`, `_mm512_maskz_sub_round_ps`	Subtracts float32 vectors.	`VSUBPS`
`_mm_mask_sub_sd`, `_mm_maskz_sub_sd` `_mm_sub_round_sd`, `_mm_mask_sub_round_sd`, `_mm_maskz_sub_round_sd`	Subtracts float64 vectors.	`VSUBSD`
`_mm_mask_sub_ss`, `_mm_maskz_sub_ss` `_mm_sub_round_ss`, `_mm_mask_sub_round_ss`, `_mm_maskz_sub_round_ss`	Subtracts float32 vectors.	`VSUBSS`

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result
round	Rounding control values; these can be one of the following (along with the `sae` suppress all exceptions flag): • `_MM_FROUND_TO_NEAREST_INT` - rounds to nearest even • `_MM_FROUND_TO_NEG_INF` - rounds to negative infinity • `_MM_FROUND_TO_POS_INF` - rounds to positive infinity • `_MM_FROUND_TO_ZERO` - rounds to zero • `_MM_FROUND_CUR_DIRECTION` - rounds using default from MXCSR register

_mm512_sub_pd

```
extern __m512d __cdecl _mm512_sub_pd(__m512d a, __m512d b);
```

Subtracts packed float64 elements in vector *b* from vector *a*, and stores the result.

_mm512_mask_sub_pd

```
extern __m512d __cdecl _mm512_mask_sub_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
```

Subtracts packed float64 elements in *b* from packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_sub_pd

```
extern __m512d __cdecl _mm512_maskz_sub_pd(__mmask8 k, __m512d a, __m512d b);
```

Subtracts packed float64 elements in *b* from packed float64 elements in *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_sub_round_pd

```
extern __m512d __cdecl _mm512_sub_round_pd(__m512d a, __m512d b, int round);
```

Subtracts packed float64 elements in *b* from packed float64 elements in *a*using rounding control *round*, and stores the result.

_mm512_mask_sub_round_pd

```
extern __m512d __cdecl _mm512_mask_sub_round_pd(__m512d src, __mmask8 k, __m512d a, __m512d b,
int round);
```

Subtracts packed float64 elements in *b* from packed float64 elements in *a* using rounding control *round*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_sub_round_pd

```
extern __m512d __cdecl _mm512_maskz_sub_round_pd(__mmask8 k, __m512d a, __m512d b, int round);
```

Subtracts packed float64 elements in *b* from packed float64 elements in *a* using rounding control *round*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_sub_ps

```
extern __m512 __cdecl _mm512_sub_ps(__m512 a, __m512 b);
```

Subtracts packed float32 elements in *b* from packed float32 elements in *a*, and stores the result.

_mm512_mask_sub_ps

```
extern __m512 __cdecl _mm512_mask_sub_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);
```

Subtracts packed float32 elements in *b* from packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_sub_ps

```
extern __m512 __cdecl _mm512_maskz_sub_ps(__mmask16 k, __m512 a, __m512 b);
```

Subtracts packed float32 elements in *b* from packed float32 elements in *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_sub_round_ps

```
extern __m512 __cdecl _mm512_sub_round_ps(__m512 a, __m512 b, int round);
```

Subtracts packed float32 elements in *b* from packed float32 elements in *a*, and stores the result.

_mm512_mask_sub_round_ps

```
extern __m512 __cdecl _mm512_mask_sub_round_ps(__m512 src, __mmask16 k, __m512 a, __m512 b, int
round);
```

Subtracts packed float32 elements in *b* from packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_sub_round_ps

```
extern __m512 __cdecl _mm512_maskz_sub_round_ps(__mmask16 k, __m512 a, __m512 b, int round);
```

Subtracts packed float32 elements in *b* from packed float32 elements in *a* using rounding control *round*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_sub_sd

```
extern __m128d __cdecl _mm_mask_sub_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
```

Subtracts the lower float64 element in *b* from the lower float64 element in *a*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper element from *a* to the upper destination element.

_mm_maskz_sub_sd

```
extern __m128d __cdecl _mm_maskz_sub_sd(__mmask8 k, __m128d a, __m128d b);
```

Subtracts the lower float64 element in *b* from the lower float64 element in *a*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper element from *a* to the upper destination element.

_mm_sub_round_sd

```
extern __m128d __cdecl _mm_sub_round_sd(__m128d a, __m128d b, int round);
```

Subtracts the lower float64 element in *b* from the lower float64 element in *a*, stores the result in the lower destination element, and copies the upper element from *a* to the upper destination element.

_mm_mask_sub_round_sd

```
extern __m128d __cdecl _mm_mask_sub_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b, int
round);
```

Subtracts the lower float64 element in *b* from the lower float64 element in *a* using rounding control *round*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper element from *a* to the upper destination element.

_mm_maskz_sub_round_sd

```
extern __m128d __cdecl _mm_maskz_sub_round_sd(__mmask8 k, __m128d a, __m128d b, int round);
```

Subtracts the lower float64 element in *b* from the lower float64 element in *a*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper element from *a* to the upper destination element.

_mm_sub_round_ss

```
extern __m128 __cdecl _mm_sub_round_ss(__m128 a, __m128 b, int round);
```

Subtracts the lower float32 element in *b* from the lower float32 element in *a*, stores the result in the lower destination element, and copies the upper three packed elements from *a* to the upper destination elements.

_mm_mask_sub_round_ss

```
extern __m128 __cdecl _mm_mask_sub_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b, int
round);
```

Subtracts the lower float32 element in *b* from the lower float32 element in *a*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper three packed elements from *a* to the upper destination elements.

_mm_maskz_sub_round_ss

```
extern __m128 __cdecl _mm_maskz_sub_round_ss(__mmask8 k, __m128 a, __m128 b, int round);
```

Subtracts the lower float32 element in *b* from the lower float32 element in *a*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from *a* to the upper destination elements.

_mm_mask_sub_ss

```
extern __m128 __cdecl _mm_mask_sub_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);
```

Subtracts the lower float32 element in *b* from the lower float32 element in *a*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper three packed elements from *a* to the upper destination elements.

_mm_maskz_sub_ss

```
extern __m128 __cdecl _mm_maskz_sub_ss(__mmask8 k, __m128 a, __m128 b);
```

Subtracts the lower float32 element in *b* from the lower float32 element in *a*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from *a* to the upper destination elements.

_mm_sub_round_ss

```
extern __m128 __cdecl _mm_sub_round_ss(__m128 a, __m128 b, int round);
```

Subtracts the lower float32 element in *b* from the lower float32 element in *a*, stores the result in the lower destination element, and copy the upper three packed elements from *a* to the upper destination elements.

_mm_mask_sub_round_ss

```
extern __m128 __cdecl _mm_mask_sub_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b, int
round);
```

Subtract the lower float32 element in *b* from the lower float32 element in *a*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper three packed elements from *a* to the upper destination elements.

_mm_maskz_sub_round_ss

```
extern __m128 __cdecl _mm_maskz_sub_round_ss(__mmask8 k, __m128 a, __m128 b, int round);
```

Subtracts the lower float32 element in *b* from the lower float32 element in *a*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from *a* to the upper destination elements.

Intrinsics for Integer Subtraction Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_sub_epi32`, `_mm512_maskz_sub_epi32`	Subtracts int32 elements.	`VPSUBD`
`_mm512_sub_epi64`, `_mm512_mask_sub_epi64`, `_mm512_maskz_sub_epi64`	Subtracts int64 elements.	`VPSUBQ`

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result

_mm512_sub_epi32

```
extern __m512i __cdecl _mm512_sub_epi32(__m512i a, __m512i b);
```

Subtracts packed 32-bit integers in *b* from packed 32-bit integers in *a*, and stores the result.

_mm512_maskz_sub_epi32

```
extern __m512i __cdecl _mm512_maskz_sub_epi32(__mmask16 k, __m512i a, __m512i b);
```

Subtracts packed 32-bit integers in *b* from packed 32-bit integers in *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_sub_epi64

```
extern __m512i __cdecl _mm512_sub_epi64(__m512i a, __m512i b);
```

Subtracts packed 64-bit integers in *b* from packed 64-bit integers in *a*, and stores the result.

_mm512_mask_sub_epi64

```
extern __m512i __cdecl _mm512_mask_sub_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
```

Subtracts packed 64-bit integers in *b* from packed 64-bit integers in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_sub_epi64

```
extern __m512i __cdecl _mm512_maskz_sub_epi64(__mmask8 k, __m512i a, __m512i b);
```

Subtracts packed 64-bit integers in *b* from packed 64-bit integers in *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Other Mathematics Operations

Intrinsics for FP Division Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_div_round_pd, _mm512_mask_div_round_pd, _mm512_maskz_div_round_pd	Calculates quotient of a rounded division operation of packed float64 elements.	VDIVPD
_mm512_div_pd, _mm512_mask_div_pd, _mm512_maskz_div_pd		
_mm512_div_round_ps, _mm512_mask_div_round_ps, _mm512_maskz_div_round_ps	Calculates quotient of a rounded division operation of packed float32 elements.	VDIVPS

_mm_div_round_ss, _mm_mask_div_round_ss, _mm_maskz_div_round_ss	Calculates quotient of a rounded division operation of scalar float32 elements.	VDIVSS
_mm_mask_div_ss, _mm_maskz_div_ss		

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element

variable	definition
src	source element to use based on writemask result
round	Rounding control values; these can be one of the following (along with the `sae` suppress all exceptions flag): • `_MM_FROUND_TO_NEAREST_INT` - rounds to nearest even • `_MM_FROUND_TO_NEG_INF` - rounds to negative infinity • `_MM_FROUND_TO_POS_INF` - rounds to positive infinity • `_MM_FROUND_TO_ZERO` - rounds to zero • `_MM_FROUND_CUR_DIRECTION` - rounds using default from MXCSR register

_mm512_div_pd

```
extern __m512d __cdecl _mm512_div_pd(__m512d a, __m512d b);
```

Divides packed float64 elements in *a* by packed elements in *b*, and stores the result.

_mm512_mask_div_pd

```
extern __m512d __cdecl _mm512_mask_div_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
```

Divides packed float64 elements in *a* by packed elements in *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_div_pd

```
extern __m512d __cdecl _mm512_maskz_div_pd(__mmask8 k, __m512d a, __m512d b);
```

Divides packed float64 elements in *a* by packed elements in *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_div_round_pd

```
extern __m512d __cdecl _mm512_div_round_pd(__m512d a, __m512d b, int round);
```

Divides packed float64 elements in *a* by packed elements in *b*, and stores the result.

_mm512_mask_div_round_pd

```
extern __m512d __cdecl _mm512_mask_div_round_pd(__m512d src, __mmask8 k, __m512d a, __m512d b,
int round);
```

Divides packed float64 elements in *a* by packed elements in *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_div_round_pd

```
extern __m512d __cdecl _mm512_maskz_div_round_pd(__mmask8 k, __m512d a, __m512d b, int round);
```

Divides packed float64 elements in *a* by packed elements in *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_div_ps

```
extern __m512 __cdecl _mm512_div_ps(__m512 a, __m512 b);
```

Divides packed float32 elements in *a* by packed elements in *b*, and stores the result.

_mm512_mask_div_ps

```
extern __m512 __cdecl _mm512_mask_div_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);
```

Divides packed float32 elements in *a* by packed elements in *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_div_ps

```
extern __m512 __cdecl _mm512_maskz_div__ps(__mmask16 k, __m512 a, __m512 b);
```

Divides packed float32 elements in *a* by packed elements in *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_div_round_ps

```
extern __m512 __cdecl _mm512_div_round_ps(__m512 a, __m512 b, int round);
```

Divides packed float32 elements in *a* by packed elements in *b*, and stores the result.

_mm512_mask_div_round_ps

```
extern __m512 __cdecl _mm512_mask_div_round_ps(__m512 src, __mmask16 k, __m512 a, __m512 b, int
round);
```

Divides packed float32 elements in *a* by packed elements in *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_div_round_ps

```
extern __m512 __cdecl _mm512_maskz_div_round_ps(__mmask16 k, __m512 a, __m512 b, int round);
```

Divides packed float32 elements in *a* by packed elements in *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_div_sd

```
extern __m128d __cdecl _mm_mask_div_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
```

Divides the lower float64 element in *a* by the lower float64 element in *b*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper element from *a* to the upper destination element.

_mm_maskz_div_sd

```
extern __m128d __cdecl _mm_maskz_div_sd(__mmask8 k, __m128d a, __m128d b);
```

Divides the lower float64 element in *a* by the lower float64 element in *b*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper element from *a* to the upper destination element.

_mm_div_round_sd

```
extern __m128d __cdecl _mm_div_round_sd(__m128d a, __m128d b, int round);
```

Divides the lower float64 element in *a* by the lower float64 element in *b*, stores the result in the lower destination element, and copies the upper element from *a* to the upper destination element.

_mm_mask_div_round_sd

```
extern __m128d __cdecl _mm_maskz_div_round_sd(__mmask8 src, __m128d k, __m128d a, int round);
```

Divides the lower float64 element in *a* by the lower float64 element in *b*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper element from *a* to the upper destination element.

_mm_maskz_div_round_sd

```
extern __m128d __cdecl _mm_mask_div_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
```

Divides the lower float64 element in *a* by the lower float64 element in *b*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper element from *a* to the upper destination element.

_mm_div_round_ss

```
extern __m128 __cdecl _mm_div_round_ss(__m128 a, __m128 b, int round);
```

Divides the lower float32 element in *a* by the lower float32 element in *b*, stores the result in the lower destination element, and copies the upper three packed elements from *a* to the upper destination elements.

_mm_mask_div_round_ss

```
extern __m128 __cdecl _mm_mask_div_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b, int
round);
```

Divides the lower float32 element in *a* by the lower float32 element in *b*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper three packed elements from *a* to the upper destination elements.

_mm_maskz_div_round_ss

```
extern __m128 __cdecl _mm_maskz_div_round_ss(__mmask8 k, __m128 a, __m128 b, int round);
```

Divides the lower float32 element in *a* by the lower float32 element in *b*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from *a* to the upper destination elements.

_mm_mask_div_ss

```
extern __m128 __cdecl _mm_mask_div_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);
```

Divides the lower float32 element in *a* by the lower float32 element in *b*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper three packed elements from *a* to the upper destination elements.

_mm_maskz_div_ss

```
extern __m128 __cdecl _mm_maskz_div_ss(__mmask8 k, __m128 a, __m128 b);
```

Divides the lower float32 element in *a* by the lower float32 element in *b*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from *a* to the upper destination elements.

Intrinsics for Absolute Value Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_abs_epi32`, `_mm512_mask_abs_epi32`, `_mm512_maskz_abs_epi32`	Computes absolute value of int32 vector elements.	`VPABSD`
`_mm512_abs_epi64`, `_mm512_mask_abs_epi64`, `_mm512_maskz_abs_epi64`	Computes absolute value of int64 vector elements.	`VPABSQ`

variable	definition
k	writemask used as a selector
a	first source vector element
src	source element to use based on writemask result

_mm512_abs_epi32

```
extern __m512i __cdecl _mm512_abs_epi32(__m512i a);
```

Computes absolute value of packed int32 elements in *a*, and stores unsigned results in destination.

_mm512_mask_abs_epi32

```
extern __m512i __cdecl _mm512_mask_abs_epi32(__m512i src, __mmask16 k, __m512i a);
```

Computes absolute value of packed int32 elements in *a*, and stores unsigned results in destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_abs_epi32

```
extern __m512i __cdecl _mm512_maskz_abs_epi32(__mmask16 k, __m512i a);
```

Computes absolute value of packed int32 elements in *a*, and stores unsigned results in destination using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_abs_epi64

```
extern __m512i __cdecl _mm512_abs_epi64(__m512i a);
```

Computes absolute value of packed int64 elements in *a*, and stores unsigned results in destination.

_mm512_mask_abs_epi64

```
extern __m512i __cdecl _mm512_mask_abs_epi64(__m512i src, __mmask8 k, __m512i a);
```

Computes absolute value of packed int64 elements in *a*, and stores unsigned results in destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_abs_epi64

```
extern __m512i __cdecl _mm512_maskz_abs_epi64(__mmask8 k, __m512i a);
```

Computes absolute value of packed int64 elements in *a*, and stores unsigned results in destination using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Scale Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result
round	Rounding control values; these can be one of the following (along with the `sae` suppress all exceptions flag): • `_MM_FROUND_TO_NEAREST_INT` - rounds to nearest even • `_MM_FROUND_TO_NEG_INF` - rounds to negative infinity • `_MM_FROUND_TO_POS_INF` - rounds to positive infinity • `_MM_FROUND_TO_ZERO` - rounds to zero • `_MM_FROUND_CUR_DIRECTION` - rounds using default from MXCSR register
imm	8-bit immediate integer specifies offset for destination

_mm512_roundscale_pd

```
extern __m512d __cdecl _mm512_roundscale_pd(__m512d a, int imm);
```

Performs a floating point scale of packed float64 elements in *a* to the number of fraction bits specified by *imm*, and stores the result.

_mm512_mask_roundscale_pd

```
extern __m512d __cdecl _mm512_mask_roundscale_pd(__m512d src, __mmask8 k, __m512d a, int imm);
```

Performs a floating point scale of packed float64 elements in *a* to the number of fraction bits specified by *imm*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_roundscale_pd

```
extern __m512d __cdecl _mm512_maskz_roundscale_pd(__mmask8 k, __m512d a, int imm);
```

Performs a floating point scale of packed float64 elements in *a* to the number of fraction bits specified by *imm*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_roundscale_ps

```
extern __m512 __cdecl _mm512_roundscale_ps(__m512 a, int imm);
```

Performs a floating point scale of packed float32 elements in *a* to the number of fraction bits specified by *imm*, and stores the result.

_mm512_mask_roundscale_ps

```
extern __m512 __cdecl _mm512_mask_roundscale_ps(__m512 src, __mmask16 k, __m512 a, int imm);
```

Performs a floating point scale of packed float32 elements in *a* to the number of fraction bits specified by *imm*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_roundscale_ps

```
extern __m512 __cdecl _mm512_maskz_roundscale_ps(__mmask16 k, __m512 a, int imm);
```

Performs a floating point scale of packed float32 elements in *a* to the number of fraction bits specified by *imm*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm_roundscale_round_sd

```
extern __m128d __cdecl _mm_roundscale_round_sd(__m128d a, __m128d b, const int imm, const int
round);
```

Rounds the lower float64 element in *a* to the number of fraction bits specified by *imm*, stores the result in the lower destination element, and copies the upper element from *b* to the upper destination element.

_mm_mask_roundscale_round_sd

```
extern __m128d __cdecl _mm_mask_roundscale_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d
b, const int imm, const int round);
```

Rounds the lower float64 element in *a* to the number of fraction bits specified by *imm*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper element from *b* to the upper destination element.

_mm_maskz_roundscale_round_sd

```
extern __m128d __cdecl _mm_maskz_roundscale_round_sd(__mmask8 k, __m128d a, __m128d b, const int
imm, const int round);
```

Rounds the lower float64 element in *a* to the number of fraction bits specified by *imm*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper element from *b* to the upper destination element.

_mm_roundscale_sd

```
extern __m128d __cdecl _mm_roundscale_sd(__m128d a, __m128d b, const int imm);
```

Rounds the lower float64 element in *a* to the number of fraction bits specified by *imm*, stores the result in the lower destination element, and copies the upper element from *b* to the upper destination element.

_mm_mask_roundscale_sd

```
extern __m128d __cdecl _mm_mask_roundscale_sd(__m128d old, __mmask8 k, __m128d a, __m128d b,
const int imm);
```

Rounds the lower float64 element in *a* to the number of fraction bits specified by *imm*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper element from *b* to the upper destination element.

_mm_maskz_roundscale_sd

```
extern __m128d __cdecl _mm_maskz_roundscale_sd(__mmask8 k, __m128d a, __m128d b, const int imm);
```

Rounds the lower float64 element in *a* to the number of fraction bits specified by *imm*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper element from *b* to the upper destination element.

_mm_roundscale_round_ss

```
extern __m128 __cdecl _mm_roundscale_round_ss(__m128 a, __m128 b, const int imm, const int
round);
```

Rounds the lower float32 element in *a* to the number of fraction bits specified by *imm*, stores the result in the lower destination element, and copies the upper three packed elements from *b* to the upper destination elements.

_mm_mask_roundscale_round_ss

```
extern __m128 __cdecl _mm_mask_roundscale_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b,
const int imm, const int round);
```

Rounds the lower float32 element in *a* to the number of fraction bits specified by *imm*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper three packed elements from *b* to the upper destination elements.

_mm_maskz_roundscale_round_ss

```
extern __m128 __cdecl _mm_maskz_roundscale_round_ss(__mmask8 k, __m128 a, __m128 b, const int
imm, const int round);
```

Rounds the lower float32 element in *a* to the number of fraction bits specified by *imm*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from *b* to the upper destination elements.

_mm_roundscale_ss

```
extern __m128 __cdecl _mm_roundscale_ss(__m128 a, __m128 b, const int imm);
```

Rounds the lower float32 element in *a* to the number of fraction bits specified by *imm*, stores the result in the lower destination element, and copies the upper three packed elements from *b* to the upper destination elements.

_mm_mask_roundscale_ss

```
extern __m128 __cdecl _mm_mask_roundscale_ss(__m128 src, __mmask8 k, __m128 a, __m128 b, const
int imm);
```

Rounds the lower float32 element in *a* to the number of fraction bits specified by *imm*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper three packed elements from *b* to the upper destination elements.

_mm_maskz_roundscale_ss

```
extern __m128 __cdecl _mm_maskz_roundscale_ss(__mmask8 k, __m128 a, __m128 b, const int imm);
```

Rounds the lower float32 element in *a* to the number of fraction bits specified by *imm*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from *b* to the upper destination elements.

_mm512_scalef_pd

```
extern __m512d __cdecl  _mm512_scalef_pd(__m512d a, __m512d b);
```

Performs a floating point scale of the packed float64 elements in source *a* by multiplying by 2^b, and stores the result.

_mm512_mask_scalef_pd

```
extern __m512d __cdecl _mm512_mask_scalef_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
```

Performs a floating point scale of the packed float64 elements in source *a* by multiplying by 2^b, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_scalef_pd

```
extern __m512d __cdecl _mm512_maskz_scalef_pd(__mmask8 k, __m512d a, __m512d b);
```

Performs a floating point scale of the packed float64 elements in source *a* by multiplying by 2^b, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_scalef_round_pd

```
extern __m512d __cdecl _mm512_scalef_round_pd(__m512d a, __m512d b, int round);
```

Performs a floating point scale of the rounded packed float64 elements in source *a* by multiplying by 2^b, and stores the result.

_mm512_mask_scalef_round_pd

```
extern __m512d __cdecl _mm512_mask_scalef_round_pd(__m512d src, __mmask8 k, __m512d a, __m512d
b, int round);
```

Performs a floating point scale of the rounded packed float64 elements in source *a* by multiplying by 2^b, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_scalef_round_pd

```
extern __m512d __cdecl _mm512_maskz_scalef_round_pd(__mmask8 k, __m512d a, __m512d b, int round);
```

Performs a floating point scale of the rounded packed float64 elements in source *a* by multiplying by 2^b, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_scalef_ps

```
extern __m512 __cdecl _mm512_scalef_ps(__m512 a, __m512 b);
```

Performs a floating point scale of the packed float32 elements in source *a* by multiplying by 2^b, and stores the result.

_mm512_mask_scalef_ps

```
extern __m512 __cdecl _mm512_mask_scalef_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);
```

Performs a floating point scale of the packed float32 elements in source *a* by multiplying by 2^b, and stores the result, using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_scalef_ps

```
extern __m512 __cdecl _mm512_maskz_scalef_ps(__mmask16 k, __m512 a, __m512 b);
```

Performs a floating point scale of the packed single-precision (64-bit) floating-point elements in source *a* by multiplying by 2^b, and stores the result, using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_scalef_round_ps

```
extern __m512 __cdecl _mm512_scalef_round_ps(__m512 a, __m512 b, int round);
```

Performs a floating point scale of the rounded packed single-precision (64-bit) floating-point elements in source *a* by multiplying by 2^b, and stores the results.

_mm512_mask_scalef_round_ps

```
extern __m512 __cdecl _mm512_mask_scalef_round_ps(__m512 src, __mmask16 k, __m512 a, __m512 b,
int round);
```

Performs a floating point scale of the rounded packed single-precision (64-bit) floating-point elements in source *a* by multiplying by 2^b, and stores the results, using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_scalef_round_ps

```
extern __m512 __cdecl _mm512_maskz_scalef_round_ps(__mmask16 k, __m512 a, __m512 b, int round);
```

Performs a floating point scale of the rounded packed single-precision (64-bit) floating-point elements in source *a* by multiplying by 2^b, and stores the results, using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm_scalef_round_sd

```
extern __m128d __cdecl _mm_scalef_round_sd(__m128d a, __m128d b, int round);
```

Performs a floating point scale of the rounded scalar float64 elements in source *a* by multiplying by 2^b, stores the result in the lower destination element, and copies the upper element from *b* to the upper destination element.

_mm_mask_scalef_round_sd

```
extern __m128d __cdecl _mm_mask_scalef_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b,
int round);
```

Performs a floating point scale of the rounded scalar float64 elements in source *a* by multiplying by 2^b, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper element from *b* to the upper destination element.

_mm_maskz_scalef_round_sd

```
extern __m128d __cdecl _mm_maskz_scalef_round_sd(__mmask8 k, __m128d a, __m128d b, int round);
```

Performs a floating point scale of the rounded scalar float64 elements in source *a* by multiplying by 2^b, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper element from *b* to the upper destination element.

_mm_scalef_sd

```
extern __m128d __cdecl _mm_scalef_sd(__m128d a, __m128d b);
```

Performs a floating point scale of the scalar float64 elements in source *a* using values from *b*, stores the result in the lower destination element, and copies the upper element from *b* to the upper destination element.

_mm_mask_scalef_sd

```
extern __m128d __cdecl _mm_mask_scalef_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
```

Performs a floating point scale of the scalar float64 elements in source *a* using values from *b*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper element from *b* to the upper destination element.

_mm_maskz_scalef_sd

```
extern __m128d __cdecl _mm_maskz_scalef_sd(__mmask8 k, __m128d a, __m128d b);
```

Performs a floating point scale of the scalar float64 elements in source *a* using values from *b*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper element from *b* to the upper destination element.

_mm_scalef_round_ss

```
extern __m128 __cdecl _mm_scalef_round_ss(__m128 a, __m128 b, int  round);
```

Performs a floating point scale of the rounded scalar float32 elements in source *a* by multiplying by 2^b, stores the result in the lower destination element, and copies the upper element from *b* to the upper destination elements.

_mm_mask_scalef_round_ss

```
extern __m128 __cdecl _mm_mask_scalef_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b, int
round);
```

Performs a floating point scale of the rounded scalar float32 elements in source *a* by multiplying by 2^b, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper three packed elements from *b* to the upper destination elements.

_mm_maskz_scalef_round_ss

```
extern __m128 __cdecl _mm_maskz_scalef_round_ss(__mmask8 k, __m128 a, __m128 b, int  round);
```

Performs a floating point scale of the rounded scalar float32 elements in source *a* by multiplying by 2^b, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from *b* to the upper destination elements.

_mm_scalef_ss

```
extern __m128 __cdecl _mm_scalef_ss(__m128 a, __m128 b);
```

Performs a floating point scale of the scalar float32 elements in source *a* using values from *b*, stores the result in the lower destination element, and copies the upper three packed elements from *b* to the upper destination elements.

_mm_mask_scalef_ss

```
extern __m128 __cdecl _mm_mask_scalef_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);
```

Performs a floating point scale of the scalar float32 elements in source *a* using values from *b*, stores the result in the lower destination element, using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper three packed elements from *b* to the upper destination elements.

_mm_maskz_scalef_ss

```
extern __m128 __cdecl _mm_maskz_scalef_ss(__mmask8 k, __m128 a, __m128 b);
```

Performs a floating point scale of the scalar float32 elements in source *a* using values from *b*, stores the result in the lower destination element, using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from *b* to the upper destination elements.

Intrinsics for Blend Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

NOTE
The opmask register is not used as a writemask for these instructions. Instead, the mask is used as an element selector: every element of the destination is conditionally selected between first source or second source using the value of the related mask bit ('0' for the first source operand, '1' for the second source operand), the elements with corresponding mask bit value of '0' in the destination operand are zeroed.

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_mask_blend_pd`	Blend float64 vector elements using instruction mask.	`VBLENDMPD`
`_mm512_mask_blend_ps`	Blend float32 vector elements using instruction mask.	`VBLENDMPS`
`_mm512_mask_blend_epi32`	Blend int32 vectors using instruction mask.	`VPBLENDMD`
`_mm512_mask_blend_epi64`	Blend int64 vectors using instruction mask.	`VPBLENDMQ`

variable	definition
k	instruction mask used as a selector
a	first source vector element
b	second source vector element

_mm512_mask_blend_pd

```
extern m512d __cdecl _mm512_mask_blend_pd(__mmask8 k, __m512d a, __m512d b);
```

Performs element-by-element blending of float64 source vectors *a* and *b*, using the instruction mask *k* as selector.

The result is written into float64 vector destination register.

_mm512_mask_blend_ps

```
extern m512 __cdecl _mm512_mask_blend_ps(__mmask16 k, __m512 a, __m512 b);
```

Performs element-by-element blending of float32 source vectors *a* and *b*, using the instruction mask *k* as selector.

The result is written into an float32 vector register.

_mm512_mask_blend_epi32

```
extern m512i __cdecl _mm512_mask_blend_epi32(__mmask16 k, __m512i a, __m512i b);
```

Performs element-by-element blending of int32 source vectors *a* and *b*, using the instruction mask *k* as selector.

The result is written into an int32 vector register.

_mm512_mask_blend_epi64

```
extern m512i __cdecl _mm512_mask_blend_epi64(__mmask8 k, __m512i a, __m512i b);
```

Performs element-by-element blending of int64 source vectors *a* and *b*, using the instruction mask *k* as selector.

The result is written into an int64 vector register.

Intrinsics for Bit Manipulation Operations

Intrinsics for Integer Bit Manipulation and Conflict Detection Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_lzcnt_epi32`, `_mm512_mask_lzcnt_epi32`, `_mm512_maskz_lzcnt_epi32`	Counts the leading zero bits in source int32 elements.	`VPLZCNTD`
`_mm512_lzcnt_epi64`, `_mm512_mask_lzcnt_epi64`, `_mm512_maskz_lzcnt_epi64`	Counts the leading zero bits in source int64 elements.	`VPLZCNTQ`
`_mm512_ternarylogic_epi32`, `_mm512_mask_ternarylogic_epi32`, `_mm512_maskz_ternarylogic_epi32`	Implements three-operand binary function specified by immediate value.	`VPTERNLOGD`
`_mm512_ternarylogic_epi64`, `_mm512_mask_ternarylogic_epi64`, `_mm512_maskz_ternarylogic_epi64`	Implements three-operand binary function specified by immediate value.	`VPTERNLOGQ`

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
c	third source vector element
imm8	binary function specifier
src	source element to use based on writemask result

_mm512_lzcnt_epi32

```
extern __m512i __cdecl _mm512_lzcnt_epi32(__m512i a);
```

Counts the number of leading zero bits in each packed 32-bit integer in *a*, and store the results in destination.

_mm512_mask_lzcnt_epi32

```
extern __m512i __cdecl _mm512_mask_lzcnt_epi32(__m512i src, __mmask16 k, __m512i a);
```

Counts the number of leading zero bits in each packed 32-bit integer in *a*, and store the results in destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_lzcnt_epi32

```
extern __m512i __cdecl _mm512_maskz_lzcnt_epi32(__mmask16 k, __m512i a);
```

Counts the number of leading zero bits in each packed 32-bit integer in *a*, and store the results in destination using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_lzcnt_epi64

```
extern __m512i __cdecl _mm512_lzcnt_epi64(__m512i a);
```

Counts the number of leading zero bits in each packed 64-bit integer in *a*, and store the results.

_mm512_mask_lzcnt_epi64

```
extern __m512i __cdecl _mm512_mask_lzcnt_epi64(__m512i src, __mmask8 k, __m512i a);
```

Counts the number of leading zero bits in each packed 64-bit integer in *a*, and store the results in using writemask *k*.

Elements are copied from *src* when the corresponding mask bit is not set.

_mm512_maskz_lzcnt_epi64

```
extern __m512i __cdecl _mm512_maskz_lzcnt_epi64(__mmask8 k, __m512i a);
```

Counts the number of leading zero bits in each packed 64-bit integer in *a*, and store the results in destination using zeromask *k*.

Elements are zeroed out when the corresponding mask bit is not set.

_mm512_ternarylogic_epi32

```
extern __m512i __cdecl _mm512_ternarylogic_epi32(__m512i a, __m512i b, __m512i c, int imm8);
```

Bitwise ternary logic to implement three-operand binary functions; the specific binary function is specified by value in *imm8*.

For each bit in each packed 32-bit integer, the corresponding bit from *a*, *b*, and *c* are used to form a 3 bit index into *imm8*, and the value at that bit in *imm8* is written to the corresponding destination bit.

_mm512_mask_ternarylogic_epi32

```
extern __m512i __cdecl _mm512_mask_ternarylogic_epi32(__m512i a, __mmask16 k, __m512i, __m512i
b, int imm8);
```

Bitwise ternary logic to implement three-operand binary functions; the specific binary function is specified by value in *imm8*.

For each bit in each packed 32-bit integer, the corresponding bit from *src*, *a*, and *b* are used to form a 3 bit index into *imm8*, and the value at that bit in *imm8* is written to the corresponding destination bit using writemask *k* at 32-bit granularity (32-bit elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_ternarylogic_epi32

```
extern __m512i __cdecl _mm512_maskz_ternarylogic_epi32(__mmask16 k, __m512i a, __m512i b,
__m512i c, int imm8);
```

Bitwise ternary logic to implement three-operand binary functions; the specific binary function is specified by value in *imm8*.

For each bit in each packed 32-bit integer, the corresponding bit from *a*, *b*, and *c* are used to form a 3 bit index into *imm8*, and the value at that bit in *imm8* is written to the corresponding destination bit using zeromask *k* at 32-bit granularity (32-bit elements are zeroed out when the corresponding mask bit is not set).

_mm512_ternarylogic_epi64

```
extern __m512i __cdecl _mm512_ternarylogic_epi64(__m512i a, __m512i b, __m512i c, int imm8);
```

Bitwise ternary logic to implement three-operand binary functions; the specific binary function is specified by value in *imm8*.

For each bit in each packed 64-bit integer, the corresponding bit from *a*, *b*, and *c* are used to form a 3-bit index into *imm8*, and the value at that bit in *imm8* is written to the corresponding destination bit.

_mm512_mask_ternarylogic_epi64

```
extern __m512i __cdecl _mm512_mask_ternarylogic_epi64(__m512i src, __mmask8 k, __m512i a,
__m512i b, int imm8);
```

Bitwise ternary logic to implement three-operand binary functions; the specific binary function is specified by value in *imm8*.

For each bit in each packed 64-bit integer, the corresponding bit from *src*, *a*, and *b* are used to form a 3 bit index into *imm8*, and the value at that bit in *imm8* is written to the corresponding destination bit using writemask *k* at 64-bit granularity (64-bit elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_ternarylogic_epi64

```
extern __m512i __cdecl _mm512_maskz_ternarylogic_epi64(__mmask8 k, __m512i a, __m512i b, __m512i
c, int imm8);
```

Bitwise ternary logic to implement three-operand binary functions; the specific binary function is specified by value in *imm8*.

For each bit in each packed 64-bit integer, the corresponding bit from *a*, *b*, and *c* are used to form a 3 bit index into *imm8*, and the value at that bit in *imm8* is written to the corresponding destination bit using zeromask *k* at 64-bit granularity (64-bit elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Bitwise Logical Operations

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result

_mm512_and_epi32

```
extern __m512i __cdecl _mm512_and_epi32(__m512i a, __m512i b);
```

Computes the bitwise AND of packed 32-bit integers in *a* and *b*, and stores the result.

_mm512_mask_and_epi32

```
extern __m512i __cdecl _mm512_mask_and_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b);
```

Computes the bitwise AND of packed 32-bit integers in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_maskz_and_epi32

```
extern __m512i __cdecl _mm512_maskz_and_epi32(__mmask16 k, __m512i a, __m512i b);
```

Computes the bitwise AND of packed 32-bit integers in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_and_epi64

```
extern __m512i __cdecl _mm512_and_epi64(__m512i a, __m512i b);
```

Computes the bitwise AND of 512 bits (composed of packed 64-bit integers) in *a* and *b*, and stores the result.

_mm512_mask_and_epi64

```
extern __m512i __cdecl _mm512_mask_and_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
```

Computes the bitwise AND of packed 64-bit integers in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_and_epi64

```
extern __m512i __cdecl _mm512_maskz_and_epi64(__mmask8 k, __m512i a, __m512i b);
```

Computes the bitwise AND of packed 64-bit integers in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_andnot_epi32

```
extern __m512i __cdecl _mm512_andnot_epi32(__m512i a, __m512i b);
```

Computes the bitwise AND NOT of packed 32-bit integers in *a* and *b*, and stores the result.

_mm512_mask_andnot_epi32

```
extern __m512i __cdecl _mm512_mask_andnot_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b);
```

Computes the bitwise AND NOT of packed 32-bit integers in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_andnot_epi32

```
extern __m512i __cdecl _mm512_maskz_andnot_epi32(__mmask16 k, __m512i a, __m512i b);
```

Computes the bitwise AND NOT of packed 32-bit integers in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_andnot_epi64

```
extern __m512i __cdecl _mm512_andnot_epi64(__m512i a, __m512i b);
```

Computes the bitwise AND NOT of 512 bits (composed of packed 64-bit integers) in *a* and *b*, and stores the result.

_mm512_mask_andnot_epi64

```
extern __m512i __cdecl _mm512_mask_andnot_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
```

Computes the bitwise AND NOT of packed 64-bit integers in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_andnot_epi64

```
extern __m512i __cdecl _mm512_maskz_andnot_epi64(__mmask8 k, __m512i a, __m512i b);
```

Computes the bitwise `AND NOT` of packed 64-bit integers in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_or_epi32

```
extern __m512i __cdecl _mm512_or_epi32(__m512i a, __m512i b);
```

Computes the bitwise `OR` of packed 32-bit integers in *a* and *b*, and stores the result.

_mm512_mask_or_epi32

```
extern __m512i __cdecl _mm512_mask_or_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b);
```

Computes the bitwise `OR` of packed 32-bit integers in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_or_epi32

```
extern __m512i __cdecl _mm512_maskz_or_epi32( __mmask16 k, __m512i a, __m512i b);
```

Computes the bitwise `OR` of packed 32-bit integers in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_or_epi64

```
extern __m512i __cdecl _mm512_or_epi64(__m512i a, __m512i b);
```

Computes the bitwise `OR` of packed 64-bit integers in *a* and *b*, and store the result.

_mm512_mask_or_epi64

```
extern __m512i __cdecl _mm512_mask_or_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
```

Computes the bitwise `OR` of packed 64-bit integers in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_or_epi64

```
extern __m512i __cdecl _mm512_maskz_or_epi64(__mmask8 k, __m512i a, __m512i b);
```

Computes the bitwise `OR` of packed 64-bit integers in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_xor_epi32

```
extern __m512i __cdecl _mm512_xor_epi32(__m512i a, __m512i b);
```

Computes the bitwise `XOR` of packed 32-bit integers in *a* and *b*, and stores the result.

_mm512_mask_xor_epi32

```
extern __m512i __cdecl _mm512_mask_xor_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b);
```

Computes the bitwise `XOR` of packed 32-bit integers in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_xor_epi32

```
extern __m512i __cdecl _mm512_maskz_xor_epi32(__mmask16 k, __m512i a, __m512i b);
```

Computes the bitwise XOR of packed 32-bit integers in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_xor_epi64

```
extern __m512i __cdecl _mm512_xor_epi64(__m512i a, __m512i b);
```

Computes the bitwise XOR of packed 64-bit integers in *a* and *b*, and stores the result.

_mm512_mask_xor_epi64

```
extern __m512i __cdecl _mm512_mask_xor_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
```

Computes the bitwise XOR of packed 64-bit integers in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_xor_epi64

```
extern __m512i __cdecl _mm512_maskz_xor_epi64(__mmask8 k, __m512i a, __m512i b);
```

Computes the bitwise XOR of packed 64-bit integers in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Integer Bit Rotation Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_rol_epi32, _mm512_mask_rol_epi32, _mm512_maskz_rol_epi32	Rotates bits of int32 source elements left by specified count.	VPROLD

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_rorv_epi32`, `_mm512_mask_rorv_epi32`, `_mm512_maskz_rorv_epi32`	Rotates bits of int32 source elements right by specified count.	`VPRORVD`
`_mm512_rorv_epi64`, `_mm512_mask_rorv_epi64`, `_mm512_maskz_rorv_epi64`	Rotates bits of int64 source elements right by specified count.	`VPRORVQ`

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result
imm	8-bit immediate integer specifies offset for destination

_mm512_rol_epi32

```
extern __m512i __cdecl _mm512_rol_epi32(__m512i a, const int imm);
```

Rotates bits in each packed int32 element in *a* to the left by the number of bits specified in *imm*, and stores the results.

_mm512_mask_rol_epi32

```
extern __m512i __cdecl _mm512_mask_rol_epi32(__m512i src, __mmask16 k, __m512i a, const int imm);
```

Rotates bits in each packed int32 element in *a* to the left by the number of bits specified in *imm*, and stores the results using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_rol_epi32

```
extern __m512i __cdecl _mm512_maskz_rol_epi32(__mmask16 k, __m512i a, const int imm);
```

Rotates bits in each packed int32 element in *a* to the left by the number of bits specified in *imm*, and stores the results using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_rol_epi64

```
extern __m512i __cdecl _mm512_rol_epi64(__m512i a, const int imm);
```

Rotates bits in each packed int64 element in *a* to the left by the number of bits specified in *imm*, and stores the results.

_mm512_mask_rol_epi64

```
extern __m512i __cdecl _mm512_mask_rol_epi64(__m512i src, __mmask8 k, __m512i a, const int imm);
```

Rotates bits in each packed int64 element in *a* to the left by the number of bits specified in *imm*, and stores the results using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_rol_epi64

```
extern __m512i __cdecl _mm512_maskz_rol_epi64(__mmask8 k, __m512i a, const int imm);
```

Rotates bits in each packed int64 element in *a* to the left by the number of bits specified in *imm*, and stores the results using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_rolv_epi32

```
extern __m512i __cdecl _mm512_rolv_epi32(__m512i a, __m512i b);
```

Rotates bits in each packed int32 element in *a* to the left by the number of bits specified in the corresponding element of *b*, and stores the results.

_mm512_mask_rolv_epi32

```
extern __m512i __cdecl _mm512_mask_rolv_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b);
```

Rotates bits in each packed int32 element in *a* to the left by the number of bits specified in the corresponding element of *b*, and stores the results using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_rolv_epi32

```
extern __m512i __cdecl _mm512_maskz_rolv_epi32(__mmask16 k, __m512i a, __m512i b);
```

Rotates bits in each packed int32 element in *a* to the left by the number of bits specified in the corresponding element of *b*, and stores the results using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_rolv_epi64

```
extern __m512i __cdecl _mm512_rolv_epi64(__m512i a, __m512i b);
```

Rotates bits in each packed int64 element in *a* to the left by the number of bits specified in the corresponding element of *b*, and stores the results.

_mm512_mask_rolv_epi64

```
extern __m512i __cdecl _mm512_mask_rolv_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
```

Rotates bits in each packed int64 element in *a* to the left by the number of bits specified in the corresponding element of *b*, and stores the results using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_rolv_epi64

```
extern __m512i __cdecl _mm512_maskz_rolv_epi64(__mmask8 k, __m512i a, __m512i b);
```

Rotates bits in each packed int64 element in *a* to the left by the number of bits specified in the corresponding element of *b*, and stores the results using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_ror_epi32

```
extern __m512i __cdecl _mm512_ror_epi32(__m512i a, int imm);
```

Rotates bits in each packed int32 element in *a* to the right by the number of bits specified in *imm*, and stores the results.

_mm512_mask_ror_epi32

```
extern __m512i __cdecl _mm512_mask_ror_epi32(__m512i src, __mmask16 k, __m512i a, int imm);
```

Rotates bits in each packed int32 element in *a* to the right by the number of bits specified in *imm*, and stores the results using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_ror_epi32

```
extern __m512i __cdecl _mm512_maskz_ror_epi32(__mmask16 k, __m512i a, int imm);
```

Rotates bits in each packed int32 element in *a* to the right by the number of bits specified in *imm*, and stores the results using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_ror_epi64

```
extern __m512i __cdecl _mm512_ror_epi64(__m512i a, int imm);
```

Rotates bits in each packed int64 element in *a* to the right by the number of bits specified in *imm*, and stores the results.

_mm512_mask_ror_epi64

```
extern __m512i __cdecl _mm512_mask_ror_epi64(__m512i src, __mmask8 k, __m512i a, int imm);
```

Rotates bits in each packed int64 element in *a* to the right by the number of bits specified in *imm*, and stores the results using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_ror_epi64

```
extern __m512i __cdecl _mm512_maskz_ror_epi64(__mmask8 k, __m512i a, int imm);
```

Rotates bits in each packed int64 element in *a* to the right by the number of bits specified in *imm*, and stores the results using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_rorv_epi32

```
extern __m512i __cdecl _mm512_rorv_epi32(__m512i a, __m512i b);
```

Rotates bits in each packed int32 element in *a* to the right by the number of bits specified in the corresponding element of *b*, and stores the results.

_mm512_mask_rorv_epi32

```
extern __m512i __cdecl _mm512_mask_rorv_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b);
```

Rotates bits in each packed int32 element in *a* to the right by the number of bits specified in the corresponding element of *b*, and stores the results using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_rorv_epi32

```
extern __m512i __cdecl _mm512_maskz_rorv_epi32(__mmask16 k, __m512i a, __m512i b);
```

Rotates bits in each packed int32 element in *a* to the right by the number of bits specified in the corresponding element of *b*, and stores the results using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_rorv_epi64

```
extern __m512i __cdecl _mm512_rorv_epi64(__m512i a, __m512i b);
```

Rotates bits in each packed int64 element in *a* to the right by the number of bits specified in the corresponding element of *b*, and stores the results.

_mm512_mask_rorv_epi64

```
extern __m512i __cdecl _mm512_mask_rorv_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
```

Rotates bits in each packed int64 element in *a* to the right by the number of bits specified in the corresponding element of *b*, and stores the results using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_rorv_epi64

```
extern __m512i __cdecl _mm512_maskz_rorv_epi64(__mmask8 k, __m512i a, __m512i b);
```

Rotates bits in each packed int64 element in *a* to the right by the number of bits specified in the corresponding element of *b*, and stores the results using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Integer Bit Shift Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_sll_epi32`, `_mm512_mask_sll_epi32`, `_mm512_maskz_sll_epi32` `_mm512_slli_epi32`, `_mm512_mask_slli_epi32`, `_mm512_maskz_slli_epi32`	Logical left shift of int32 elements.	`VPSLLD`
`_mm512_srl_epi32`, `_mm512_mask_srl_epi32`, `_mm512_maskz_srl_epi32` `_mm512_srli_epi32`, `_mm512_mask_srli_epi32`, `_mm512_maskz_srli_epi32`	Logical right shift of int32 elements.	`VPSRLD`
`_mm512_sll_epi64`, `_mm512_mask_sll_epi64`, `_mm512_maskz_sll_epi64` `_mm512_slli_epi64`, `_mm512_mask_slli_epi64`, `_mm512_maskz_slli_epi64`	Logical left shift of int64 elements.	`VPSLLQ`
`_mm512_srl_epi64`, `_mm512_mask_srl_epi64`, `_mm512_maskz_srl_epi64`	Logical right shift of int64 elements.	`VPSRLQ`

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_srli_epi64, _mm512_mask_srli_epi64, _mm512_maskz_srli_epi64

_mm512_srai_epi64, _mm512_mask_srai_epi64, _mm512_maskz_srai_epi64		

variable	definition
k	writemask used as a selector
a	first source vector element
src	source element to use based on writemask result
count	specifies the number of bits for shift operation

variable	definition
imm	8-bit immediate integer specifies offset for destination

_mm512_sll_epi32

```
extern __m512i __cdecl _mm512_sll_epi32(__m512i a, __m128i count);
```

Shifts packed int32 elements in *a* left by *count* while shifting in zeros, and stores the result.

_mm512_mask_sll_epi32

```
extern __m512i __cdecl _mm512_mask_sll_epi32(__m512i src, __mmask16 k, __m512i a, __m128i count);
```

Shifts packed int32 elements in *a* left by *count* while shifting in zeros, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_sll_epi32

```
extern __m512i __cdecl _mm512_maskz_sll_epi32(__mmask16 k, __m512i a, __m128i count);
```

Shifts packed int32 elements in *a* left by *count* while shifting in zeros, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_slli_epi32

```
extern __m512i __cdecl _mm512_slli_epi32(__m512i a, unsigned int imm);
```

Shifts packed int32 elements in *a* left by *imm* while shifting in zeros, and stores the result.

_mm512_mask_slli_epi32

```
extern __m512i __cdecl _mm512_mask_slli_epi32(__m512i src, __mmask16 k, __m512i a, unsigned int
imm);
```

Shifts packed int32 elements in *a* left by *imm* while shifting in zeros, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_slli_epi32

```
extern __m512i __cdecl _mm512_maskz_slli_epi32(__mmask16 k, __m512i a, unsigned int imm);
```

Shifts packed int32 elements in *a* left by *imm* while shifting in zeros, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_sll_epi64

```
extern __m512i __cdecl _mm512_sll_epi64(__m512i a, __m128i count);
```

Shifts packed int64 elements in *a* left by *count* while shifting in zeros, and stores the result.

_mm512_mask_sll_epi64

```
extern __m512i __cdecl _mm512_mask_sll_epi64(__m512i src, __mmask8 k, __m512i a, __m128i count);
```

Shifts packed int64 elements in *a* left by *count* while shifting in zeros, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_sll_epi64

```
extern __m512i __cdecl _mm512_maskz_sll_epi64(__mmask8 k, __m512i a, __m128i count);
```

Shifts packed int64 elements in *a* left by *count* while shifting in zeros, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_slli_epi64

```
extern __m512i __cdecl _mm512_slli_epi64(__m512i a, unsigned int imm);
```

Shifts packed int64 elements in *a* left by *imm* while shifting in zeros, and stores the result.

_mm512_mask_slli_epi64

```
extern __m512i __cdecl _mm512_mask_slli_epi64(__m512i src, __mmask8 k, __m512i a, unsigned int
imm);
```

Shifts packed int64 elements in *a* left by *imm* while shifting in zeros, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_slli_epi64

```
extern __m512i __cdecl _mm512_maskz_slli_epi64(__mmask8 k, __m512i a, unsigned int imm);
```

Shifts packed int64 elements in *a* left by *imm* while shifting in zeros, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_sllv_epi32

```
extern __m512i __cdecl _mm512_sllv_epi32(__m512i a, __m512i count);
```

Shifts packed int32 elements in *a* left by the amount specified by the corresponding element in *count* while shifting in zeros, and stores the result.

_mm512_mask_sllv_epi32

```
extern __m512i __cdecl _mm512_mask_sllv_epi32(__m512i src, __mmask16 k, __m512i a, __m512i
count);
```

Shifts packed int32 elements in *a* left by the amount specified by the corresponding element in *count* while shifting in zeros, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_sllv_epi32

```
extern __m512i __cdecl _mm512_maskz_sllv_epi32(__mmask16 k, __m512i a, __m512i count);
```

Shifts packed int32 elements in *a* left by the amount specified by the corresponding element in *count* while shifting in zeros, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_sllv_epi64

```
extern __m512i __cdecl _mm512_sllv_epi64(__m512i a, __m512i count);
```

Shifts packed int64 elements in *a* left by the amount specified by the corresponding element in *count* while shifting in zeros, and stores the result.

_mm512_mask_sllv_epi64

```
extern __m512i __cdecl _mm512_mask_sllv_epi64(__m512i src, __mmask8 k, __m512i a, __m512i count);
```

Shifts packed int64 elements in *a* left by the amount specified by the corresponding element in *count* while shifting in zeros, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_sllv_epi64

```
extern __m512i __cdecl _mm512_maskz_sllv_epi64(__mmask8 k, __m512i a, __m512i count);
```

Shifts packed int64 elements in *a* left by the amount specified by the corresponding element in *count* while shifting in zeros, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_sra_epi32

```
extern __m512i __cdecl _mm512_sra_epi32(__m512i a, __m128i count);
```

Shifts packed int32 elements in *a* right by *count* while shifting in sign bits, and stores the result.

_mm512_mask_sra_epi32

```
extern __m512i __cdecl _mm512_mask_sra_epi32(__m512i src, __mmask16 k, __m512i a, __m128i count);
```

Shifts packed int32 elements in *a* right by *count* while shifting in sign bits, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_sra_epi32

```
extern __m512i __cdecl _mm512_maskz_sra_epi32(__mmask16 k, __m512i a, __m128i count);
```

Shifts packed int32 elements in *a* right by *count* while shifting in sign bits, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_sra_epi64

```
extern __m512i __cdecl _mm512_sra_epi64(__m512i a, __m128i count);
```

Shifts packed int64 elements in *a* right by *count* while shifting in sign bits, and stores the result.

_mm512_mask_sra_epi64

```
extern __m512i __cdecl _mm512_mask_sra_epi64(__m512i src, __mmask8 k, __m512i a, __m128i count);
```

Shifts packed int64 elements in *a* right by *count* while shifting in sign bits, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_sra_epi64

```
extern __m512i __cdecl _mm512_maskz_sra_epi64(__mmask8 k, __m512i a, __m128i count);
```

Shifts packed int64 elements in *a* right by *count* while shifting in sign bits, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srai_epi32

```
extern __m512i __cdecl _mm512_srai_epi32(__m512i a, unsigned int imm);
```

Shifts packed int32 elements in *a* right by *imm* while shifting in sign bits, and stores the result.

_mm512_mask_srai_epi32

```
extern __m512i __cdecl _mm512_mask_srai_epi32(__m512i src, __mmask16 k, __m512i a, unsigned int
imm);
```

Shifts packed int32 elements in *a* right by *imm* while shifting in sign bits, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_srai_epi32

```
extern __m512i __cdecl _mm512_maskz_srai_epi32(__mmask16 k, __m512i a, unsigned int imm);
```

Shifts packed int32 elements in *a* right by *imm* while shifting in sign bits, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srai_epi64

```
extern __m512i __cdecl _mm512_srai_epi64(__m512i a, unsigned int imm);
```

Shifts packed int64 elements in *a* right by *imm* while shifting in sign bits, and stores the result.

_mm512_mask_srai_epi64

```
extern __m512i __cdecl _mm512_mask_srai_epi64(__m512i src, __mmask8 k, __m512i a, unsigned int
imm);
```

Shifts packed int64 elements in *a* right by *imm* while shifting in sign bits, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_srai_epi64

```
extern __m512i __cdecl _mm512_maskz_srai_epi64(__mmask8 k, __m512i a, unsigned int imm);
```

Shifts packed int64 elements in *a* right by *imm* while shifting in sign bits, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srav_epi32

```
extern __m512i __cdecl _mm512_srav_epi32(__m512i a, __m512i count);
```

Shifts packed int32 elements in *a* right by the amount specified by the corresponding element in *count* while shifting in sign bits, and stores the result.

_mm512_mask_srav_epi32

```
extern __m512i __cdecl _mm512_mask_srav_epi32(__m512i src, __mmask16 k, __m512i a, __m512i
count);
```

Shifts packed int32 elements in *a* right by the amount specified by the corresponding element in *count* while shifting in sign bits, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_srav_epi32

```
extern __m512i __cdecl _mm512_maskz_srav_epi32(__mmask16 k, __m512i a, __m512i count);
```

Shifts packed int32 elements in *a* right by the amount specified by the corresponding element in *count* while shifting in sign bits, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srav_epi64

```
extern __m512i __cdecl _mm512_srav_epi64(__m512i a, __m512i count);
```

Shifts packed int64 elements in *a* right by the amount specified by the corresponding element in *count* while shifting in sign bits, and stores the result.

_mm512_mask_srav_epi64

```
extern __m512i __cdecl _mm512_mask_srav_epi64(__m512i src, __mmask8 k, __m512i a, __m512i count);
```

Shifts packed int64 elements in *a* right by the amount specified by the corresponding element in *count* while shifting in sign bits, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_srav_epi64

```
extern __m512i __cdecl _mm512_maskz_srav_epi64(__mmask8 k, __m512i a, __m512i count);
```

Shifts packed int64 elements in *a* right by the amount specified by the corresponding element in *count* while shifting in sign bits, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srl_epi32

```
extern __m512i __cdecl _mm512_srl_epi32(__m512i a, __m128i count);
```

Shifts packed int32 elements in *a* right by *count* while shifting in zeros, and stores the result.

_mm512_mask_srl_epi32

```
extern __m512i __cdecl _mm512_mask_srl_epi32(__m512i src, __mmask16 k, __m512i a, __m128i count);
```

Shifts packed int32 elements in *a* right by *count* while shifting in zeros, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_srl_epi32

```
extern __m512i __cdecl _mm512_maskz_srl_epi32(__mmask16 k, __m512i a, __m128i count);
```

Shifts packed int32 elements in *a* right by *count* while shifting in zeros, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srli_epi32

```
extern __m512i __cdecl _mm512_srli_epi32(__m512i a, unsigned int imm);
```

Shifts packed int32 elements in *a* right by *imm* while shifting in zeros, and stores the result.

_mm512_mask_srli_epi32

```
extern __m512i __cdecl _mm512_mask_srli_epi32(__m512i src, __mmask16 k, __m512i a, unsigned int
imm);
```

Shifts packed int32 elements in *a* right by *imm* while shifting in zeros, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_srli_epi32

```
extern __m512i __cdecl _mm512_maskz_srli_epi32(__mmask16 k, __m512i a, unsigned int imm);
```

Shifts packed int32 elements in *a* right by *imm* while shifting in zeros, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srl_epi64

```
extern __m512i __cdecl _mm512_srl_epi64(__m512i a, __m128i count);
```

Shifts packed int64 elements in *a* right by *count* while shifting in zeros, and stores the result.

_mm512_mask_srl_epi64

```
extern __m512i __cdecl _mm512_mask_srl_epi64(__m512i src, __mmask8 k, __m512i a, __m128i count);
```

Shifts packed int64 elements in *a* right by *count* while shifting in zeros, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_srl_epi64

```
extern __m512i __cdecl _mm512_maskz_srl_epi64(__mmask8 k, __m512i a, __m128i count);
```

Shifts packed int64 elements in *a* right by *count* while shifting in zeros, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srli_epi64

```
extern __m512i __cdecl _mm512_srli_epi64(__m512i a, unsigned int imm);
```

Shifts packed int64 elements in *a* right by *imm* while shifting in zeros, and stores the result.

_mm512_mask_srli_epi64

```
extern __m512i __cdecl _mm512_mask_srli_epi64(__m512i src, __mmask8 k, __m512i a, unsigned int
imm);
```

Shifts packed int64 elements in *a* right by *imm* while shifting in zeros, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_srli_epi64

```
extern __m512i __cdecl _mm512_maskz_srli_epi64(__mmask8 k, __m512i a, unsigned int imm);
```

Shifts packed int64 elements in *a* right by *imm* while shifting in zeros, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srlv_epi32

```
extern __m512i __cdecl _mm512_srlv_epi32(__m512i a, __m512i count);
```

Shifts packed int32 elements in *a* right by the amount specified by the corresponding element in *count* while shifting in zeros, and stores the result.

_mm512_mask_srlv_epi32

```
extern __m512i __cdecl _mm512_mask_srlv_epi32(__m512i src, __mmask16 k, __m512i a, __m512i
count);
```

Shifts packed int32 elements in *a* right by the amount specified by the corresponding element in *count* while shifting in zeros, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_srlv_epi32

```
extern __m512i __cdecl _mm512_maskz_srlv_epi32(__mmask16 k, __m512i a, __m512i count);
```

Shifts packed int32 elements in *a* right by the amount specified by the corresponding element in *count* while shifting in zeros, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_srlv_epi64

```
extern __m512i __cdecl _mm512_srlv_epi64(__m512i a, __m512i count);
```

Shifts packed int64 elements in *a* right by the amount specified by the corresponding element in *count* while shifting in zeros, and stores the result.

_mm512_mask_srlv_epi64

```
extern __m512i __cdecl _mm512_mask_srlv_epi64(__m512i src, __mmask8 k, __m512i a, __m512i count);
```

Shifts packed int64 elements in *a* right by the amount specified by the corresponding element in *count* while shifting in zeros, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_srlv_epi64

```
extern __m512i __cdecl _mm512_maskz_srlv_epi64(__mmask8 k, __m512i a, __m512i count);
```

Shifts packed int64 elements in *a* right by the amount specified by the corresponding element in *count* while shifting in zeros, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Broadcast Operations

Intrinsics for FP Broadcast Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_broadcast_f32x4`, `_mm512_mask_broadcast_f32x4`, `_mm512_maskz_broadcast_f32x4`	Broadcast float32 element to four destination locations.	`VBROADCASTF32X4`
`_mm512_broadcast_f64x4`, `_mm512_mask_broadcast_f64x4`, `_mm512_maskz_broadcast_f64x4`	Broadcast float64 element to four destination locations.	`VBROADCASTF64X4`
`_mm512_broadcastsd_pd`, `_mm512_mask_broadcastsd_pd`, `_mm512_maskz_broadcastsd_pd`	Broadcast packed float64 element to all destination locations.	`VBROADCASTSD`
`_mm512_broadcastss_ps`, `_mm512_mask_broadcastss_ps`, `_mm512_maskz_broadcastss_ps`	Broadcast packed float32 element to all destination locations.	`VBROADCASTSS`

variable	definition
k	writemask used as a selector
a	first source vector element
src	source element to use based on writemask result

_mm512_broadcast_f32x4

```
extern __m512 __cdecl _mm512_broadcast_f32x4(__m128 a);
```

Broadcasts four packed float32 elements from *a* to all destination elements.

_mm512_mask_broadcast_f32x4

```
extern __m512 __cdecl _mm512_mask_broadcast_f32x4(__m512 src, __mmask16 k, __m128 a);
```

Broadcasts four packed float32 elements from *a* to all destination elements using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_broadcast_f32x4

```
extern __m512 __cdecl _mm512_maskz_broadcast_f32x4(__mmask16 k, __m128 a);
```

Broadcasts four packed float32 elements from *a* to all destination elements using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_broadcast_f64x4

```
extern __m512d __cdecl _mm512_broadcast_f64x4(__m256d a);
```

Broadcasts four packed float64 elements from *a* to all destination elements.

_mm512_mask_broadcast_f64x4

```
extern __m512d __cdecl _mm512_mask_broadcast_f64x4(__m512d src, __mmask8 k, __m256d a);
```

Broadcasts four packed float64 elements from *a* to all destination elements using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_broadcast_f64x4

```
extern __m512d __cdecl _mm512_maskz_broadcast_f64x4(__mmask8 k, __m256d a);
```

Broadcasts four packed float64 elements from *a* to all destination elements using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_broadcastsd_pd

```
extern __m512d __cdecl _mm512_broadcastsd_pd(__m128d a);
```

Broadcasts low float64 element from *a* to all destination elements.

_mm512_mask_broadcastsd_pd

```
extern __m512d __cdecl _mm512_mask_broadcastsd_pd(__m512d src, __mmask8 k, __m128d a);
```

Broadcasts low float64 element from *a* to all destination elements using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_broadcastsd_pd

```
extern __m512d __cdecl _mm512_maskz_broadcastsd_pd(__mmask8 k, __m128d a);
```

Broadcasts low float64 element from *a* to all destination elements using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_broadcastss_ps

```
extern __m512 __cdecl _mm512_broadcastss_ps(__m128 a);
```

Broadcasts low float32 element from *a* to all destination elements.

_mm512_mask_broadcastss_ps

```
extern __m512 __cdecl _mm512_mask_broadcastss_ps(__m512 src, __mmask16 k, __m128 a);
```

Broadcasts low float32 element from *a* to all destination elements using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_broadcastss_ps

```
extern __m512 __cdecl _mm512_maskz_broadcastss_ps(__mmask16 k, __m128 a);
```

Broadcasts low float32 element from *a* to all destination elements using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Integer Broadcast Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_broadcast_i32x4`, `_mm512_mask_broadcast_i32x4`, `_mm512_maskz_broadcast_i32x4`	Broadcasts source int32 element to four destinations.	`VBROADCASTI32X4`
`_mm512_broadcast_i64x4`, `_mm512_mask_broadcast_i64x4`, `_mm512_maskz_broadcast_i64x4`	Broadcasts source int64 element to four destinations.	`VBROADCASTI64X4`
`_mm512_broadcastd_epi32`, `_mm512_mask_broadcastd_epi32`, `_mm512_maskz_broadcastd_epi32`	Broadcasts source int32 element to doubleword destinations.	`VPBROADCASTD`
`_mm512_broadcastq_epi64`, `_mm512_mask_broadcastq_epi64`, `_mm512_maskz_broadcastq_epi64`	Broadcasts source int64 element to quadword destinations.	`VPBROADCASTQ`
`_mm512_broadcastmb_epi64`	Broadcasts low byte from input mask to all int64 destination elements.	`VPBROADCASTMB2Q`
`_mm512_broadcastmw_epi32`	Broadcasts low word from input mask to all int32 destination elements.	`VPBROADCASTMD2W`

variable	definition
k	writemask used as a selector
a	first source vector element
src	source element to use based on writemask result

_mm512_broadcast_i32x4

```
extern __m512i __cdecl _mm512_broadcast_i32x4(__m128i a);
```

Broadcasts four packed int32 elements from *a* to all destination elements.

_mm512_mask_broadcast_i32x4

```
extern __m512i __cdecl _mm512_mask_broadcast_i32x4(__m512i src, __mmask16 k, __m128i a);
```

Broadcasts four packed int32 elements from *a* to all destination elements using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_broadcast_i32x4

```
extern __m512i __cdecl _mm512_maskz_broadcast_i32x4(__mmask16 k, __m128i a);
```

Broadcasts four packed int32 elements from *a* to all destination elements using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_broadcast_i64x4

```
extern __m512i __cdecl _mm512_broadcast_i64x4(__m256i a);
```

Broadcasts four packed int64 elements from *a* to all destination elements.

_mm512_mask_broadcast_i64x4

```
extern __m512i __cdecl _mm512_mask_broadcast_i64x4(__m512i src, __mmask8 k, __m256i a);
```

Broadcasts four packed int64 elements from *a* to all destination elements using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_broadcast_i64x4

```
extern __m512i __cdecl _mm512_maskz_broadcast_i64x4(__mmask8 k, __m256i a);
```

Broadcasts four packed int64 elements from *a* to all destination elements using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_broadcastd_epi32

```
extern __m512i __cdecl _mm512_broadcastd_epi32(__m128i a);
```

Broadcasts low packed 32-bit integer from *a* to all elements.

_mm512_mask_broadcastd_epi32

```
extern __m512i __cdecl _mm512_mask_broadcastd_epi32(__m512i src, __mmask16 k, __m128i a);
```

Broadcasts low packed 32-bit integer from *a* to all destination elements using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_broadcastd_epi32

```
extern __m512i __cdecl _mm512_maskz_broadcastd_epi32(__mmask16 k, __m128i a);
```

Broadcasts low packed 32-bit integer from *a* to all destination elements using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_broadcastq_epi64

```
extern __m512i __cdecl _mm512_broadcastq_epi64(__m128i a);
```

Broadcasts low packed 64-bit integer from *a* to all destination elements.

_mm512_mask_broadcastq_epi64

```
extern __m512i __cdecl _mm512_mask_broadcastq_epi64(__m512i src, __mmask8 k, __m128i a);
```

Broadcasts low packed 64-bit integer from *a* to all destination elements using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_broadcastq_epi64

```
extern __m512i __cdecl _mm512_maskz_broadcastq_epi64(__mmask8 k, __m128i a);
```

Broadcasts low packed 64-bit integer from *a* to all destination elements using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_broadcastmw_epi32

```
extern __m512i __cdecl _mm512_broadcastmw_epi32(__mmask16 k);
```

Broadcasts low 16-bits from input mask *k* to all 32-bit elements of destination.

_mm512_broadcastmb_epi64

```
extern __m512i __cdecl _mm512_broadcastmb_epi64(__mmask8 k);
```

Broadcasts the low 8-bits from input mask *k* to all 64-bit elements of destination.

Intrinsics for Comparison Operations

Intrinsics for FP Comparison Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_cmp_round_pd_mask`, `_mm512_mask_cmp_round_pd_mask` `_mm512_cmp_pd_mask`, `_mm512_mask_cmp_pd_mask`, `_mm512_cmp_round_pd_mask`,	Compares float64 vector elements based on comparison operand.	`VCMPPD`

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_mask_cmp_round_pd_mask, _mm512_cmpeq_pd_mask, _mm512_mask_cmpeq_pd_mask, _mm512_cmple_pd_mask, _mm512_mask_cmple_pd_mask, _mm512_cmplt_pd_mask, _mm512_mask_cmplt_pd_mask, _mm512_cmpneq_pd_mask, _mm512_cmplt_pd_mask, _mm512_cmpneq_pd_mask, _mm512_mask_cmpneq_pd_mask, _mm512_cmpnle_pd_mask, _mm512_mask_cmpnle_pd_mask, _mm512_cmpnlt_pd_mask, _mm512_mask_cmpnlt_pd_mask, _mm512_cmpord_pd_mask, _mm512_mask_cmpord_pd_mask, _mm512_cmpunord_pd_mask, _mm512_mask_cmpunord_pd_mask		
_mm512_cmp_round_ps_mask, _mm512_mask_cmp_round_ps_mask	Compares float32 vector elements based on comparison operand.	VCMPPS
_mm512_cmp_ps_mask, _mm512_mask_cmp_ps_mask, _mm512_cmp_round_ps_mask, _mm512_mask_cmp_round_ps_mask, _mm512_cmpeq_ps_mask, _mm512_mask_cmpeq_ps_mask, _mm512_cmple_ps_mask, _mm512_mask_cmple_ps_mask, _mm512_cmplt_ps_mask, _mm512_mask_cmplt_ps_mask, _mm512_cmpneq_ps_mask, _mm512_mask_cmpneq_ps_mask, _mm512_cmpnle_ps_mask, _mm512_mask_cmpnle_ps_mask, _mm512_cmpnlt_ps_mask, _mm512_mask_cmpnlt_ps_mask, _mm512_cmpord_ps_mask, _mm512_mask_cmpord_ps_mask, _mm512_cmpunord_ps_mask, _mm512_mask_cmpunord_ps_mask		
_mm_cmp_sd_mask, _mm_mask_cmp_sd_mask, _mm_cmp_round_sd_mask, _mm_mask_cmp_sd_mask	Compares lower float64 vector elements based on comparison operand.	VCMPSD

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm_cmp_ss_mask`, `_mm_mask_cmp_ss_mask`, `_mm_cmp_round_ss_mask`, `_mm_mask_cmp_ss_mask`	Compares lower float32 vector elements based on comparison operand.	`VCMPSS`

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result
round	Rounding control values; these can be one of the following (along with the `sae` suppress all exceptions flag): • `_MM_FROUND_TO_NEAREST_INT` - rounds to nearest even • `_MM_FROUND_TO_NEG_INF` - rounds to negative infinity • `_MM_FROUND_TO_POS_INF` - rounds to positive infinity • `_MM_FROUND_TO_ZERO` - rounds to zero • `_MM_FROUND_CUR_DIRECTION` - rounds using default from MXCSR register
imm	comparison predicate, which can be any of the following values: • `_MM_CMPINT_EQ` - Equal • `_MM_CMPINT_LT` - Less than • `_MM_CMPINT_LE` - Less than or Equal • `_MM_CMPINT_NE` - Not Equal • `_MM_CMPINT_NLT` - Not Less than • `_MM_CMPINT_GE` - Greater than or Equal • `_MM_CMPINT_NLE` - Not Less than or Equal • `_MM_CMPINT_GT` - Greater than

_mm512_cmp_pd_mask

```
extern __mmask8 __cdecl _mm512_cmp_pd_mask(__m512d a, __m512d b, const int imm);
```

Compares float64 elements in *a* and *b* based on the comparison operand specified by *imm*.

The result is stored in mask vector.

_mm512_cmp_round_pd_mask

```
extern __mmask8 __cdecl _mm512_cmp_round_pd_mask(__m512d a, __m512d b, const int imm, const int
round);
```

Compares float64 elements in *a* and *b* based on the comparison operand specified by *imm*.

The result is stored in mask vector.

NOTE
Pass `__MM_FROUND_NO_EXC` to *round* to suppress all exceptions.

_mm512_mask_cmp_round_pd_mask

```
extern __mmask8 __cdecl _mm512_mask_cmp_round_pd_mask(__mmask8 k, __m512d a, __m512d b, const
int imm, const int round);
```

Compares float64 elements in *a* and *b* based on the comparison operand specified by *imm*.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

NOTE
Pass `__MM_FROUND_NO_EXC` to *round* to suppress all exceptions.

_mm512_mask_cmp_pd_mask

```
extern __mmask8 __cdecl _mm512_mask_cmp_pd_mask(__mmask8 k, __m512d a, __m512d b, const int imm);
```

Compares float64 elements in *a* and *b* based on the comparison operand specified by *imm*.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpeq_pd_mask

```
extern __mmask8 __cdecl _mm512_cmp_pd_mask(__m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* for equality.

The result is stored in mask vector.

_mm512_mask_cmpeq_pd_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpeq_pd_mask(__mmask8 k, __m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* for equality.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmple_pd_mask

```
extern __mmask8 __cdecl _mm512_cmple_pd_mask(__m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* for less-than-or-equal.

The result is stored in mask vector.

_mm512_mask_cmple_pd_mask

```
extern __mmask8 __cdecl _mm512_mask_cmple_pd_mask(__mmask8 k, __m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* for less-than-or-equal.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmplt_pd_mask

```
extern __mmask8 __cdecl _mm512_cmplt_pd_mask(__m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* for less-than.

The result is stored in mask vector.

_mm512_mask_cmplt_pd_mask

```
extern __mmask8 __cdecl _mm512_mask_cmplt_pd_mask(__mmask8 k, __m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* for less-than.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpneq_pd_mask

```
extern __mmask8 __cdecl _mm512_cmpneq_pd_mask(__m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* for not-equal.

The result is stored in mask vector.

_mm512_mask_cmpneq_pd_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpneq_pd_mask(__mmask8 k, __m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* for not-equal.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpnle_pd_mask

```
extern __mmask8 __cdecl _mm512_cmpnle_pd_mask(__m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* for not-less-than-or-equal.

The result is stored in mask vector.

_mm512_mask_cmpnle_pd_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpnle_pd_mask(__mmask8 k, __m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* for not-less-than-or-equal.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpnlt_pd_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpnlt_pd_mask(__m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* for not-less-than.

The result is stored in mask vector.

_mm512_mask_cmpnlt_pd_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpnlt_pd_mask(__mmask8 k, __m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* for not-less-than.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpord_pd_mask

```
extern __mmask8 __cdecl _mm512_cmpord_pd_mask(__m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* to see if neither is NaN.

The result is stored in mask vector.

_mm512_mask_cmpord_pd_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpord_pd_mask(__mmask8 k, __m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* to see if neither is NaN.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpunord_pd_mask

```
extern __mmask8 __cdecl _mm512_cmpunord_pd_mask(__m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* to see if either is NaN.

The result is stored in mask vector.

_mm512_mask_cmpord_pd_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpord_pd_mask(__mmask8 k, __m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* to see if neither is NaN.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mask_cmpunord_pd_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpord_pd_mask(__mmask8 k, __m512d a, __m512d b);
```

Compares float64 elements in *a* and *b* to see if either is NaN.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmp_ps_mask

```
extern __mmask16 __cdecl _mm512_cmp_ps_mask(__m512 a, __m512 b, const int imm);
```

Compares float32 elements in *a* and *b* based on the comparison operand specified by *imm*.

The result is stored in mask vector.

_mm512_mask_cmp_ps_mask

```
extern __mmask16 __cdecl _mm512_mask_cmp_ps_mask(__mmask16 k, __m512 a, __m512 b, const int imm);
```

Compares float32 elements in *a* and *b* based on the comparison operand specified by *imm*.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmp_round_ps_mask

```
extern __mmask16 __cdecl _mm512_cmp_round_ps_mask(__m512 a, __m512 b, const int imm, const int
round);
```

Compares float32 elements in *a* and *b* based on the comparison operand specified by *imm*.

The result is stored in mask vector.

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *round* to suppress all exceptions.

_mm512_mask_cmp_round_ps_mask

```
extern __mmask16 __cdecl _mm512_mask_cmp_round_ps_mask(__mmask16 k, __m512 a, __m512 b, const
int imm, const int round);
```

Compares float32 elements in *a* and *b* based on the comparison operand specified by *imm*.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *round* to suppress all exceptions.

_mm512_cmpeq_ps_mask

```
extern __mmask16 __cdecl _mm512_cmpeq_ps_mask(__m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* for equality.

The result is stored in mask vector.

_mm512_mask_cmpeq_ps_mask

```
extern __mmask16 __cdecl _mm512_mask_cmpeq_ps_mask(__mmask16 k, __m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* for equality.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmple_ps_mask

```
extern __mmask16 __cdecl _mm512_cmple_ps_mask(__m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* for less-than-or-equal.

The result is stored in mask vector.

_mm512_mask_cmple_ps_mask

```
extern __mmask16 __cdecl _mm512_mask_cmple_ps_mask(__mmask16 k, __m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* for less-than-or-equal.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpunord_ps_mask

```
extern __mmask16 __cdecl _mm512_cmpunord_ps_mask(__m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* to see if either is NaN.

The result is stored in mask vector.

_mm512_mask_cmpunord_ps_mask

```
extern __mmask16 __cdecl _mm512_mask_cmpunord_ps_mask(__mmask16 k, __m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* to see if neither is NaN.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmplt_ps_mask

```
extern __mmask16 __cdecl _mm512_cmplt_ps_mask(__m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* for less-than.

The result is stored in mask vector.

_mm512_mask_cmplt_ps_mask

```
extern __mmask16 __cdecl _mm512_mask_cmplt_ps_mask(__mmask16 k, __m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* for less-than.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpneq_ps_mask

```
extern __mmask16 __cdecl _mm512_cmpneq_ps_mask(__m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* for not-equal.

The result is stored in mask vector.

_mm512_mask_cmpneq_ps_mask

```
extern __mmask16 __cdecl _mm512_mask_cmpneq_ps_mask(__mmask16 k, __m512 a, __m512 b, const int
round);
```

Compares float32 elements in *a* and *b* for not-equal.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpnle_ps_mask

```
extern __mmask16 __cdecl _mm512_cmpnle_ps_mask(__m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* for not-less-than-or-equal.

The result is stored in mask vector.

_mm512_mask_cmpnle_ps_mask

```
extern __mmask16 __cdecl _mm512_mask_cmpnle_ps_mask(__mmask16 k, __m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* for not-less-than-or-equal.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpnlt_ps_mask

```
extern __mmask16 __cdecl _mm512_cmpnlt_ps_mask(__m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* for not-less-than.

The result is stored in mask vector.

_mm512_mask_cmpnlt_ps_mask

```
extern __mmask16 __cdecl _mm512_mask_cmpnlt_ps_mask(__mmask16 k, __m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* for not-less-than.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpord_ps_mask

```
extern __mmask16 __cdecl _mm512_cmpord_ps_mask(__m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* to see if either is NaN.

The result is stored in mask vector.

_mm512_mask_cmpord_ps_mask

```
extern __mmask16 __cdecl _mm512_mask_cmpord_ps_mask(__mmask16 k, __m512 a, __m512 b);
```

Compares float32 elements in *a* and *b* to see if either is NaN.

The result is stored in mask vector using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm_cmp_round_sd_mask

```
extern __mmask8 __cdecl _mm_cmp_round_sd_mask(__m128d a, __m128d b, const int imm, const round);
```

Compares lower float64 elements in *a* and *b* based on the comparison operand specified by *imm*.

The result is stored in mask vector.

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *round* to suppress all exceptions.

_mm_mask_cmp_round_sd_mask

```
extern __mmask8 __cdecl _mm_mask_cmp_round_sd_mask(__mmask8 k, __m128d a, __m128d b, const int
imm, const int round);
```

Compares lower float64 elements in *a* and *b* based on the comparison operand specified by *imm*, and store the result in mask vector *k* using zeromask *k* (the element is zeroed out when mask bit 0 is not set).

NOTE
Pass `__MM_FROUND_NO_EXC` to *round* to suppress all exceptions.

_mm_cmp_sd_mask

```
extern __mmask8 __cdecl _mm_cmp_sd_mask(__m128d a, __m128d b, const int imm);
```

Compares lower float64 elements in *a* and *b* based on the comparison operand specified by *imm*.

The result is stored in mask vector.

_mm_mask_cmp_sd_mask

```
extern __mmask8 __cdecl _mm_mask_cmp_sd_mask(__mmask8 k, __m128d a, __m128d b, const int imm);
```

Compares lower float64 elements in *a* and *b* based on the comparison operand specified by *imm*

The result is stored in mask vector using zeromask *k* (the element is zeroed out when mask bit 0 is not set).

_mm_cmp_round_ss_mask

```
extern __mmask8 __cdecl _mm_cmp_round_ss_mask(__m128 a, __m128 b, const int imm, const int
round);
```

Compares lower float32 elements in *a* and *b* based on the comparison operand specified by *imm*.

The result is stored in mask vector.

NOTE
Pass `__MM_FROUND_NO_EXC` to *round* to suppress all exceptions.

_mm_mask_cmp_round_ss_mask

```
extern __mmask8 __cdecl _mm_mask_cmp_round_ss_mask(__mmask8 k, __m128 a, __m128 b, const int
imm, const int round);
```

Compares lower float32 elements in *a* and *b* based on the comparison operand specified by *imm*.

The result is stored in mask vector using zeromask *k* (the element is zeroed out when mask bit 0 is not set).

NOTE
Pass `__MM_FROUND_NO_EXC` to *round* to suppress all exceptions.

_mm_cmp_ss_mask

```
extern __mmask8 __cdecl _mm_cmp_ss_mask(__m128 a, __m128 b, const int imm);
```

Compares lower float32 elements in *a* and *b* based on the comparison operand specified by *imm*.

The result is stored in mask vector.

_mm_mask_cmp_ss_mask

```
extern __mmask8 __cdecl _mm_mask_cmp_ss_mask(__mmask8 k, __m128 a, __m128 b, const int imm);
```

Compares lower float32 elements in *a* and *b* based on the comparison operand specified by *imm*.

The result is stored in mask vector using zeromask *k* (the element is zeroed out when mask bit 0 is not set).

Intrinsics for Integer Comparison Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_cmp_epi32_mask` `_mm512_cmpeq_epi32_mask`, `_mm512_cmpge_epi32_mask`, `_mm512_cmpgt_epi32_mask`, `_mm512_cmple_epi32_mask`, `_mm512_cmplt_epi32_mask`, `_mm512_cmpneq_epi32_mask`, `_mm512_mask_cmp_epi32_mask`, `_mm512_mask_cmpeq_epi32_mask`, `_mm512_mask_cmpge_epi32_mask`, `_mm512_mask_cmpgt_epi32_mask`, `_mm512_mask_cmple_epi32_mask`, `_mm512_mask_cmplt_epi32_mask`, `_mm512_mask_cmpneq_epi32_mask`	Compare signed int32 elements based on the comparison operand.	`VPCMPD`
`_mm512_cmp_epi64_mask`, `_mm512_mask_cmp_epi64_mask` `_mm512_cmpeq_epi64_mask`, `_mm512_cmpge_epi64_mask`, `_mm512_cmpgt_epi64_mask`, `_mm512_cmple_epi64_mask`, `_mm512_cmplt_epi64_mask`, `_mm512_cmpneq_epi64_mask`, `_mm512_mask_cmp_epi64_mask`, `_mm512_mask_cmpeq_epi64_mask`, `_mm512_mask_cmpge_epi64_mask`,	Compare signed int64 elements based on the comparison operand.	`VPCMPQ`

ask, _mm512_mask_cmple_epu64_mask, _mm512_mask_cmplt_epu64_mask, _mm512_mask_cmpneq_epu64_mask		

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result
imm	comparison operand
src	source element

_mm_comi_round_sd

```
extern int __cdecl _mm_comi_round_sd(__m128d a, __m128d b, const int imm, const int sae);
```

Compare the lower double-precision (64-bit) floating-point element in *a* and *b* based on the comparison operand specified by *imm*, and return the boolean result (0 or 1).

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm_comi_round_ss

```
extern int __cdecl _mm_comi_round_ss(__m128 a, __m128 b, const int imm, const int sae);
```

Compare the lower single-precision (32-bit) floating-point element in *a* and *b* based on the comparison operand specified by *imm*, and return the boolean result (0 or 1).

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_cmp_epi32_mask

```
extern __mmask16 __cdecl _mm512_cmp_epi32_mask(__m512i a, __m512i b, const int imm);
```

Compare packed int32 elements in *a* and *b* based on the comparison operand specified by *imm*, and store the results in mask vector *k*.

_mm512_mask_cmp_epi32_mask

```
extern __mmask16 __cdecl _mm512_mask_cmp_epi32_mask(__mmask16 k, __m512i a, __m512i b, const int
imm);
```

Compare packed int32 elements in *a* and *b* based on the comparison operand specified by *imm*, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpeq_epi32_mask

```
extern __mmask16 __cdecl _mm512_cmpeq_epi32_mask(__m512i a, __m512i b);
```

Compare packed int32 elements in *a* and *b* for equality, and store the results in mask vector *k*.

_mm512_mask_cmpeq_epi32_mask

```
 extern __mmask16 __cdecl  _mm512_mask_cmpeq_epi32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed int32 elements in *a* and *b* for equality, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpge_epi32_mask

```
extern __mmask16 __cdecl  _mm512_cmpge_epi32_mask(__m512i a, __m512i b);
```

Compare packed int32 elements in *a* and *b* for greater-than-or-equal, and store the results in mask vector *k*.

_mm512_mask_cmpge_epi32_mask

```
extern __mmask16 __cdecl  _mm512_mask_cmpge_epi32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed int32 elements in *a* and *b* for greater-than-or-equal, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpgt_epi32_mask

```
extern __mmask16 __cdecl  _mm512_cmpgt_epi32_mask(__m512i a, __m512i b);
```

Compare packed int32 elements in *a* and *b* for greater-than, and store the results in mask vector *k*.

_mm512_mask_cmpgt_epi32_mask

```
extern __mmask16 __cdecl  _mm512_mask_cmpgt_epi32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed int32 elements in *a* and *b* for greater-than, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmple_epi32_mask

```
extern __mmask16 __cdecl  _mm512_cmple_epi32_mask(__m512i a, __m512i b);
```

Compare packed int32 elements in *a* and *b* for less-than-or-equal, and store the results in mask vector *k*.

_mm512_mask_cmple_epi32_mask

```
extern __mmask16 __cdecl  _mm512_mask_cmple_epi32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed int32 elements in *a* and *b* for less-than, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmplt_epi32_mask

```
extern __mmask16 __cdecl  _mm512_cmplt_epi32_mask(__m512i a, __m512i b);
```

Compare packed int32 elements in *a* and *b* for less-than, and store the results in mask vector *k*.

_mm512_mask_cmplt_epi32_mask

```
extern __mmask16 __cdecl  _mm512_mask_cmplt_epi32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed int32 elements in *a* and *b* for less-than-or-equal, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpneq_epi32_mask

```
extern __mmask16 __cdecl  _mm512_cmpneq_epi32_mask(__m512i a, __m512i b);
```

Compare packed int32 elements in *a* and *b* for not-equal, and store the results in mask vector *k*.

_mm512_mask_cmpneq_epi32_mask

```
extern __mmask16 __cdecl  _mm512_mask_cmpneq_epi32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed int32 elements in *a* and *b* for not-equal, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmp_epi64_mask

```
extern __mmask8 __cdecl _mm512_cmp_epi64_mask(__m512i a, __m512i b, const int imm);
```

Compare packed int64 elements in *a* and *b* based on the comparison operand specified by *imm*, and store the results in mask vector *k*.

_mm512_mask_cmp_epi64_mask

```
extern __mmask8 __cdecl _mm512_mask_cmp_epi64_mask(__mmask8 k, __m512i a, __m512i b, const int
imm);
```

Compare packed int64 elements in *a* and *b* based on the comparison operand specified by *imm*, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpeq_epi64_mask

```
extern __mmask8 __cdecl _mm512_cmpeq_epi64_mask(__m512i a, __m512i b);
```

Compare packed int64 elements in *a* and *b* for equality, and store the results in mask vector *k*.

_mm512_mask_cmpeq_epi64_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpeq_epi64_mask(__mmask8 k, __m512i a, __m512i b);
```

Compare packed int64 elements in *a* and *b* for equality, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpge_epi64_mask

```
extern __mmask8 __cdecl _mm512_cmpge_epi64_mask(__m512i a, __m512i b);
```

Compare packed int64 elements in *a* and *b* for greater-than-or-equal, and store the results in mask vector *k*.

_mm512_mask_cmpge_epi64_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpge_epi64_mask(__mmask8 k, __m512i a, __m512i b);
```

Compare packed int64 elements in *a* and *b* for greater-than-or-equal, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpgt_epi64_mask

```
extern __mmask8 __cdecl _mm512_cmpgt_epi64_mask(__m512i a, __m512i b);
```

Compare packed int64 elements in *a* and *b* for greater-than, and store the results in mask vector *k*.

_mm512_mask_cmpgt_epi64_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpgt_epi64_mask(__mmask8 k, __m512i a, __m512i b);
```

Compare packed int64 elements in *a* and *b* for greater-than, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmple_epi64_mask

```
extern __mmask8 __cdecl _mm512_cmple_epi64_mask(__m512i a, __m512i b);
```

Compare packed int64 elements in *a* and *b* for less-than-or-equal, and store the results in mask vector *k*.

_mm512_mask_cmple_epi64_mask

```
extern __mmask8 __cdecl _mm512_mask_cmple_epi64_mask(__mmask8 k, __m512i a, __m512i b);
```

Compare packed int64 elements in *a* and *b* for less-than-or-equal, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmplt_epi64_mask

```
extern __mmask8 __cdecl _mm512_cmplt_epi64_mask(__m512i a, __m512i b);
```

Compare packed int64 elements in *a* and *b* for less-than, and store the results in mask vector *k*.

_mm512_mask_cmplt_epi64_mask

```
extern __mmask8 __cdecl _mm512_mask_cmplt_epi64_mask(__mmask8 k, __m512i a, __m512i b);
```

Compare packed int64 elements in *a* and *b* for less-than, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpneq_epi64_mask

```
extern __mmask8 __cdecl _mm512_cmpneq_epi64_mask(__m512i a, __m512i b);
```

Compare packed int64 elements in *a* and *b* for not-equal, and store the results in mask vector *k*.

_mm512_mask_cmpneq_epi64_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpneq_epi64_mask(__mmask8 k, __m512i a, __m512i b);
```

Compare packed int64 elements in *a* and *b* for not-equal, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmp_epu32_mask

```
extern __mmask16 __cdecl _mm512_cmp_epu32_mask(__m512i a, __m512i b, const int imm);
```

Compare packed unsigned int32 elements in *a* and *b* based on the comparison operand specified by *imm*, and store the results in mask vector *k*.

_mm512_mask_cmp_epu32_mask

```
extern __mmask16 __cdecl _mm512_mask_cmp_epu32_mask(__mmask16 k, __m512i a, __m512i b, const int
imm);
```

Compare packed unsigned int32 elements in *a* and *b* based on the comparison operand specified by *imm*, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpeq_epu32_mask

```
extern __mmask16 __cdecl  _mm512_cmpeq_epu32_mask(__m512i a, __m512i b);
```

Compare packed unsigned int32 elements in *a* and *b* for equality, and store the results in mask vector *k*.

_mm512_mask_cmpeq_epu32_mask

```
extern __mmask16 __cdecl  _mm512_mask_cmpeq_epu32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed unsigned int32 elements in *a* and *b* for equality, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpge_epu32_mask

```
extern __mmask16 __cdecl  _mm512_cmpge_epu32_mask(__m512i a, __m512i b);
```

Compare packed unsigned int32 elements in *a* and *b* for greater-than-or-equal, and store the results in mask vector *k*.

_mm512_mask_cmpge_epu32_mask

```
extern __mmask16 __cdecl  _mm512_mask_cmpge_epu32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed unsigned int32 elements in *a* and *b* for greater-than-or-equal, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpgt_epu32_mask

```
extern __mmask16 __cdecl  _mm512_cmpgt_epu32_mask(__m512i a, __m512i b);
```

Compare packed unsigned int32 elements in *a* and *b* for greater-than, and store the results in mask vector *k*.

_mm512_mask_cmpgt_epu32_mask

```
extern __mmask16 __cdecl  _mm512_mask_cmpgt_epu32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed unsigned int32 elements in *a* and *b* for greater-than, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmple_epu32_mask

```
extern __mmask16 __cdecl  _mm512_cmple_epu32_mask(__m512i a, __m512i b);
```

Compare packed unsigned int32 elements in *a* and *b* for less-than-or-equal, and store the results in mask vector *k*.

_mm512_mask_cmple_epu32_mask

```
extern __mmask16 __cdecl  _mm512_mask_cmple_epu32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed unsigned int32 elements in *a* and *b* for less-than, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmplt_epu32_mask

```
extern __mmask16 __cdecl  _mm512_cmplt_epu32_mask(__m512i a, __m512i b);
```

Compare packed unsigned int32 elements in *a* and *b* for less-than, and store the results in mask vector *k*.

_mm512_mask_cmplt_epu32_mask

```
extern __mmask16 __cdecl  _mm512_mask_cmplt_epu32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed unsigned int32 elements in *a* and *b* for less-than-or-equal, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpneq_epu32_mask

```
extern __mmask16 __cdecl  _mm512_cmpneq_epu32_mask(__m512i a, __m512i b);
```

Compare packed unsigned int32 elements in *a* and *b* for not-equal, and store the results in mask vector *k*.

_mm512_mask_cmpneq_epu32_mask

```
extern __mmask16 __cdecl  _mm512_mask_cmpneq_epu32_mask(__mmask16 k, __m512i a, __m512i b);
```

Compare packed unsigned int32 elements in *a* and *b* for not-equal, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmp_epu64_mask

```
extern __mmask8 __cdecl _mm512_cmp_epu64_mask(__m512i a, __m512i b, const _MM_CMPINT_ENUM imm);
```

Compare packed unsigned int64 elements in *a* and *b* based on the comparison operand specified by *imm*, and store the results in mask vector *k*.

_mm512_mask_cmp_epu64_mask

```
extern __mmask8 __cdecl _mm512_mask_cmp_epu64_mask(__mmask8 k, __m512i a, __m512i b, const
_MM_CMPINT_ENUM imm);
```

Compare packed unsigned int64 elements in *a* and *b* based on the comparison operand specified by *imm*, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpge_epu64_mask

```
extern __mmask8 __cdecl _mm512_cmpge_epu64_mask(__m512i a, __m512i b);
```

Compare packed unsigned int64 elements in *a* and *b* for greater-than-or-equal, and store the results in mask vector *k*.

_mm512_mask_cmpge_epu64_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpge_epu64_mask(__mmask8 k, __m512i a, __m512i b);
```

Compare packed unsigned int64 elements in *a* and *b* for greater-than-or-equal, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpgt_epu64_mask

```
extern __mmask8 __cdecl _mm512_cmpgt_epu64_mask(__m512i a, __m512i b);
```

Compare packed unsigned int64 elements in *a* and *b* for greater-than, and store the results in mask vector *k*.

_mm512_mask_cmpgt_epu64_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpgt_epu64_mask(__mmask8 k, __m512i a, __m512i b);
```

Compare packed unsigned int64 elements in *a* and *b* for greater-than, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmple_epu64_mask

```
extern __mmask8 __cdecl _mm512_cmple_epu64_mask(__m512i a, __m512i b);
```

Compare packed unsigned int64 elements in *a* and *b* for less-than-or-equal, and store the results in mask vector *k*.

_mm512_mask_cmple_epu64_mask

```
extern __mmask8 __cdecl _mm512_mask_cmple_epu64_mask(__mmask8 k, __m512i a, __m512i b);
```

Compare packed unsigned int64 elements in *a* and *b* for less-than-or-equal, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmplt_epu64_mask

```
extern __mmask8 __cdecl _mm512_cmplt_epu64_mask(__m512i a, __m512i b);
```

Compare packed unsigned int64 elements in *a* and *b* for less-than, and store the results in mask vector *k*.

_mm512_mask_cmplt_epu64_mask

```
extern __mmask8 __cdecl _mm512_mask_cmplt_epu64_mask(__mmask8 k, __m512i a, __m512i b);
```

Compare packed unsigned int64 elements in *a* and *b* for less-than, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpeq_epu64_mask

```
extern __mmask8 __cdecl _mm512_cmpeq_epu64_mask(__m512i a, __m512i b);
```

Compare packed unsigned int64 elements in *a* and *b* for equality, and store the results in mask vector *k*.

_mm512_mask_cmpeq_epu64_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpeq_epu64_mask(__mmask8 k, __m512i a, __m512i b);
```

Compare packed unsigned int64 elements in *a* and *b* for equality, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cmpneq_epu64_mask

```
extern __mmask8 __cdecl _mm512_cmpneq_epu64_mask(__m512i a, __m512i b);
```

Compare packed unsigned int64 elements in *a* and *b* for not-equal, and store the results in mask vector *k*.

_mm512_mask_cmpneq_epu64_mask

```
extern __mmask8 __cdecl _mm512_mask_cmpneq_epu64_mask(__mmask8 k, __m512i a, __m512i b);
```

Compare packed unsigned int64 elements in *a* and *b* for not-equal, and store the results in mask vector *k* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Compression Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_mask_compress_pd`, `_mm512_maskz_compress_pd`	Contiguously store active float32 elements.	VCOMPRESSPD

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_mask_compress_ps`, `_mm512_maskz_compress_ps`	Contiguously store active float64 elements.	`VCOMPRESSPS`
`_mm512_mask_compress_epi32`, `_mm512_maskz_compress_epi32`, `_mm512_mask_compressstoreu_epi32`	Contiguously store active int32 elements.	`VPCOMPRESSD`
`_mm512_mask_compress_epi64`, `_mm512_maskz_compress_epi64`	Contiguously store active int64 elements.	`VPCOMPRESSQ`

variable	definition
k	writemask used as a selector
a	first source vector element
src	source element to use based on writemask result
base_addr	pointer to base address in memory to begin load or store operation

_mm512_mask_compress_pd

```
extern __m512d __cdecl _mm512_mask_compress_pd(__m512d a, __mmask8 k, __m512d src);
```

Contiguously stores the active float64 elements in *a* (those with their respective bit set in writemask *k*) to destination, and passes through the remaining elements from *src*.

_mm512_maskz_compress_pd

```
extern __m512d __cdecl _mm512_maskz_compress_pd(__mmask8 k, __m512d a);
```

Contiguously stores the active float64 elements in *a* (those with their respective bit set in zeromask *k*) to destination, and set the remaining elements to zero.

_mm512_mask_compress_ps

```
extern __m512 __cdecl _mm512_mask_compress_ps(__m512 a, __mmask16 k, __m512 src);
```

Contiguously stores the active float32 elements in *a* (those with their respective bit set in writemask *k*) to destination, and passes through the remaining elements from *src*.

_mm512_maskz_compress_ps

```
extern __m512 __cdecl _mm512_maskz_compress_ps(__mmask16 k, __m512 a);
```

Contiguously stores the active float32 elements in *a* (those with their respective bit set in zeromask *k*) to destination, and set the remaining elements to zero.

_mm512_mask_compressstoreu_pd

```
extern void __cdecl _mm512_mask_compressstoreu_pd(void* base_addr, __mmask8 k, __m512d a);
```

Contiguously stores the active float64 elements in *a* (those with their respective bit set in writemask *k*) to unaligned memory at *base_addr*.

_mm512_mask_compressstoreu_ps

```
extern void __cdecl _mm512_mask_compressstoreu_ps(void* base_addr, __mmask16 k, __m512 a);
```

Contiguously stores the active float32 elements in *a* (those with their respective bit set in writemask *k*) to unaligned memory at *base_addr*.

_mm512_mask_compress_epi32

```
extern __m512i __cdecl _mm512_mask_compress_epi32(__m512i a, __mmask16 k, __m512i src);
```

Contiguously stores the active int32 elements in *a* (those with their respective bit set in writemask *k*) to destination, and passes through the remaining elements from *src*.

_mm512_maskz_compress_epi32

```
extern __m512i __cdecl _mm512_maskz_compress_epi32(__mmask16 k, __m512i a);
```

Contiguously stores the active int32 elements in *a* (those with their respective bit set in zeromask *k*) to destination, and set the remaining elements to zero.

_mm512_mask_compress_epi64

```
extern __m512i __cdecl _mm512_mask_compress_epi64(__m512i a, __mmask8 k, __m512i src);
```

Contiguously stores the active int64 elements in *a* (those with their respective bit set in writemask *k*) to destination, and passes through the remaining elements from *src*.

_mm512_maskz_compress_epi64

```
extern __m512i __cdecl _mm512_maskz_compress_epi64(__mmask8 k, __m512i a);
```

Contiguously stores the active int64 elements in *a* (those with their respective bit set in zeromask *k*) to destination, and set the remaining elements to zero.

_mm512_mask_compressstoreu_epi32

```
extern void __cdecl _mm512_mask_compressstoreu_epi32(void* base_addr, __mmask16 k, __m512i a);
```

Contiguously stores the active int32 elements in *a* (those with their respective bit set in writemask *k*) to unaligned memory at *base_addr*.

_mm512_mask_compressstoreu_epi64

```
extern void __cdecl _mm512_mask_compressstoreu_epi64(void* base_addr, __mmask8 k, __m512i a);
```

Contiguously stores the active int64 elements in *a* (those with their respective bit set in writemask *k*) to unaligned memory at *base_addr*.

Intrinsics for Conversion Operations

Intrinsics for FP Conversion Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_cvtps_pd_mm512_mask_cvtps_pd_mm512_maskz_cvtps_pd _mm512_cvt_roundps_pd, _mm512_mask_cvt_roundps_pd, _mm512_maskz_cvt_roundps_pd	Converts rounded float32 to float 64.	VCVTPS2PD
_mm512_cvt_roundps_epi32, _mm512_mask_cvt_roundps_epi32, _mm512_maskz_cvt_roundps_epi32 _mm512_cvtt_roundps_epi32, _mm512_mask_cvtt_roundps_epi32, _mm512_maskz_cvtt_roundps_epi32	Converts rounded float32 to int32.	VCVTPS2DQ/VCVTTPS2DQ
_mm512_cvt_roundps_epu32, _mm512_mask_cvt_roundps_epu32, _mm512_maskz_cvt_roundps_epu32 _mm512_cvtt_roundps_epu32, _mm512_mask_cvtt_roundps_epu32, _mm512_maskz_cvtt_roundps_epu32	Converts rounded float32 to unsigned int32.	VCVTPS2UDQ/VCVTTPS2UDQ
_mm_cvt_roundsd_i32, _mm_cvt_roundsd_i64 _mm_cvtt_roundsd_i32, _mm_cvtt_roundsd_i64	Converts rounded scalar float64 to int32/int64.	VCVTSD2SI/VCVTTSD2SI
_mm_cvt_roundsd_u32, _mm_cvt_roundsd_u64 _mm_cvtt_roundsd_u32, _mm_cvtt_roundsd_u64	Converts rounded scalar float64 to unsigned int32/int64.	VCVTSD2USI/VCVTTSD2USI
_mm_cvt_roundss_i32, _mm_cvt_roundss_i64 _mm_cvtt_roundss_i32, _mm_cvtt_roundss_i64	Converts rounded scalar float32 to int32/int64.	VCVTSS2SI/VCVTTSS2SI

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm_cvt_roundss_u32, _mm_cvt_roundss_u64 _mm_cvtt_roundss_u32, _mm_cvtt_roundss_u64	Converts rounded scalar float32 to unsigned int32/int64.	VCVTSS2USI/VCVTTSS2USI

_mm512_cvt_roundps_ph, _mm512_mask_cvt_roundps_ph, _mm512_maskz_cvt_roundps_ph	Converts rounded float32 to scalar float32.	VCVTPS2PH
_mm_mask_cvtss_sd_mm_maskz_cvtss_sd _mm_cvt_roundss_sd, _mm_mask_cvt_roundss_sd, _mm_maskz_cvt_roundss_sd	Converts rounded scalar float32 to scalar float64.	VCVTSS2SD

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm_cvt_roundsd_ss`, `_mm_mask_cvt_roundsd_ss`, `_mm_maskz_cvt_roundsd_ss`	Converts rounded scalar float64 to scalar float32.	`VCVTSD2SS`
`_mm512_cvtepu32_ps_mm512_mask_cvtepu32_ps_mm512_maskz_cvtepu32_ps` `_mm512_cvt_roundepu32_ps_mm512_mask_cvt_roundepu32_ps_mm512_maskz_cvt_roundepu32_ps`	Converts packed unsigned int32 to float32.	`VCVTUDQ2PS`
`_mm512_cvtss_f32`	Extracts a float32 value from the first vector element of an `__m512`. It does so in the most efficient manner possible in the context used.	`MOVSS`/`VMOVSS`
`_mm512_cvtsd_f64`	Extracts a float64 value from first vector element of an `__m512d`. It does so in the most efficient manner possible in the context used.	`MOVSD`/`VMOVSD`

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result
round	Rounding control values; these can be one of the following (along with the `sae` suppress all exceptions flag): • `_MM_FROUND_TO_NEAREST_INT` - rounds to nearest even • `_MM_FROUND_TO_NEG_INF` - rounds to negative infinity • `_MM_FROUND_TO_POS_INF` - rounds to positive infinity • `_MM_FROUND_TO_ZERO` - rounds to zero • `_MM_FROUND_CUR_DIRECTION` - rounds using default from MXCSR register

_mm512_cvt_roundpd_ps

```
extern __m256 __cdecl _mm512_cvt_roundpd_ps(__m512d a, int round);
```

Converts float64 elements in *a* to float32 elements, and stores the result.

_mm512_mask_cvt_roundpd_ps

```
extern __m256 __cdecl _mm512_mask_cvt_roundpd_ps(__m256 src, __mmask8 k, __m512d a, int round);
```

Converts float64 elements in *a* to float32 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvt_roundpd_ps

```
extern __m256 __cdecl _mm512_maskz_cvt_roundpd_ps(__mmask8 k, __m512d a, int round);
```

Converts float64 elements in *a* to float32 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtpd_ps

```
extern __m256 __cdecl _mm512_cvt_pd_ps(__m512d a);
```

Converts float64 elements in *a* to float32 elements, and stores the result.

_mm512_mask_cvtpd_ps

```
extern __m256 __cdecl _mm512_mask_cvt_pd_ps(__m256 src, __mmask8 k, __m512d a);
```

Converts float64 elements in *a* to float32 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvtpd_ps

```
extern __m256 __cdecl _mm512_maskz_cvt_pd_ps(__mmask8 k, __m512d a);
```

Converts float64 elements in *a* to float32 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvt_roundpd_epi32

```
extern __m512i __cdecl _mm512_cvt_roundpd_epi32(__m512d a, int round);
```

Converts float64 elements in *a* to int32 elements, and stores the results.

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_mask_cvt_roundpd_epi32

```
extern __m512i __cdecl _mm512_mask_cvt_roundpd_epi32(__m256i src, __mmask8 k, __m512d a, int
round);
```

Converts float64 elements in *a* to int32 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_maskz_cvt_roundpd_epi32

```
extern __m512i __cdecl _mm512_maskz_cvt_roundpd_epi32(__mmask8 k, __m512d a, int round);
```

Converts float64 elements in *a* to int32 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

NOTE
Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_cvtpd_epi32

```
extern __m512i __cdecl _mm512_cvtpd_epi32(__m512d a);
```

Converts float64 elements in *a* int32 elements, and stores the result.

_mm512_mask_cvtpd_epi32

```
extern __m512i __cdecl _mm512_mask_cvtpd_epi32(__m256i src, __mmask8 k, __m512d a);
```

Converts float64 elements in *a* to int32 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvtpd_epi32

```
extern __m512i __cdecl _mm512_maskz_cvtpd_epi32(__mmask8 k, __m512d a);
```

Converts float64 elements in *a* to int32 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtt_roundpd_epi32

```
extern __m512i __cdecl _mm512_cvtt_roundpd_epi32(__m512d a, int round);
```

Converts float32 elements in *a* to int32 elements, and stores the results.

NOTE
Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_mask_cvtt_roundpd_epi32

```
extern __m512i __cdecl _mm512_mask_cvtt_roundpd_epi32(__m256i src, __mmask8 k, __m512d a, int
round);
```

Converts float32 elements in *a* to int32 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

NOTE
Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_maskz_cvtt_roundpd_epi32

```
extern __m512i __cdecl _mm512_maskz_cvtt_roundpd_epi32(__mmask8 k, __m512d a, int round);
```

Converts float32 elements in *a* to int32 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

NOTE
Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_cvttpd_epi32

```
extern __m512i __cdecl _mm512_cvttpd_epi32(__m512d a);
```

Converts float64 elements in *a* int32 elements, and stores the result.

_mm512_mask_cvttpd_epi32

```
extern __m512i __cdecl _mm512_mask_cvttpd_epi32(__m256i src, __mmask8 k, __m512d a);
```

Converts float64 elements in *a* to int32 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvttpd_epi32

```
extern __m512i __cdecl _mm512_maskz_cvttpd_epi32(__mmask8 k, __m512d a);
```

Converts float64 elements in *a* to int32 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvt_roundpd_epu32

```
extern __m512i __cdecl _mm512_cvt_roundpd_epu32(__m512 a, int round);
```

Converts float64 elements in *a* to int32 elements, and stores the results.

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_mask_cvt_roundpd_epu32

```
extern __m512i __cdecl _mm512_mask_cvt_roundpd_epu32(__m256i src, __mmask16 k, __m512 a, int
round);
```

Converts float64 elements in *a* to int32 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_maskz_cvt_roundpd_epu32

```
extern __m512i __cdecl _mm512_maskz_cvt_roundpd_epu32(__mmask16 k, __m512 a, int round);
```

Converts float64 elements in *a* to int32 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_cvtpd_epu32

```
extern __m512i __cdecl _mm512_cvtpd_epu32(__m512 a);

Converts float64 elements in *a* int32 elements, and stores the result.

_mm512_mask_cvtpd_epu32

```
extern __m512i __cdecl _mm512_mask_cvtpd_epu32(__m256i src, __mmask16 k, __m512 a);
```

Converts float64 elements in *a* to int32 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvtpd_epu32

```
extern __m512i __cdecl _mm512_maskz_cvtpd_epu32(__mmask16 k, __m512 a);
```

Converts float64 elements in *a* to int32 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtt_roundpd_epu32

```
extern __m512i __cdecl _mm512_cvtt_roundpd_epu32(__m512 a, int round);
```

Converts float64 elements in *a* to int32 elements, and stores the results.

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_mask_cvtt_roundpd_epu32

```
extern __m512i __cdecl _mm512_mask_cvtt_roundpd_epu32(__m256i src, __mmask16 k, __m512 a, int
round);
```

Converts float64 elements in *a* to int32 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_maskz_cvtt_roundpd_epu32

```
extern __m512i __cdecl _mm512_maskz_cvtt_roundpd_epu32(__mmask16 k, __m512 a, int round);
```

Converts float64 elements in *a* to int32 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_cvttpd_epu32

```
extern __m512i __cdecl _mm512_cvttpd_epu32(__m512 a);
```

Converts float64 elements in *a* int32 elements, and stores the result.

_mm512_mask_cvttpd_epu32

```
extern __m512i __cdecl _mm512_mask_cvttpd_epu32(__m256i src, __mmask16 k, __m512 a);
```

Converts float64 elements in *a* to int32 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvttpd_epu32

```
extern __m512i __cdecl _mm512_maskz_cvttpd_epu32(__mmask16 k, __m512 a);
```

Converts float64 elements in *a* to int32 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtph_ps

```
extern __m512 __cdecl _mm512_cvtph_ps(__m256i a);
```

Converts packed half-precision (16-bit) floating-point elements in *a* to float32 elements, and stores the results.

_mm512_mask_cvtph_ps

```
extern __m512 __cdecl _mm512_mask_cvtph_ps(__m512 src, __mmask16 k, __m256i a);
```

Converts packed half-precision (16-bit) floating-point elements in *a* to float32 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvtph_ps

```
extern __m512 __cdecl _mm512_maskz_cvtph_ps(__mmask16 k, __m256i a);
```

Converts packed half-precision (16-bit) floating-point elements in *a* to float32 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvt_roundph_ps

```
extern __m512 __cdecl _mm512_cvt_roundph_ps(__m256i a, int round);
```

Converts packed half-precision (16-bit) floating-point elements in *a* to float32 elements, and stores the result.

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_mask_cvt_roundph_ps

```
extern __m512 __cdecl _mm512_mask_cvt_roundph_ps(__m512 src, __mmask16 k, __m256i a, int round);
```

Converts packed half-precision (16-bit) floating-point elements in *a* to float32 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_maskz_cvt_roundph_ps

```
extern __m512 __cdecl _mm512_maskz_cvt_roundph_ps(__mmask16 k, __m256i a, int round);
```

Converts packed half-precision (16-bit) floating-point elements in *a* to float32 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

NOTE
Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_cvt_roundps_ph

```
extern __m256i __cdecl _mm512_cvt_roundps_ph(__m512 a, int round);
```

Converts float32 elements in *a* to packed half-precision (16-bit) floating-point elements, and stores the results.

NOTE
Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_mask_cvt_roundps_ph

```
extern __m256i __cdecl _mm512_mask_cvt_roundps_ph(__m256i src, __mmask16 k, __m512 a, int round);
```

Converts float32 elements in *a* to packed half-precision (16-bit) floating-point elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

NOTE
Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_maskz_cvt_roundps_ph

```
extern __m256i __cdecl _mm512_maskz_cvt_roundps_ph(__mmask16 k, __m512 a, int round);
```

Converts float32 elements in *a* to packed half-precision (16-bit) floating-point elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

NOTE
Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_cvtph_ps

```
extern __m256i __cdecl _mm512_cvtps_ph(__m512 a);
```

Converts packed half-precision (16-bit) floating-point elements in *a* to float32 elements, and stores the results.

_mm512_mask_cvtph_ps

```
extern __m256i __cdecl _mm512_mask_cvtps_ph(__m256i src, __mmask16 k, __m512 a);
```

Converts packed half-precision (16-bit) floating-point elements in *a* to float32 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvtph_ps

```
extern __m256i __cdecl _mm512_maskz_cvtps_ph(__mmask16 k, __m512 a);
```

Converts packed half-precision (16-bit) floating-point elements in *a* to float32 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvt_roundps_pd

```
extern __m512d __cdecl _mm512_cvt_roundps_pd(__m256 a, int round);
```

Converts float32 elements in *a* to float64 elements, and stores the results.

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_mask_cvt_roundps_pd

```
extern __m512d __cdecl _mm512_mask_cvt_roundps_pd(__m512d src, __mmask8 k, __m256 a, int round);
```

Converts float32 elements in *a* to float64 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_maskz_cvt_roundps_pd

```
extern __m512d __cdecl _mm512_maskz_cvt_roundps_pd(__mmask8 k, __m256 a, int round);
```

Converts float32 elements in *a* to float64 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Integer Conversion Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_cvtepi8_epi32`, `_mm512_mask_cvtepi8_epi32`, `_mm512_maskz_cvtepi8_epi32`	Up-converts int8 to int32.	`VPMOVSXBD`
`_mm512_cvtepi8_epi64`, `_mm512_mask_cvtepi8_epi64`, `_mm512_maskz_cvtepi8_epi64`	Up-converts int8 to int64.	`VPMOVSXBQ`
`_mm512_cvtepi16_epi32`, `_mm512_mask_cvtepi16_epi32`, `_mm512_maskz_cvtepi16_epi32`	Up-converts int16 to int32.	`VPMOVSXWD`
`_mm512_cvtepi16_epi64`, `_mm512_mask_cvtepi16_epi64`, `_mm512_maskz_cvtepi16_epi64`	Up-converts int16 to int64.	`VPMOVSXWQ`
`_mm512_cvtepi32_epi8`, `_mm512_mask_cvtepi32_epi8`, `_mm512_maskz_cvtepi32_epi8`	Down-converts int32 to int8.	`VPMOVDB`
`_mm512_cvtsepi32_epi8`, `_mm512_mask_cvtsepi32_epi8`, `_mm512_maskz_cvtsepi32_epi8`	Down-converts signed int32 to int8.	`VPMOVSDB`
`_mm512_cvtusepi32_epi8`, `_mm512_mask_cvtusepi32_epi8`, `_mm512_maskz_cvtusepi32_epi8`	Down-converts unsigned int32 to int8.	`VPMOVUSDB`
`_mm512_cvtepi32_epi16`, `_mm512_mask_cvtepi32_epi16`, `_mm512_maskz_cvtepi32_epi16`	Down-converts int32 to int16.	`VPMOVDW`
`_mm512_cvtsepi32_epi16`, `_mm512_mask_cvtsepi32_epi16`, `_mm512_maskz_cvtsepi32_epi16`	Down-converts signed int32 to int16.	`VPMOVSDW`
`_mm512_cvtusepi32_epi16`, `_mm512_mask_cvtusepi32_epi16`, `_mm512_maskz_cvtusepi32_epi16`	Down-converts unsigned int32 to int16.	`VPMOVUSDW`

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_cvtepi32_epi64, _mm512_mask_cvtepi32_epi64, _mm512_maskz_cvtepi32_epi64	Up-converts int32 to int64.	VPMOVSXDQ
_mm512_cvtepi64_epi8, _mm512_mask_cvtepi64_epi8, _mm512_maskz_cvtepi64_epi8	Down-converts int64 to int8.	VPMOVQB
_mm512_cvtsepi64_epi8, _mm512_mask_cvtsepi64_epi8, _mm512_maskz_cvtsepi64_epi8	Down-converts signed int64 to int8.	VPMOVSQB
_mm512_cvtusepi64_epi8, _mm512_mask_cvtusepi64_epi8, _mm512_maskz_cvtusepi64_epi8	Down-converts unsigned int64 to int8.	VPMOVUSQB
_mm512_cvtepi64_epi16, _mm512_mask_cvtepi64_epi16, _mm512_maskz_cvtepi64_epi16	Down-converts int64 to int16.	VPMOVQW
_mm512_cvtsepi64_epi16, _mm512_mask_cvtsepi64_epi16, _mm512_maskz_cvtsepi64_epi16	Down-converts signed int64 to int16.	VPMOVSQW
_mm512_cvtusepi64_epi16, _mm512_mask_cvtusepi64_epi16, _mm512_maskz_cvtusepi64_epi16	Down-converts unsigned int64 to int16.	VPMOVUSQW
_mm512_cvtepi64_epi32, _mm512_mask_cvtepi64_epi32, _mm512_maskz_cvtepi64_epi32	Down-converts int64 to int32.	VPMOVQD
_mm512_cvtsepi64_epi32, _mm512_mask_cvtsepi64_epi32, _mm512_maskz_cvtsepi64_epi32	Down-converts signed int64 to int32.	VPMOVSQD
_mm512_cvtusepi64_epi32, _mm512_mask_cvtusepi64_epi32, _mm512_maskz_cvtusepi64_epi32	Down-converts unsigned int64 to int32.	VPMOVUSQD
_mm512_cvtepu8_epi64, _mm512_mask_cvtepu8_epi64, _mm512_maskz_cvtepu8_epi64	Up-converts unsigned int8 to int64.	VPMOVZXBQ
_mm512_cvtepu16_epi32, _mm512_mask_cvtepu16_epi32, _mm512_maskz_cvtepu16_epi32	Up-converts unsigned int16 to int32.	VPMOVZXWD
_mm512_cvtepu32_epi64, _mm512_mask_cvtepu32_epi64, _mm512_maskz_cvtepu32_epi64	Up-converts unsigned int32 to int64.	VPMOVZXDQ

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_cvtepi32_pd, _mm512_mask_cvtepi32_pd, _mm512_maskz_cvtepi32_pd	Converts int32 to float64.	VCVTDQ2PD
_mm512_cvt_roundepi32_ps, _mm512_mask_cvt_roundepi32_ps, _mm512_maskz_cvt_roundepi32_ps	Converts int32 to float32.	VCVTDQ2PS
_mm512_cvt_roundepu32_ps, _mm512_mask_cvt_roundepu32_ps, _mm512_maskz_cvt_roundepu32_ps	Converts unsigned int32 to float32.	VCVTUDQ2PS
_mm512_cvtepu32_pd, _mm512_mask_cvtepu32_pd, _mm512_maskz_cvtepu32_pd	Converts unsigned int32 to float64.	VCVTUQD2PD
_mm_cvtu32_sd	Converts unsigned int32 to scalar float64.	VCVTUSI2SD
_mm_cvt_roundi64_sd, _mm_cvt_roundu64_sd	Converts rounded int64 to scalar float64.	VCVTSI2SD
_mm_cvt_roundi32_ss, _mm_cvt_roundi64_ss	Converts unsigned int32 to scalar float32.	VCVTSI2SS
_mm_cvt_roundu32_ss, _mm_cvt_roundu64_ss	Converts rounded int64 to scalar float32.	VCVTUSI2SS
_mm512_cvtsi512_si32	Moves the least significant vector element to a scalar 32-bit integer.	MOVD/VMOVD

variable	definition
k	zeromask used as a selector
k	writemask used as a selector
a	first source vector element
b	second source vector element
c	third source vector element
round	Rounding control values; these can be one of the following (along with the sae suppress all exceptions flag): • _MM_FROUND_TO_NEAREST_INT - rounds to nearest even • _MM_FROUND_TO_NEG_INF - rounds to negative infinity • _MM_FROUND_TO_POS_INF - rounds to positive infinity • _MM_FROUND_TO_ZERO - rounds to zero • _MM_FROUND_CUR_DIRECTION - rounds using default from MXCSR register

src	source element

_mm512_cvt_roundpd_epi32

```
extern __m256i __cdecl _mm512_cvt_roundpd_epi32(__m512d a, int round);
```

Converts packed float64 elements in *a* to packed 32-bit integers, and stores the result.

_mm512_cvtpd_epi32

```
extern __m256i __cdecl _mm512_cvtpd_epi32(__m512d a);
```

Converts packed float64 elements in *a* to packed 32-bit integers, and stores the result.

_mm512_mask_cvt_roundpd_epi32

```
extern __m256i __cdecl _mm512_mask_cvt_roundpd_epi32(__m256i src, __mmask8 k, __m512d a, int
round);
```

Converts packed float64 elements in *a* to packed 32-bit integers, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_mask_cvtpd_epi32

```
extern __m256i __cdecl _mm512_mask_cvtpd_epi32(__m256i src, __mmask8 k, __m512d a);
```

Converts packed float64 elements in *a* to packed 32-bit integers, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvt_roundpd_epi32

```
extern __m256i __cdecl _mm512_maskz_cvt_roundpd_epi32(__mmask8 k, __m512d a, int round);
```

Converts packed float64 elements in *a* to packed 32-bit integers, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_maskz_cvtpd_epi32

```
extern __m256i __cdecl _mm512_maskz_cvtpd_epi32(__mmask8 k, __m512d a);
```

Converts packed float64 elements in *a* to packed 32-bit integers, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvt_roundpd_epu32

```
extern __m256i __cdecl _mm512_cvt_roundpd_epu32(__m512d a, int round);
```

Converts packed float64 elements in *a* to packed unsigned 32-bit integers, and stores the result.

_mm512_cvtpd_epu32

```
extern __m256i __cdecl _mm512_cvtpd_epu32(__m512d a);
```

Converts packed float64 elements in *a* to packed unsigned 32-bit integers, and stores the result.

_mm512_mask_cvt_roundpd_epu32

```
extern __m256i __cdecl _mm512_mask_cvt_roundpd_epu32(__m256i src, __mmask8 k, __m512d a, int round);
```

Converts packed float64 elements in *a* to packed unsigned 32-bit integers, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_mask_cvtpd_epu32

```
extern __m256i __cdecl _mm512_mask_cvtpd_epu32(__m256i src, __mmask8 k, __m512d a);
```

Converts packed float64 elements in *a* to packed unsigned 32-bit integers, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvt_roundpd_epu32

```
extern __m256i __cdecl _mm512_maskz_cvt_roundpd_epu32(__mmask8 k, __m512d a, int round);
```

Converts packed float64 elements in *a* to packed unsigned 32-bit integers, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_maskz_cvtpd_epu32

```
extern __m256i __cdecl _mm512_maskz_cvtpd_epu32(__mmask8 k, __m512d a);
```

Converts packed float64 elements in *a* to packed unsigned 32-bit integers, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvt_roundps_epi32

```
extern __m512i __cdecl _mm512_cvt_roundps_epi32(__m512 a, int round);
```

Converts packed float32 elements in *a* to packed 32-bit integers, and stores the result.

_mm512_cvtps_epi32

```
extern __m512i __cdecl _mm512_cvtps_epi32(__m512 a);
```

Converts packed float32 elements in *a* to packed 32-bit integers, and stores the result.

_mm512_mask_cvt_roundps_epi32

```
extern __m512i __cdecl _mm512_mask_cvt_roundps_epi32(__m512i src, __mmask16 k, __m512 a, int round);
```

Converts packed float32 elements in *a* to packed 32-bit integers, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_mask_cvtps_epi32

```
extern __m512i __cdecl _mm512_mask_cvtps_epi32(__m512i src, __mmask16 k, __m512 a);
```

Converts packed float32 elements in *a* to packed 32-bit integers, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvt_roundps_epi32

```
extern __m512i __cdecl _mm512_maskz_cvt_roundps_epi32(__mmask16 k, __m512 a, int round);
```

Converts packed float32 elements in *a* to packed 32-bit integers, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_maskz_cvtps_epi32

```
extern __m512i __cdecl _mm512_maskz_cvtps_epi32(__mmask16 k, __m512 a);
```

Converts packed float32 elements in *a* to packed 32-bit integers, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvt_roundps_ph

```
extern __m256i __cdecl _mm512_cvt_roundps_ph(__m512 a, int round);
```

Converts packed float32 elements in *a* to packed half-precision (16-bit) floating-point elements, and stores the result.

_mm512_cvtps_ph

```
extern __m256i __cdecl _mm512_cvtps_ph(__m512 a, int round);
```

Converts packed float32 elements in *a* to packed half-precision (16-bit) floating-point elements, and stores the result.

_mm512_mask_cvt_roundps_ph

```
extern __m256i __cdecl _mm512_mask_cvt_roundps_ph(__m256i src, __mmask16 k, __m512 a, int
round);
```

Converts packed float32 elements in *a* to packed half-precision (16-bit) floating-point elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_mask_cvtps_ph

```
extern __m256i __cdecl _mm512_mask_cvtps_ph(__m256i src, __mmask16 k, __m512 a, int round);
```

Converts packed float32 elements in *a* to packed half-precision (16-bit) floating-point elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvt_roundps_ph

```
extern __m256i __cdecl _mm512_maskz_cvt_roundps_ph(__mmask16 k, __m512 a, int round);
```

Converts packed float32 elements in *a* to packed half-precision (16-bit) floating-point elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_maskz_cvtps_ph

```
extern __m256i __cdecl _mm512_maskz_cvtps_ph(__mmask16 k, __m512 a, int round);
```

Converts packed float32 elements in *a* to packed half-precision (16-bit) floating-point elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvt_roundps_epu32

```
extern __m512i __cdecl _mm512_cvt_roundps_epu32(__m512 a, int round);
```

Converts packed float32 elements in *a* to packed unsigned 32-bit integers, and stores the result.

_mm512_cvtps_epu32

```
extern __m512i __cdecl _mm512_cvtps_epu32(__m512 a);
```

Converts packed float32 elements in *a* to packed unsigned 32-bit integers, and stores the result.

_mm512_mask_cvt_roundps_epu32

```
extern __m512i __cdecl _mm512_mask_cvt_roundps_epu32(__m512i src, __mmask16 k, __m512 a, int round);
```

Converts packed float32 elements in *a* to packed unsigned 32-bit integers, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_mask_cvtps_epu32

```
extern __m512i __cdecl _mm512_mask_cvtps_epu32(__m512i src, __mmask16 k, __m512 a);
```

Converts packed float32 elements in *a* to packed unsigned 32-bit integers, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvt_roundps_epu32

```
extern __m512i __cdecl _mm512_maskz_cvt_roundps_epu32(__mmask16 k, __m512 a, int round);
```

Converts packed float32 elements in *a* to packed unsigned 32-bit integers, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_maskz_cvtps_epu32

```
extern __m512i __cdecl _mm512_maskz_cvtps_epu32(__mmask16 k, __m512 a);
```

Converts packed float32 elements in *a* to packed unsigned 32-bit integers, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm_cvt_roundsd_i32

```
extern int __cdecl _mm_cvt_roundsd_i32(__m128d, int);
```

Convert the lower float64 element in *a* to a 32-bit integer, and stores the result.

_mm_cvt_roundsd_i64

```
extern __int64 __cdecl _mm_cvt_roundsd_i64(__m128d, int);
```

Convert the lower float64 element in *a* to a 64-bit integer, and stores the result.

_mm_cvt_roundsd_si32

```
extern int __cdecl _mm_cvt_roundsd_i32(__m128d, int);
```

Convert the lower float64 element in *a* to a 32-bit integer, and stores the result.

_mm_cvt_roundsd_si64

```
extern __int64 __cdecl _mm_cvt_roundsd_i64(__m128d, int);
```

Convert the lower float64 element in *a* to a 64-bit integer, and stores the result.

_mm_cvtsd_i32

```
extern int __cdecl _mm_cvtsd_i32(__m128d, int);
```

Convert the lower float64 element in *a* to a 32-bit integer, and stores the result.

_mm_cvtsd_i64

```
extern __int64 __cdecl _mm_cvtsd_i64(__m128d, int);
```

Convert the lower float64 element in *a* to a 64-bit integer, and stores the result.

_mm_cvt_roundsd_ss

```
extern __m128 __cdecl _mm_cvtsd_ss(__m128 a, __m128d b, int round);
```

Convert the lower float64 element in *b* to a float32 element, and stores the result in the lower destination element, and copies the upper three packed elements from *a* to the upper destination elements.

_mm_mask_cvt_roundsd_ss

```
extern __m128 __cdecl _mm_mask_cvt_roundsd_ss(__m128 src, __mmask8 k, __m128 a, __m128d b,
int round);
```

Convert the lower float64 element in *b* to a float32 element, and stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper element from *a* to the upper destination element.

_mm_mask_cvtsd_ss

```
extern __m128 __cdecl _mm_mask_cvtsd_ss(__m128 src, __mmask8 k, __m128 a, __m128d b, int
round);
```

Convert the lower float64 element in *b* to a float32 element, and stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper element from *a* to the upper destination element.

_mm_maskz_cvt_roundsd_ss

```
extern __m128 __cdecl _mm_maskz_cvt_roundsd_ss(__mmask8 k, __m128 a, __m128d b, int round);
```

Convert the lower float64 element in *b* to a float32 element, and stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from *a* to the upper destination elements.

_mm_maskz_cvtsd_ss

```
extern __m128 __cdecl _mm_maskz_cvtsd_ss(__mmask8 k, __m128 a, __m128d b, int round);
```

Convert the lower float64 element in *b* to a float32 element, and stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from *a* to the upper destination elements.

_mm_cvt_roundsd_u32

```
extern unsigned int __cdecl _mm_cvt_roundsd_u32(__m128d a, int round);
```

Convert the lower float64 element in *a* to an unsigned 32-bit integer, and stores the result.

_mm_cvt_roundsd_u64

```
extern unsigned __int64 __cdecl _mm_cvt_roundsd_u64(__m128d a, int round);
```

Convert the lower float64 element in *a* to an unsigned 64-bit integer, and stores the result.

_mm_cvtsd_u32

```
extern unsigned int __cdecl _mm_cvtsd_u32(__m128d a);
```

Convert the lower float64 element in *a* to an unsigned 32-bit integer, and stores the result.

_mm_cvtsd_u64

```
extern unsigned __int64 __cdecl _mm_cvtsd_u64(__m128d a);
```

Convert the lower float64 element in *a* to an unsigned 64-bit integer, and stores the result.

_mm_cvt_roundss_i32

```
extern int __cdecl _mm_cvt_roundss_i32(__m128 a, int round);
```

Convert the lower float32 element in *a* to a 32-bit integer, and stores the result.

_mm_cvt_roundss_i64

```
extern __int64 __cdecl _mm_cvt_roundss_i64(__m128 a, int round);
```

Convert the lower float32 element in *a* to a 64-bit integer, and stores the result.

_mm_cvt_roundss_si32

```
extern int __cdecl _mm_cvt_roundss_si32(__m128 a, int round);
```

Convert the lower float32 element in *a* to a 32-bit integer, and stores the result.

```
extern __int64 __cdecl _mm_cvt_roundss_si64(__m128 a, int round);
```

Convert the lower float32 element in *a* to a 64-bit integer, and stores the result.

_mm_cvtss_i32

```
extern
```

Convert the lower float32 element in *a* to a 32-bit integer, and stores the result.

_mm_cvtss_i64

```
extern
```

Convert the lower float32 element in *a* to a 64-bit integer, and stores the result.

_mm_cvt_roundss_u32

```
extern unsigned int __cdecl _mm_cvt_roundss_u32(__m128 a, int round);
```

Convert the lower float32 element in *a* to an unsigned 32-bit integer, and stores the result.

_mm_cvt_roundss_u64

```
extern unsigned __int64 __cdecl _mm_cvt_roundss_u64(__m128 a, int round);
```

Convert the lower float32 element in *a* to an unsigned 64-bit integer, and stores the result.

_mm_cvtss_u32

```
extern unsigned int __cdecl _mm_cvtss_u32(__m128 a);
```

Convert the lower float32 element in *a* to an unsigned 32-bit integer, and stores the result.

_mm_cvtss_u64

```
extern unsigned __int64 __cdecl _mm_cvtss_u64(__m128 a);
```

Convert the lower float32 element in *a* to an unsigned 64-bit integer, and stores the result.

_mm512_cvtt_roundpd_epi32

```
extern __m256i __cdecl _mm512_cvtt_roundpd_epi32(__m512d a, int round);
```

Converts packed float64 elements in *a* to packed int32 elements with truncation, and stores the result.

> **NOTE**
> Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_cvttpd_epi32

```
extern __m256i __cdecl _mm512_cvttpd_epi32(__m512d a);
```

Converts packed float64 elements in *a* to packed int32 elements with truncation, and stores the result in *dst*.

_mm512_mask_cvtt_roundpd_epi32

```
extern __m256i __cdecl _mm512_mask_cvtt_roundpd_epi32(__m256i src, __mmask8 k, __m512d a,
int round);
```

Converts packed float64 elements in *a* to packed int32 elements with truncation, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

NOTE
Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_mask_cvttpd_epi32

```
extern __m256i __cdecl _mm512_mask_cvttpd_epi32(__m256i src, __mmask8 k, __m512d a, int round);
```

Converts packed float64 elements in *a* to packed int32 elements with truncation, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvtt_roundpd_epi32

```
extern __m256i __cdecl _mm512_maskz_cvtt_roundpd_epi32(__mmask8 k, __m512d a, int round);
```

Converts packed float64 elements in *a* to packed int32 elements with truncation, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

NOTE
Pass `__MM_FROUND_NO_EXC` to *sae* to suppress all exceptions.

_mm512_cvtepi64_epi16

```
extern __m128i __cdecl _mm512_cvtepi64_epi16(__m512i a);
```

Converts packed int64 elements in *a* to packed 16-bit integers with truncation, and stores the result.

_mm512_mask_cvtepi64_epi16

```
extern __m128i __cdecl _mm512_mask_cvtepi64_epi16(__m128i src, __mmask8 k, __m512i a);
```

Converts packed int64 elements in *a* to packed 16-bit integers with truncation, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_mask_cvtepi64_storeu_epi16

```
extern void __cdecl _mm512_mask_cvtepi64_storeu_epi16(void* base_addr, __mmask8 k, __m512i a);
```

Converts packed int64 elements in *a* to packed 16-bit integers with truncation, and store the active results (those with their respective bit set in writemask *k*) to unaligned memory at *base_addr*.

_mm512_maskz_cvtepi64_epi16

```
extern __m128i __cdecl _mm512_maskz_cvtepi64_epi16(__mmask8 k, __m512i a);
```

Converts packed int64 elements in *a* to packed 16-bit integers with truncation, and stores the result in *dst* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtsepi32_epi8

```
extern __m128i __cdecl _mm512_cvtsepi32_epi8(__m512i a);
```

Converts packed int32 elements in *a* to packed 8-bit integers with signed saturation, and stores the result.

_mm512_mask_cvtsepi32_epi8

```
extern __m128i __cdecl _mm512_mask_cvtsepi32_epi8(__m128i src, __mmask16 k, __m512i a);
```

Converts packed int32 elements in *a* to packed 8-bit integers with signed saturation, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_mask_cvtsepi32_storeu_epi8

```
extern void __cdecl _mm512_mask_cvtsepi32_storeu_epi8(void* base_addr, __mmask16 k, __m512i a);
```

Converts packed int32 elements in *a* to packed 8-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask *k*) to unaligned memory at *base_addr*.

_mm512_maskz_cvtsepi32_epi8

```
extern __m128i __cdecl _mm512_maskz_cvtsepi32_epi8(__mmask16 k, __m512i a);
```

Converts packed int32 elements in *a* to packed 8-bit integers with signed saturation, and stores the result in *dst* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtsepi32_epi16

```
extern __m256i __cdecl _mm512_cvtsepi32_epi16(__m512i a);
```

Converts packed int32 elements in *a* to packed 16-bit integers with signed saturation, and stores the result.

_mm512_mask_cvtsepi32_epi16

```
extern __m256i __cdecl _mm512_mask_cvtsepi32_epi16(__m256i src, __mmask16 k, __m512i a);
```

Converts packed int32 elements in *a* to packed 16-bit integers with signed saturation, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_mask_cvtsepi32_storeu_epi16

```
    extern void __cdecl _mm512_mask_cvtsepi32_storeu_epi16(void* base_addr, __mmask16 k,
__m512i a);
```

Converts packed int32 elements in *a* to packed 16-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask *k*) to unaligned memory at *base_addr*.

_mm512_maskz_cvtsepi32_epi16

```
    extern __m256i __cdecl _mm512_maskz_cvtsepi32_epi16(__mmask16 k, __m512i a);
```

Converts packed int32 elements in *a* to packed 16-bit integers with signed saturation, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtsepi64_epi8

```
    extern __m128i __cdecl _mm512_cvtsepi64_epi8(__m512i a);
```

Converts packed int64 elements in *a* to packed 8-bit integers with signed saturation, and stores the result.

_mm512_mask_cvtsepi64_epi8

```
    extern __m128i __cdecl _mm512_mask_cvtsepi64_epi8(__m128i src, __mmask8 k, __m512i a);
```

Converts packed int64 elements in *a* to packed 8-bit integers with signed saturation, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_mask_cvtsepi64_storeu_epi8

```
    extern void __cdecl _mm512_mask_cvtsepi64_storeu_epi8(void* base_addr, __mmask8 k, __m512i
a);
```

Converts packed int64 elements in *a* to packed 8-bit integers with signed saturation, and store the active results (those with their respective bit set in writemask *k*) to unaligned memory at *base_addr*.

_mm512_maskz_cvtsepi64_epi8

```
    extern __m128i __cdecl _mm512_maskz_cvtsepi64_epi8(__mmask8 k, __m512i a);
```

Converts packed int64 elements in *a* to packed 8-bit integers with signed saturation, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtsepi64_epi32

```
    extern __m256i __cdecl _mm512_cvtsepi64_epi32(__m512i a);
```

Converts packed int64 elements in *a* to packed int32 elements with signed saturation, and stores the result.

_mm512_mask_cvtsepi64_epi32

```
    extern __m256i __cdecl _mm512_mask_cvtsepi64_epi32(__m256i src, __mmask8 k, __m512i a);
```

Converts packed int64 elements in *a* to packed int32 elements with signed saturation, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_mask_cvtsepi64_storeu_epi32

```
extern void __cdecl _mm512_mask_cvtsepi64_storeu_epi32(void* base_addr, __mmask8 k, __m512i a);
```

Converts packed int64 elements in *a* to packed int32 elements with signed saturation, and store the active results (those with their respective bit set in writemask *k*) to unaligned memory at *base_addr*.

_mm512_maskz_cvtsepi64_epi32

```
extern __m256i __cdecl _mm512_maskz_cvtsepi64_epi32(__mmask8 k, __m512i a);
```

Converts packed int64 elements in *a* to packed int32 elements with signed saturation, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtsepi64_epi16

```
extern __m128i __cdecl _mm512_cvtsepi64_epi16(__m512i a);
```

Converts packed int64 elements in *a* to packed 16-bit integers with signed saturation, and stores the result.

_mm512_mask_cvtsepi64_epi16

```
extern __m128i __cdecl _mm512_mask_cvtsepi64_epi16(__m128i src, __mmask8 k, __m512i a);
```

Converts packed int64 elements in *a* to packed 16-bit integers with signed saturation, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_mask_cvtsepi64_storeu_epi16

```
extern void __cdecl _mm512_mask_cvtsepi64_storeu_epi16(void* base_addr, __mmask8 k, __m512i a);
```

Converts packed int64 elements in *a* to packed 16-bit integers with signed saturation, and stores the active results (those with their respective bit set in writemask *k*) to unaligned memory at *base_addr*.

_mm512_maskz_cvtsepi64_epi16

```
extern __m128i __cdecl _mm512_maskz_cvtsepi64_epi16(__mmask8 k, __m512i a);
```

Converts packed int64 elements in *a* to packed 16-bit integers with signed saturation, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtepi8_epi32

```
extern __m512i __cdecl _mm512_cvtepi8_epi32(__m128i a);
```

Sign extend packed 8-bit integers in *a* to packed 32-bit integers, and stores the result.

_mm512_mask_cvtepi8_epi32

```
extern __m512i __cdecl _mm512_mask_cvtepi8_epi32(__m512i src, __mmask16 k, __m128i a);
```

Sign extend packed 8-bit integers in *a* to packed 32-bit integers, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvtepi8_epi32

```
extern __m512i __cdecl _mm512_maskz_cvtepi8_epi32(__mmask16 k, __m128i a);

Zero extend packed unsigned 16-bit integers in *a* to packed 32-bit integers, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtepu16_epi64

```
extern __m512i __cdecl _mm512_cvtepu16_epi64(__m128i a);
```

Zero extend packed unsigned 16-bit integers in *a* to packed int64 elements, and stores the result.

_mm512_mask_cvtepu16_epi64

```
extern __m512i __cdecl _mm512_mask_cvtepu16_epi64(__m512i src, __mmask8 k, __m128i a);
```

Zero extend packed unsigned 16-bit integers in *a* to packed int64 elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_cvtepu16_epi64

```
extern __m512i __cdecl _mm512_maskz_cvtepu16_epi64(__mmask8 k, __m128i a);
```

Zero extend packed unsigned 16-bit integers in *a* to packed int64 elements, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_cvtsi512_si32

```
int _mm512_cvtsi512_si32(__m512i a);
```

Moves the least significant 32 bits of *a* to a 32-bit integer.

Intrinsics for Expand and Load Operations

Intrinsics for FP Expand and Load Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_expand_pd`, `_mm512_mask_expand_pd`, `_mm512_maskz_expand_pd`	Load packed float64 values from dense memory.	`VEXPANDPD`
`_mm512_mask_expandloadu_pd`, `_mm512_maskz_expandloadu_pd`	Load packed float64 values from dense memory.	`VEXPANDPD`
`_mm512_expand_ps`, `_mm512_mask_expand_ps`, `_mm512_maskz_expand_ps`	Load packed float32 values from dense memory.	`VEXPANDPS`
`_mm512_mask_expandloadu_ps`, `_mm512_maskz_expandloadu_ps`	Load packed float32 values from dense memory.	`VEXPANDPS`

variable	definition
k	writemask used as a selector

variable	definition
a	first source vector element
src	source element to use based on writemask result
mem_addr	pointer to memory address

_mm512_expand_pd

```
extern __m512d __cdecl _mm512_expand_pd(__m512d a);
```

Loads contiguous active float64 elements from *a* (those with their respective bit set in mask *k*), and stores the result.

_mm512_mask_expand_pd

```
extern __m512d __cdecl _mm512_mask_expand_pd(__m512d src, __mmask8 k, __m512d a);
```

Loads contiguous active float64 elements from *a* (those with their respective bit set in mask *k*), and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_expand_pd

```
extern __m512d __cdecl _mm512_maskz_expand_pd(__mmask8 k, __m512d a);
```

Loads contiguous active float64 elements from *a* (those with their respective bit set in mask *k*), and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_expand_ps

```
extern __m512 __cdecl _mm512_expand_ps(__m512 a);
```

Loads contiguous active float32 elements from *a* (those with their respective bit set in mask *k*), and stores the result.

_mm512_mask_expand_ps

```
extern __m512 __cdecl _mm512_mask_expand_ps(__m512 src, __mmask16 k, __m512 a);
```

Loads contiguous active float32 elements from *a* (those with their respective bit set in mask *k*), and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_expand_ps

```
extern __m512 __cdecl _mm512_maskz_expand_ps(__mmask16 k, __m512 a);
```

Loads contiguous active float32 elements from *a* (those with their respective bit set in mask *k*), and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mask_expandloadu_pd

```
extern __m512d __cdecl _mm512_mask_expandloadu_pd(__m512d src, __mmask8 k, void * mem_addr);
```

Loads contiguous active float64 elements from unaligned memory at *mem_addr* (those with their respective bit set in mask *k*), and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_expandloadu_pd

```
extern __m512d __cdecl _mm512_maskz_expandloadu_pd(__mmask8 k, void * mem_addr);
```

Loads contiguous active float64 elements from unaligned memory at *mem_addr* (those with their respective bit set in mask *k*), and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mask_expandloadu_ps

```
extern __m512 __cdecl _mm512_mask_expandloadu_ps(__m512 src, __mmask16 k, void * mem_addr);
```

Loads contiguous active float32 elements from unaligned memory at *mem_addr* (those with their respective bit set in mask *k*), and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_expandloadu_ps

```
extern __m512 __cdecl _mm512_maskz_expandloadu_ps(__mmask16 k, void * mem_addr);
```

Loads contiguous active float32 elements from unaligned memory at *mem_addr* (those with their respective bit set in mask *k*), and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Integer Expand and Load Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_mask_expandloadu_epi32`, `_mm512_maskz_expandloadu_epi32` `_mm512_mask_expand_epi32`, `_mm512_maskz_expand_epi32`	Load packed int32 values from dense memory or register.	`VPEXPANDD`
`_mm512_mask_expandloadu_epi64`, `_mm512_maskz_expandloadu_epi64` `_mm512_mask_expand_epi64`, `_mm512_maskz_expand_epi64`	Load packed int64 values from dense memory or register.	`VPEXPANDQ`

variable	definition
k	writemask used as a selector
a	first source vector element
src	source element to use based on writemask result
mem_addr	pointer to base address in memory

_mm512_mask_expand_epi32

```
extern __m512i __cdecl _mm512_mask_expand_epi32(__m512i src, __mmask16 k, __m512i a);
```

Loads contiguous active int32 elements from *a* (those with their respective bit set in mask *k*), and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_expand_epi32

```
extern __m512i __cdecl _mm512_maskz_expand_epi32(__mmask16 k, __m512i a);
```

Loads contiguous active int32 elements from *a* (those with their respective bit set in mask *k*), and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mask_expandloadu_epi32

```
extern __m512i __cdecl _mm512_mask_expandloadu_epi32(__m512i src, __mmask16 k, void * mem_addr);
```

Loads contiguous active int32 elements from unaligned memory at *mem_addr* (those with their respective bit set in mask *k*), and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_expandloadu_epi32

```
extern __m512i __cdecl _mm512_maskz_expandloadu_epi32( __mmask16 k, void * mem_addr);
```

Loads contiguous active int32 elements from unaligned memory at *mem_addr* (those with their respective bit set in mask *k*), and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mask_expandloadu_epi64

```
extern __m512i __cdecl _mm512_mask_expandloadu_epi64(__m512i src, __mmask8 k, void * mem_addr);
```

Loads contiguous active int64 elements from unaligned memory at *mem_addr* (those with their respective bit set in mask *k*), and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_expandloadu_epi64

```
extern __m512i __cdecl _mm512_maskz_expandloadu_epi64(__mmask8 k, void * mem_addr);
```

Loads contiguous active int64 elements from unaligned memory at *mem_addr* (those with their respective bit set in mask *k*), and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mask_expand_epi64

```
extern __m512i __cdecl _mm512_mask_expand_epi64(__m512i src, __mmask8 k, __m512i a);
```

Loads contiguous active int64 elements from *a* (those with their respective bit set in mask *k*), and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_expand_epi64

```
extern __m512i __cdecl _mm512_maskz_expand_epi64(__mmask8 k, __m512i a);
```

Loads contiguous active int64 elements from *a* (those with their respective bit set in mask *k*), and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Gather and Scatter Operations

Intrinsics for FP Gather and Scatter Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_i32gather_pd`, `_mm512_mask_i32gather_pd`	Gathers double-precision (64-bit) floating-point elements from memory with 32-bit integer indices.	`VGATHERDPD`
`_mm512_i32gather_ps`, `_mm512_mask_i32gather_ps`	Gathers single-precision (32-bit) vector elements from memory with 32-bit integer indices.	`VGATHERDPS`
`_mm512_i32extgather_ps`, `_mm512_mask_i32extgather_ps`	Up-converts single-precision (32-bit) floating-point elements from memory with 32-bit integer indices.	`VGATHERDPS`
`_mm512_i64gather_pd`, `_mm512_mask_i64gather_pd`	Gathers double-precision (64-bit) floating-point elements from memory with 64-bit integer indices.	`VGATHERQPD`
`_mm512_i64gather_ps`, `_mm512_mask_i64gather_ps`	Gathers single-precision (32-bit) vector elements from memory with 64-bit integer indices.	`VGATHERQPS`
`_mm512_prefetch_i32gather_pd`, `_mm512_mask_prefetch_i32gather_pd`	Gathers prefetch double-precision (64-bit) floating-point elements with 32-bit integer indices.	`VGATHERPF0DPD`, `VGATHERPF1DPD`
`_mm512_prefetch_i32gather_ps`, `_mm512_mask_prefetch_i32gather_ps`	Gathers prefetch double-precision (64-bit) floating-point elements with 32-bit integer indices.	`VGATHERPF0DPS`, `VGATHERPF1DPS`

`_mm512_prefetch_i64scatter_ps`, `_mm512_mask_prefetch_i64scatter_ps`	Scatters prefetch double-precision (64-bit) floating-point elements with 64-bit integer indices.	`VSCATTERPF0QPS`, `VSCATTERPF1QPS`

variable	definition
vindex	a vector of indices
base_addr	a pointer to the base address in memory
scale	a compilation-time literal constant that is used as the vector indices scale. Possible values are 1, 2, 4, or 8.
k	mask used as a selector
a	first source vector element
src	source element to use based on the mask result
upconv	Where _MM_UPCONV_PS_ENUM is the following:

variable	definition
	• _MM_UPCONV_PS_NONE - no conversion
index	a vector containing indexes in memory *mv*
downconv	Where _MM_DOWNCONV_PS_ENUM is the following: • _MM_DOWNCONV_PS_NONE - no conversion
hint	Indicates which cache level to bring values into. _MM_HINT_ENUM is the following: • _MM_HINT_NONE 0x0 - Off

_mm512_i32gather_pd

```
__m512d _mm512_i32gather_pd (__m256i vindex, void const* base_addr, int scale)
```

Gather double-precision (64-bit) floating-point elements from memory using 32-bit indices. 64-bit elements are loaded from addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i32gather_pd

```
__m512d _mm512_mask_i32gather_pd (__m512d src, __mmask8 k, __m256i vindex, void const*
base_addr, int scale)
```

Gathers double-precision (64-bit) floating-point elements from memory using 32-bit indices. 64-bit elements are loaded from addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*). Gathered elements are merged with *src* using mask *k*. When the corresponding mask bit is not set, elements are copied from *src*.

_mm512_i32gather_ps

```
__m512 _mm512_i32gather_ps (__m512i vindex, void const* base_addr, int scale)
```

Gathers single-precision (32-bit) floating-point elements from memory using 32-bit indices. 32-bit elements are loaded from addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i32gather_ps

```
__m512 _mm512_mask_i32gather_ps (__m512 src, __mmask16 k, __m512i vindex, void const* base_addr,
int scale)
```

Gathers single-precision (32-bit) floating-point elements from memory using 32-bit indices. 32-bit elements are loaded from addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*). Gathered elements are merged with *src* using mask *k*. When the corresponding mask bit is not set, elements are copied from *src*.

_mm512_i32extgather_ps

```
__m512 _mm512_i32extgather_ps (__m512i index, void const * mv, _MM_UPCONV_PS_ENUM upconv, int
scale, int hint)
```

Up-converts 16 memory locations starting at location *mv* using packed 32-bit integer indices stored in *index* scaled by *scale* using *upconv* to single-precision (32-bit) floating-point elements and stores them in dst.

_mm512_mask_i32extgather_ps

```
__m512 _mm512_mask_i32extgather_ps (__m512 src, __mmask16 k, __m512i index, void const * mv,
_MM_UPCONV_PS_ENUM upconv, int scale, int hint)
```

Up-converts 16 single-precision memory locations starting at location *mv* at packed 32-bit integer indices stored in *index* scaled by *scale* using *upconv* to single-precision (32-bit) floating-point elements and merges them with *src* using mask *k*. When the corresponding mask bit is not set, elements are copied from *src*.

_mm512_i64gather_pd

```
__m512d _mm512_i64gather_pd (__m512i vindex, void const* base_addr, int scale)
```

Gathers double-precision (64-bit) floating-point elements from memory using 64-bit indices. 64-bit elements are loaded from addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i64gather_pd

```
__m512d _mm512_mask_i64gather_pd (__m512d src, __mmask8 k, __m512i vindex, void const*
base_addr, int scale)
```

Gathers double-precision (64-bit) floating-point elements from memory using 64-bit indices. 64-bit elements are loaded from addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*). Gathered elements are merged with *src* using mask *k*. When the corresponding mask bit is not set, elements are copied from *src*.

_mm512_i64gather_ps

```
__m256 _mm512_i64gather_ps (__m512i vindex, void const* base_addr, int scale)
```

Gathers single-precision (32-bit) floating-point elements from memory using 64-bit indices. 32-bit elements are loaded from addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i64gather_ps

```
__m256 _mm512_mask_i64gather_ps (__m256 src, __mmask8 k, __m512i vindex, void const* base_addr,
int scale)
```

Gathers single-precision (32-bit) floating-point elements from memory using 64-bit indices. 32-bit elements are loaded from addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*). Gathered elements are merged with *src* using mask *k*. When the corresponding mask bit is not set, elements are copied from *src*.

_mm512_prefetch_i32gather_pd

```
void _mm512_prefetch_i32gather_pd (__m256i vindex, void const* base_addr, int scale, int hint)
```

Prefetches double-precision (64-bit) floating-point elements from memory using 32-bit indices. 64-bit elements are loaded from addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_prefetch_i32gather_pd

```
void _mm512_mask_prefetch_i32gather_pd (__m256i vindex, __mmask8 mask, void const* base_addr,
int scale, int hint)
```

Prefetches double-precision (64-bit) floating-point elements from memory using 32-bit indices. 64-bit elements are loaded from addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*). Gathered elements are merged with cache using mask *k*. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_prefetch_i32gather_ps

```
void _mm512_prefetch_i32gather_ps (__m512i index, void const* mv, int scale, int hint)
```

Prefetches 16 single-precision (32-bit) floating-point elements in memory starting at location *mv* at packed 32-bit integer indices stored in *index* (each index is scaled by the factor in *scale*).

_mm512_mask_prefetch_i32gather_ps

```
void _mm512_mask_prefetch_i32gather_ps (__m512i vindex, __mmask16 mask, void const* base_addr,
int scale, int hint)
```

Prefetches single-precision (32-bit) floating-point elements from memory using 32-bit indices. 32-bit elements are loaded from addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*). Gathered elements are merged with cache using mask *k*. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_prefetch_i64gather_pd

```
void _mm512_prefetch_i64gather_pd (__m512i vindex, void const* base_addr, int scale, int hint)
```

Prefetches double-precision (64-bit) floating-point elements from memory into cache level specified by *hint* using 64-bit indices. 64-bit elements are loaded from addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_prefetch_i64gather_pd

```
void _mm512_mask_prefetch_i64gather_pd (__m512i vindex, __mmask8 mask, void const* base_addr,
int scale, int hint)
```

Prefetches double-precision (64-bit) floating-point elements from memory into cache level specified by *hint* using 64-bit indices. 64-bit elements are loaded from addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*). Prefetched elements are merged with cache using mask *k*. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_prefetch_i64gather_ps

```
void _mm512_prefetch_i32gather_pd (__m256i vindex, void const* base_addr, int scale, int hint)
```

Prefetches single-precision (32-bit) floating-point elements from memory using 64-bit indices. 32-bit elements are loaded from addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_prefetch_i64gather_ps

```
void _mm512_mask_prefetch_i64gather_ps (__m512i vindex, __mmask8 mask, void const* base_addr,
int scale, int hint)
```

Prefetches single-precision (32-bit) floating-point elements from memory using 64-bit indices. 32-bit elements are loaded from addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*). Gathered elements are merged with cache using mask *k*. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_i32scatter_pd

```
void _mm512_i32scatter_pd (void* base_addr, __m256i vindex, __m512d a, int scale)
```

Scatters double-precision (64-bit) floating-point elements from *a* into memory using 32-bit indices. 64-bit elements are stored at addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i32scatter_pd

```
void _mm512_mask_i32scatter_pd (void* base_addr, __mmask8 k, __m256i vindex, __m512d a, int
scale)
```

Scatters double-precision (64-bit) floating-point elements from *a* into memory using 32-bit indices. 64-bit elements are stored at addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*) subject to mask *k*. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_i32scatter_ps

```
void _mm512_i32scatter_ps (void* base_addr, __m512i vindex, __m512 a, int scale)
```

Scatters single-precision (32-bit) floating-point elements from *a* into memory using 32-bit indices. 32-bit elements are stored at addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i32scatter_ps

```
void _mm512_mask_i32scatter_ps (void* base_addr, __mmask16 k, __m512i vindex, __m512 a, int
scale)
```

Scatters single-precision (32-bit) floating-point elements from *a* into memory using 32-bit indices. 32-bit elements are stored at addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*) subject to mask *k*. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_i32extscatter_ps

```
void _mm512_i32extscatter_ps (void * mv, __m512i index, __m512 v1, _MM_DOWNCONV_PS_ENUM
downconv, int scale, int hint)
```

Down-converts 16 packed single-precision (32-bit) floating-point elements in *v1* and stores them in memory locations starting at location *mv* at packed 32-bit integer indices stored in *index* scaled by *scale* using *downconv*.

_mm512_mask_i32extscatter_ps

```
void _mm512_mask_i32extscatter_ps (void * mv, __mmask16 k, __m512i index, __m512 v1,
_MM_DOWNCONV_PS_ENUM downconv, int scale, int hint)
```

Down-converts 16 packed single-precision (32-bit) floating-point elements in *v1* according to *downconv* and stores them in memory locations starting at location *mv* at packed 32-bit integer indices stored in *index* scaled by *scale* using mask *k*. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_i64scatter_pd

```
void _mm512_i64scatter_pd (void* base_addr, __m512i vindex, __m512d a, int scale)
```

Scatters double-precision (64-bit) floating-point elements from *a* into memory using 64-bit indices. 64-bit elements are stored at addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i64scatter_pd

```
void _mm512_mask_i64scatter_pd (void* base_addr, __mmask8 k, __m512i vindex, __m512d a, int
scale)
```

Scatters double-precision (64-bit) floating-point elements from *a* into memory using 64-bit indices. 64-bit elements are stored at addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*) subject to mask *k*. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_i64scatter_ps

```
void _mm512_i64scatter_ps (void* base_addr, __m512i vindex, __m256 a, int scale)
```

Scatters single-precision (32-bit) floating-point elements from *a* into memory using 64-bit indices. 32-bit elements are stored at addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i64scatter_ps

```
void _mm512_mask_i64scatter_ps (void* base_addr, __mmask8 k, __m512i vindex, __m256 a, int scale)
```

Scatters single-precision (32-bit) floating-point elements from *a* into memory using 64-bit indices. 32-bit elements are stored at addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*) subject to mask *k*. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_prefetch_i32scatter_pd

```
void _mm512_prefetch_i32scatter_pd (void* base_addr, __m256i vindex, int scale, int hint)
```

Prefetches double-precision (64-bit) floating-point elements with intent to write using 32-bit indices. 64-bit elements are brought into cache from addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_prefetch_i32scatter_pd

```
extern void __cdecl _mm512_mask_prefetch_i32gather_pd(__m256i vindex, __mmask8 k, void const*
base_addr, int scale, int hint);
```

Prefetches double-precision (64-bit) floating-point elements with intent to write using 32-bit indices. 64-bit elements are brought into cache from addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*) subject to mask *k*. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_prefetch_i32scatter_ps

```
void _mm512_prefetch_i32scatter_ps (void* mv, __m512i index, int scale, int hint)
```

Prefetches 16 single-precision (32-bit) floating-point elements in memory starting at location *mv* at packed 32-bit integer indices stored in *index* scaled by *scale*.

_mm512_mask_prefetch_i32scatter_ps

```
void _mm512_mask_prefetch_i32scatter_ps (void* mv, __mmask16 k, __m512i index, int scale, int
hint)
```

Prefetches 16 single-precision (32-bit) floating-point elements in memory starting at location *mv* at packed 32-bit integer indices stored in *index* scaled by *scale*. Elements are brought into cache only when their corresponding mask bits in mask *k* are set.

_mm512_prefetch_i64scatter_pd

```
void _mm512_prefetch_i64scatter_pd (void* base_addr, __m512i vindex, int scale, int hint)
```

Prefetches double-precision (64-bit) floating-point elements with intent to write into memory using 64-bit indices. 64-bit elements are brought into cache from addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_prefetch_i64scatter_pd

```
void _mm512_mask_prefetch_i64scatter_pd (void* base_addr, __mmask8 mask, __m512i vindex, int
scale, int hint)
```

Prefetches double-precision (64-bit) floating-point elements with intent to write into memory using 64-bit indices. 64-bit elements are brought into cache from addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*) subject to mask *k*. Elements are brought into cache only when their corresponding mask bits are set.

_mm512_prefetch_i64scatter_ps

```
void _mm512_prefetch_i64scatter_ps (void* base_addr, __m512i vindex, int scale, int hint)
```

Prefetches single-precision (32-bit) floating-point elements with intent to write into memory using 64-bit indices. 32-bit elements are stored at addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_prefetch_i64scatter_ps

```
void _mm512_mask_prefetch_i64scatter_ps (void* base_addr, __mmask8 mask, __m512i vindex, int
scale, int hint)
```

Prefetches single-precision (32-bit) floating-point elements with intent to write into memory using 64-bit indices. 32-bit elements are stored at addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*) subject to mask *k*. Elements are brought into cache only when their corresponding mask bits are set.

Intrinsics for Integer Gather and Scatter Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_i32gather_epi32`, `_mm512_mask_i32gather_epi32`	Gathers 32-bit integers from memory using 32-bit indices.	`VPGATHERDD`
`_mm512_i32gather_epi64`, `_mm512_mask_i32gather_epi64`	Gathers 64-bit integers from memory using 32-bit indices.	`VPGATHERDQ`
`_mm512_i64gather_epi32`, `_mm512_mask_i64gather_epi32`	Gathers 32-bit integers from memory using 64-bit indices.	`VPGATHERQD`
`_mm512_i64gather_epi64`, `_mm512_mask_i64gather_epi64`	Gathers 64-bit integers from memory using 64-bit indices.	`VPGATHERQQ`
`_mm512_i32scatter_epi32`, `_mm512_mask_i32scatter_epi32`	Scatters 32-bit integers into memory using 32-bit indices.	`VPSCATTERDD`

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_i32scatter_epi64`, `_mm512_mask_i32scatter_epi64`	Scatters 64-bit integers into memory using 32-bit indices.	`VPSCATTERDQ`
`_mm512_i64scatter_epi32`, `_mm512_mask_i64scatter_epi32`	Scatters 32-bit integers into memory using 64-bit indices.	`VPSCATTERQD`
`_mm512_i64scatter_epi64`, `_mm512_mask_i64scatter_epi64`	Scatters 64-bit integers into memory using 64-bit indices.	`VPSCATTERQQ`

variable	definition
vindex	a vector of indices
base_addr	a pointer to the base address in memory
scale	a compilation-time literal constant that is used as the vector indices scale. Possible values are 1, 2, 4, or 8.
k	mask used as a selector
a	first source vector element
src	source element to use based on the mask result

_mm512_i32gather_epi32

```
__m512i _mm512_i32gather_epi32(__m512i vindex, void const* base_addr, int scale)
```

Gathers 32-bit integers from memory using 32-bit indices. 32-bit elements are loaded from addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i32gather_epi32

```
__m512i _mm512_mask_i32gather_epi32(__m512i src, __mmask16 k, __m512i vindex, void const*
base_addr, int scale)
```

Gathers 32-bit integers from memory using 32-bit indices. 32-bit elements are loaded from addresses starting at `base_addr` and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*). Gathered elements are merged with *src* using mask *k*. When the corresponding mask bit is not set, elements are copied from *src*.

_mm512_i32gather_epi64

```
__m512i _mm512_mask_i32gather_epi64 (__m512i src, __mmask8 k, __m256i vindex, void const*
base_addr, int scale)
```

Gathers 64-bit integers from memory using 32-bit indices. 64-bit elements are loaded from addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i32gather_epi64

```
__m512i _mm512_mask_i32gather_epi64 (__m512i src, __mmask8 k, __m256i vindex, void const*
base_addr, int scale)
```

Gathers 64-bit integers from memory using 32-bit indices. 64-bit elements are loaded from addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*). Gathered elements are merged with *src* using mask *k*. When the corresponding mask bit is not set, elements are copied from *src*.

_mm512_i64gather_epi32

```
__m256i _mm512_i64gather_epi32 (__m512i vindex, void const* base_addr, int scale)
```

Gathers 32-bit integers from memory using 64-bit indices. 32-bit elements are loaded from addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i64gather_epi32

```
__m256i _mm512_mask_i64gather_epi32 (__m256i src, __mmask8 k, __m512i vindex, void const*
base_addr, int scale)
```

Gathers 32-bit integers from memory using 64-bit indices. 32-bit elements are loaded from addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*). Gathered elements are merged with *src* using mask *k*. When the corresponding mask bit is not set, elements are copied from *src*.

_mm512_i64gather_epi64

```
__m512i _mm512_i64gather_epi64 (__m512i vindex, void const* base_addr, int scale)
```

Gathers 64-bit integers from memory using 64-bit indices. 64-bit elements are loaded from addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i64gather_epi64

```
__m512i _mm512_mask_i64gather_epi64 (__m512i src, __mmask8 k, __m512i vindex, void const*
base_addr, int scale)
```

Gathers 64-bit integers from memory using 64-bit indices. 64-bit elements are loaded from addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*). Gathered elements are merged with *src* using mask *k*. When the corresponding mask bit is not set, elements are copied from *src*.

_mm512_i32scatter_epi32

```
void mm512_i32scatter_epi32(void* base_addr, __m512i vindex, __m512i a, int scale)
```

Scatters 32-bit integers from *a* into memory using 32-bit indices. 32-bit elements are stored at addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i32scatter_epi32

```
void _mm512_mask_i32scatter_epi32(void* base_addr, __mmask16 k, __m512i vindex, __m512i a, int
scale
```

Scatters 32-bit integers from *a* into memory using 32-bit indices. 32-bit elements are stored at addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*) subject to mask *k*. When the corresponding mask bit is not set, elements are not stored.

_mm512_i32scatter_epi64

```
void _mm512_i32scatter_epi64 (void* base_addr, __m256i vindex, __m512i a, int scale)
```

Scatters 64-bit integers from *a* into memory using 32-bit indices. 64-bit elements are stored at addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i32scatter_epi64

```
void _mm512_mask_i32scatter_epi64 (void* base_addr, __mmask8 k, __m256i vindex, __m512i a, int
scale)
```

Scatters 64-bit integers from *a* into memory using 32-bit indices. 64-bit elements are stored at addresses starting at *base_addr* and offset by each 32-bit element in *vindex* (each index is scaled by the factor in *scale*) subject to mask *k*. When the corresponding mask bit is not set, elements are not stored.

_mm512_i64scatter_epi32

```
void _mm512_i64scatter_epi32 (void* base_addr, __m512i vindex, __m256i a, int scale)
```

Scatters 32-bit integers from *a* into memory using 64-bit indices. 32-bit elements are stored at addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i64scatter_epi32

```
void _mm512_mask_i64scatter_epi32 (void* base_addr, __mmask8 k, __m512i vindex, __m256i a, int
scale)
```

Scatters 32-bit integers from *a* into memory using 64-bit indices. 32-bit elements are stored at addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*) subject to mask *k*. When the corresponding mask bit is not set, elements are not stored.

_mm512_i64scatter_epi64

```
void _mm512_i64scatter_epi64 (void* base_addr, __m512i vindex, __m512i a, int scale)
```

Scatters 64-bit integers from *a* into memory using 64-bit indices. 64-bit elements are stored at addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*).

_mm512_mask_i64scatter_epi64

```
void _mm512_mask_i64scatter_epi64 (void* base_addr, __mmask8 k, __m512i vindex, __m512i a, int
scale)
```

Scatters 64-bit integers from *a* into memory using 64-bit indices. 64-bit elements are stored at addresses starting at *base_addr* and offset by each 64-bit element in *vindex* (each index is scaled by the factor in *scale*) subject to mask *k*. When the corresponding mask bit is not set, elements are not stored.

Intrinsics for Insert and Extract Operations

Intrinsics for FP Insert and Extract Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_extractf32x4_ps, _mm512_mask_extractf32x4_ps, _mm512_maskz_extractf32x4_ps	Extract float32 values.	VEXTRACTF32X4
_mm512_extractf64x4_pd_mm512_mask_extractf64x4_pd, _mm512_maskz_extractf64x4_pd	Extract float64 values.	VEXTRACTF64X4
_mm_extract_ps	Extract packed float32 values.	EXTRACTPS
_mm512_getmant_pd, _mm512_mask_getmant_pd, _mm512_maskz_getmant_pd _mm512_getmant_round_pd, _mm512_mask_getmant_round_pd, _mm512_maskz_getmant_round_pd	Extract float64 vector of normalized mantissas from float64 vector.	VGETMANTPD

_mm512_insertf64x4, _mm512_mask_insertf64x4, _mm512_mask_insertf64x4	Insert float64 values.	VINSERTF64X4
_mm_insert_ps	Insert scalar float32 values.	VINSERTPS/INSERTPS

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result
imm	8-bit immediate integer specifies offset for destination
tmp	temporary storage location used during operation
interval	Where `_MM_MANTISSA_NORM_ENUM` can be one of the following: • `_MM_MANT_NORM_1_2` - interval [1, 2) • `_MM_MANT_NORM_p5_2` - interval [1.5, 2) • `_MM_MANT_NORM_p5_1` - interval [1.5, 1) • `_MM_MANT_NORM_p75_1p5` - interval [0.75, 1.5)
sign	Where `_MM_MANTISSA_SIGN_ENUM` can be one of the following: • `_MM_MANT_SIGN_src` - sign = sign(SRC) • `_MM_MANT_SIGN_zero` - sign = 0 • `_MM_MANT_SIGN_nan` - DEST = NaN if sign(SRC) = 1
round	Rounding control values; these can be one of the following (along with the `sae` suppress all exceptions flag): • `_MM_FROUND_TO_NEAREST_INT` - rounds to nearest even • `_MM_FROUND_TO_NEG_INF` - rounds to negative infinity • `_MM_FROUND_TO_POS_INF` - rounds to positive infinity • `_MM_FROUND_TO_ZERO` - rounds to zero • `_MM_FROUND_CUR_DIRECTION` - rounds using default from MXCSR register

_mm512_extractf32x4_ps

```
extern __m128 __cdecl _mm512_extractf32x4_ps(__m512 a, int imm);
```

Extracts 128 bits (composed of four packed float32 elements) from *a*, selected with *imm*, and stores the result.

_mm512_mask_extractf32x4_ps

```
extern __m128 __cdecl _mm512_mask_extractf32x4_ps(__m128 src, __mmask8 k, __m512 a, int imm);
```

Extracts 128 bits (composed of four packed float32 elements) from *a*, selected with *imm*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_extractf32x4_ps

```
extern __m128 __cdecl _mm512_maskz_extractf32x4_ps(__mmask8 k, __m512, int imm);
```

Extracts 128 bits (composed of four packed float32 elements) from *a*, selected with *imm*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_extractf64x4_pd

```
extern __m256d __cdecl _mm512_extractf64x4_pd(__m512d a, int imm);
```

Extracts 256 bits (composed of four packed float64 elements) from *a*, selected with *imm*, and stores the result.

_mm512_mask_extractf64x4_pd

```
extern __m256d __cdecl _mm512_mask_extractf64x4_pd(__m256d src, __mmask8 k, __m512d a, int imm);
```

Extracts 256 bits (composed of four packed float64 elements) from *a*, selected with *imm*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_extractf64x4_pd

```
extern __m256d __cdecl _mm512_maskz_extractf64x4_pd(__mmask8 k, __m512d a, int imm);
```

Extracts 256 bits (composed of four packed float64 elements) from *a*, selected with *imm*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_insertf32x4

```
extern __m512 __cdecl _mm512_insertf32x4(__m512 a, __m128 b, int imm);
```

Copies *a* to destination, then inserts 128 bits (composed of four packed float32 elements) from *b* into destination at the location specified by *imm*.

_mm512_mask_insertf32x4

```
extern __m512 __cdecl _mm512_mask_insertf32x4(__m512 src, __mmask16 k, __m512 a, __m128 b, int
imm);
```

Copies *a* to destination, then inserts 128 bits (composed of four packed float32 elements) from *b* into destination at the location specified by *imm*.

_mm512_maskz_insertf32x4

```
extern __m512 __cdecl _mm512_maskz_insertf32x4(__mmask16 k, __m512 a, __m128 b, int imm);
```

Copies *a* to *tmp*, then inserts 128 bits (composed of four packed float32 elements) from *b* into *tmp* at the location specified by *imm*. Stores *tmp* to destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_insertf64x4

```
extern __m512d __cdecl _mm512_insertf64x4(__m512d a, __m256d b, int imm);
```

Copies *a* to *tmp*, then inserts 128 bits (composed of four packed float32 elements) from *b* into *tmp* at the location specified by *imm*. Stores *tmp* to destination using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mask_insertf64x4

```
extern __m512d __cdecl _mm512_mask_insertf64x4(__m512d src, __mmask8 k, __m512d a, __m256d b,
int imm);
```

Copies *a* to destination, then inserts 256 bits (composed of four packed float64 elements) from *b* into destination at the location specified by *imm*.

_mm512_maskz_insertf64x4

```
extern __m512d __cdecl _mm512_maskz_insertf64x4(__mmask8 k, __m512d a, __m256d b, int imm);
```

Copies *a* to *tmp*, then inserts 256 bits (composed of four packed float64 elements) from *b* into *tmp* at the location specified by *imm*. Store *tmp* to destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_getmant_pd

```
extern __m512d __cdecl _mm512_getmant_pd(__m512d a, _MM_MANTISSA_NORM_ENUM interval,
_MM_MANTISSA_SIGN_ENUM sign);
```

Normalizes the mantissas of packed float64 elements in *a*, and stores the result. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm512_mask_getmant_pd

```
extern __m512d __cdecl _mm512_mask_getmant_pd(__m512d src, __mmask8 k, __m512d a,
_MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign);
```

Normalizes the mantissas of packed float64 elements in *a*, and stores the result. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm512_maskz_getmant_pd

```
extern __m512d __cdecl _mm512_maskz_getmant_pd(__mmask8 k, __m512d a, _MM_MANTISSA_NORM_ENUM
interval, _MM_MANTISSA_SIGN_ENUM sign);
```

Normalizes the mantissas of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set). This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm512_getmant_round_pd

```
extern __m512d __cdecl _mm512_getmant_round_pd(__m512d a, _MM_MANTISSA_NORM_ENUM interval,
_MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of packed float64 elements in *a*, and stores the result. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm512_mask_getmant_round_pd

```
extern __m512d __cdecl _mm512_mask_getmant_round_pd(__m512d src, __mmask8 k, __m512d a,
_MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set). This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm512_maskz_getmant_round_pd

```
extern __m512d __cdecl _mm512_maskz_getmant_round_pd(__mmask8 k, __m512d a,
_MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of packed float64 elements in *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set). This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm512_getmant_ps

```
extern __m512 __cdecl _mm512_getmant_ps(__m512 a, _MM_MANTISSA_NORM_ENUM interval,
_MM_MANTISSA_SIGN_ENUM sign);
```

Normalizes the mantissas of packed float32 elements in *a*, and stores the result. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm512_mask_getmant_ps

```
extern __m512 __cdecl _mm512_mask_getmant_ps(__m512 src, __mmask16 k, __m512 a,
_MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign);
```

Normalizes the mantissas of packed float32 elements in *a*, and stores the result. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm512_maskz_getmant_ps

```
extern __m512 __cdecl _mm512_maskz_getmant_ps(__mmask16 k, __m512 a, _MM_MANTISSA_NORM_ENUM
interval, _MM_MANTISSA_SIGN_ENUM sign);
```

Normalizes the mantissas of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set). This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm512_getmant_round_ps

```
extern __m512 __cdecl _mm512_getmant_round_ps(__m512 a, _MM_MANTISSA_NORM_ENUM interval,
_MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of packed float32 elements in *a*, and stores the result. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm512_mask_getmant_round_ps

```
extern __m512 __cdecl _mm512_mask_getmant_round_ps(__m512 src, __mmask16 k, __m512 a,
_MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set). This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm512_maskz_getmant_round_ps

```
extern __m512 __cdecl _mm512_maskz_getmant_round_ps(__mmask16 k, __m512 a,
_MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of packed float32 elements in *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set). This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm_getmant_round_sd

```
extern __m128d __cdecl _mm_getmant_round_sd(__m128d a, __m128d b, _MM_MANTISSA_NORM_ENUM
interval, _MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of the lower float64 element in *a*, stores the result in the lower destination element, and copies the upper element from *b* to the upper destination element. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm_mask_getmant_round_sd

```
extern __m128d __cdecl _mm_mask_getmant_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b,
_MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of the lower float64 element in *a*, store the result in the lower destination element, and copies the upper element from *b* to the upper destination element. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm_maskz_getmant_round_sd

```
extern __m128d __cdecl _mm_maskz_getmant_round_sd(__mmask8 k, __m128d a, __m128d b,
_MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of the lower float64 element in *a*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper element from *b* to the upper destination element. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm_getmant_sd

```
extern __m128d __cdecl _mm_getmant_sd(__m128d a, __m128d b, _MM_MANTISSA_NORM_ENUM interval,
_MM_MANTISSA_SIGN_ENUM sign);
```

Normalizes the mantissas of the lower float64 element in *a*, store the result in the lower destination element, and copies the upper element from *b* to the upper destination element. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm_mask_getmant_sd

```
extern __m128d __cdecl _mm_mask_getmant_sd(__m128d a, __mmask8 k, __m128d b, __m128d c,
_MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign);
```

Normalize the mantissas of the lower float64 element in *a*, store the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copy the upper element from *b* to the upper destination element. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm_maskz_getmant_sd

```
extern __m128d __cdecl _mm_maskz_getmant_sd(__mmask8 k, __m128d a, __m128d b,
_MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign);
```

Normalizes the mantissas of the lower float64 element in *a*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper element from *b* to the upper destination element. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm_getmant_round_ss

```
extern __m128 __cdecl _mm_getmant_round_ss(__m128 a, __m128 b, _MM_MANTISSA_NORM_ENUM interval,
_MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of the lower float32 element in *a*, stores the result in the lower destination element, and copies the upper three packed elements from *b* to the upper destination elements. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm_mask_getmant_round_ss

```
extern __m128 __cdecl _mm_mask_getmant_round_ss(__m128 a, __mmask8 k, __m128 b, __m128 c,
_MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of the lower float32 element in *a*, stores the result in the lower destination element, and copies the upper three packed elements from *b* to the upper destination elements. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm_maskz_getmant_round_ss

```
extern __m128 __cdecl _mm_maskz_getmant_round_ss(__mmask8 k, __m128 a, __m128 b,
_MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign, int round);
```

Normalizes the mantissas of the lower float32 element in *a*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper three packed elements from *b* to the upper destination elements. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm_getmant_ss

```
extern __m128 __cdecl _mm_getmant_ss(__m128 a, __m128 b, _MM_MANTISSA_NORM_ENUM interval,
_MM_MANTISSA_SIGN_ENUM sign);
```

Normalizes the mantissas of the lower float32 element in *a*, stores the result in the lower destination element, and copies the upper three packed elements from *b* to the upper destination elements. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm_mask_getmant_ss

```
extern __m128 __cdecl _mm_mask_getmant_ss(__m128 a, __mmask8 k, __m128 b, __m128 c,
_MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign);
```

Normalizes the mantissas of the lower float32 element in *a*, stores the result in the lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies the upper three packed elements from *b* to the upper destination elements. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

_mm_maskz_getmant_ss

```
extern __m128 __cdecl _mm_maskz_getmant_ss(__mmask8 k, __m128 a, __m128 b,
_MM_MANTISSA_NORM_ENUM interval, _MM_MANTISSA_SIGN_ENUM sign);
```

Normalizes the mantissas of the lower float32 element in *a*, stores the result in the lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies the upper three packed elements from *b* to the upper destination elements. This intrinsic essentially calculates `±(2^k)*|x.significand|`, where *k* depends on the interval range defined by *interval* and the sign depends on *sign* and the source sign.

Intrinsics for Integer Insert and Extract Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_extracti32x4_epi32`, `_mm512_mask_extracti32x4_epi32`, `_mm512_maskz_extracti32x4_epi32`	Extracts int32 values.	`VEXTRACTI32X4`
`_mm512_extracti64x4_epi64`, `_mm512_mask_extracti64x4_epi64`, `_mm512_maskz_extracti64x4_epi64`	Extracts int64 values.	`VEXTRACTI64X4`
`_mm512_inserti32x4_epi32`, `_mm512_mask_inserti32x4_epi32`, `_mm512_maskz_inserti32x4_epi32`	Inserts int32 values.	`VINSERTI32X4`
`_mm512_inserti64x4_epi64`, `_mm512_mask_inserti64x4_epi64`, `_mm512_maskz_inserti64x4_epi64`	Inserts int64 values.	`VINSERTI64X4`

variable	definition
k	writemask used as a selector
a	first source vector element
mem_addr	pointer to base address in memory
src	source element to use based on writemask result

variable	definition
tmp	temporary location specified by imm
imm	specifies temporary location *tmp*

_mm512_extracti32x4_epi32

```
extern __m128i __cdecl _mm512_extracti32x4_epi32(__m512i a, int imm);
```

Extracts 128 bits (composed of four packed 32-bit integers) from *a*, selected with *imm*, and stores the result.

_mm512_mask_extracti32x4_epi32

```
extern __m128i __cdecl _mm512_mask_extracti32x4_epi32(__m128i src, __mmask8 k, __m512i a, int
imm);
```

Extracts 128 bits (composed of four packed 32-bit integers) from *a*, selected with *imm*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_extracti32x4_epi32

```
extern __m128i __cdecl _mm512_maskz_extracti32x4_epi32(__mmask8 k, __m512i a, int imm);
```

Extracts 128 bits (composed of four packed 32-bit integers) from *a*, selected with *imm*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_extracti64x4_epi64

```
extern __m256i __cdecl _mm512_extracti64x4_epi64(__m512i a, int imm);
```

Extracts 256 bits (composed of four packed int64 elements) from *a*, selected with *imm*, and stores the result.

_mm512_mask_extracti64x4_epi64

```
extern __m256i __cdecl _mm512_mask_extracti64x4_epi64(__m256i src, __mmask8 k, __m512i a, int
imm);
```

Extracts 256 bits (composed of four packed int64 elements) from *a*, selected with *imm*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_extracti64x4_epi64

```
extern __m256i __cdecl _mm512_maskz_extracti64x4_epi64(__mmask8 k, __m512i a, int imm);
```

Extracts 256 bits (composed of four packed int64 elements) from *a*, selected with *imm*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_inserti32x4

```
extern __m512i __cdecl _mm512_inserti32x4(__m512i a, __m128i b, int imm);
```

Copies *a* to destination, then inserts 128 bits (composed of four packed 32-bit integers) from *b* into destination at the location specified by *imm*.

_mm512_mask_inserti32x4

```
extern __m512i __cdecl _mm512_mask_inserti32x4(__m512i src, __mmask16 k, __m512i a, __m128i b,
int imm);
```

Copies *a* to *tmp*, then inserts 128 bits (composed of four packed 32-bit integers) from *b* into *tmp* at the location specified by *imm*. Store *tmp* to using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_inserti32x4

```
extern __m512i __cdecl _mm512_maskz_inserti32x4(__mmask16 k, __m512i a, __m128i b, int imm);
```

Copies *a* to *tmp*, then inserts 256 bits (composed of four packed double-precision (64-bit) floating-point elements) from *b* into *tmp* at the location specified by *imm*.

Store *tmp* to destination using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_inserti64x4

```
extern __m512i __cdecl _mm512_inserti64x4(__m512i a, __m256i b, int imm);
```

Copies *a* to *tmp*, then inserts 256 bits (composed of four packed int64 elements) from *b* into *tmp* at the location specified by *imm*.

_mm512_mask_inserti64x4

```
extern __m512i __cdecl _mm512_mask_inserti64x4(__m512i src, __mmask8 k, __m512i a, __m256i b,
int imm);
```

Copies *a* to *tmp*, then inserts 256 bits (composed of four packed int64 elements) from *b* into *tmp* at the location specified by *imm*. Store *tmp* to using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_inserti64x4

```
extern __m512i __cdecl _mm512_maskz_inserti64x4(__mmask8 k, __m512i a, __m256i b, int imm);
```

Copies *a* to *tmp*, then inserts 128 bits (composed of four packed 32-bit integers) from *b* into *tmp* at the location specified by *imm*. Store *tmp* to using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

variable	definition
k	writemask used as a selector
a	first source vector element
src	source element to use based on writemask result
mem_addr	pointer to base address in memory

_mm512_load_pd

```
extern __m512d __cdecl _mm512_load_pd(void const* mem_addr);
```

Loads 512-bits (composed of eight packed float64 elements) from *mem_addr* into destination.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_load_pd

```
extern __m512d __cdecl _mm512_mask_load_pd(__m512d src, __mmask8 k, void const* mem_addr);
```

Loads packed float64 elements from *mem_addr* into destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_maskz_load_pd

```
extern __m512d __cdecl _mm512_maskz_load_pd(__mmask8 k, void const* mem_addr);
```

Loads packed float64 elements from *mem_addr* into destination using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_load_ps

```
extern __m512 __cdecl _mm512_load_ps(void const* mem_addr);
```

Loads 512-bits (composed of sixteen packed float32 elements) from *mem_addr* into destination.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_load_ps

```
extern __m512 __cdecl _mm512_mask_load_ps(__m512 src, __mmask16 k, void const* mem_addr);
```

Loads packed float32 elements from *mem_addr* into destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_maskz_load_ps

```
extern __m512 __cdecl _mm512_maskz_load_ps(__mmask16 k, void const*  mem_addr);
```

Loads packed float32 elements from *mem_addr* into destination using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm_mask_load_sd

```
extern __m128d __cdecl _mm_mask_load_sd(__m128d src, __mmask8 k, const double* mem_addr);
```

Loads float64 element from *mem_addr* into lower element of destination using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and sets upper destination element to zero.

mem_addr must be aligned on a 16-byte boundary or a general-protection exception will be generated.

_mm_maskz_load_sd

```
extern __m128d __cdecl _mm_maskz_load_sd(__mmask8 k, const double* mem_addr);
```

Loads a float64 element from *mem_addr* into lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and sets upper destination elements to zero.

mem_addr must be aligned on a 16-byte boundary or a general-protection exception will be generated.

_mm_mask_load_ss

```
extern __m128 __cdecl _mm_mask_load_ss(__m128 src, __mmask8 k, const float* mem_addr);
```

Loads float32 element from *mem_addr* into lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and sets upper destination elements to zero.

mem_addr must be aligned on a 16-byte boundary or a general-protection exception will be generated.

_mm_maskz_load_ss

```
extern __m128 __cdecl _mm_maskz_load_ss(__mmask8 k, const float* mem_addr);
```

Loads float32 element from *mem_addr* into lower element of destination using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and sets upper destination elements to zero.

mem_addr must be aligned on a 16-byte boundary or a general-protection exception will be generated.

_mm512_loadu_pd

```
extern __m512d __cdecl _mm512_loadu_pd(void const* mem_addr);
```

Loads 512-bits (composed of eight packed float64 elements) from *mem_addr* into destination.

mem_addr does not need to be aligned on any particular boundary.

_mm512_mask_loadu_pd

```
extern __m512d __cdecl _mm512_mask_loadu_pd(__m512d src, __mmask8 k, void const* mem_addr);
```

Loads packed float64 elements from *mem_addr* into destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

mem_addr does not need to be aligned on any particular boundary.

_mm512_maskz_loadu_pd

```
extern __m512d __cdecl _mm512_maskz_loadu_pd(__mmask8 k, void const* mem_addr);
```

Loads packed float64 elements from *mem_addr* into destination using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

mem_addr does not need to be aligned on any particular boundary.

_mm512_loadu_ps

```
extern __m512 __cdecl _mm512_loadu_ps(void const* mem_addr);
```

Loads 512-bits (composed of sixteen packed float32 elements) from *mem_addr* into destination.

_mm512_mask_loadu_ps

```
extern __m512 __cdecl _mm512_mask_loadu_ps(__m512 src, __mmask16 k, void const* mem_addr);
```

Loads packed float32 elements from *mem_addr* into destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_loadu_ps

```
extern __m512 __cdecl _mm512_maskz_loadu_ps(__mmask16 k, void const* mem_addr);
```

Loads packed float32 elements from *mem_addr* into destination using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

mem_addr does not need to be aligned on any particular boundary.

_mm512_store_pd

```
extern void __cdecl _mm512_store_pd(void* mem_addr, __m512d a);
```

Stores 512-bits (composed of eight packed float64 elements) from *a* into *mem_addr*.

_mm512_mask_store_pd

```
extern void __cdecl _mm512_mask_store_pd(void* mem_addr, __mmask8 k, __m512d a);
```

Stores packed float64 elements from *a* into *mem_addr* using writemask *k*.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_store_ps

```
extern void __cdecl _mm512_store_ps(void* mem_addr, __m512 a);
```

Store 512-bits (composed of sixteen packed float32 elements) from *a* into *mem_addr*.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_store_ps

```
extern void __cdecl _mm512_mask_store_ps(void* mem_addr, __mmask16 k, __m512 a);
```

Store packed float32 elements from *a* into *mem_addr* using writemask *k*.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_stream_pd

```
extern void __cdecl _mm512_stream_pd(void* mem_addr, __m512d a);
```

Stores 512-bits (composed of eight packed float64 elements) from *a* into *mem_addr* using a non-temporal memory hint.

_mm512_stream_ps

```
extern void __cdecl _mm512_stream_ps(void* mem_addr, __m512 a);
```

Stores 512-bits (composed of sixteen packed float32 elements) from *a* into *mem_addr* using a non-temporal memory hint.

_mm_mask_store_sd

```
extern void __cdecl _mm_mask_store_sd(double* mem_addr, __mmask8 k, __m128d a);
```

Stores lower float64 element from *a* into *mem_addr* using writemask *k*.

mem_addr must be aligned on a 16-byte boundary or a general-protection exception will be generated.

_mm_mask_store_ss

```
extern void __cdecl _mm_mask_store_ss(float* mem_addr, __mmask8 k, __m128 a);
```

Stores lower float32 element from *a* into *mem_addr* using writemask *k*.

mem_addr must be aligned on a 16-byte boundary or a general-protection exception will be generated.

_mm512_storeu_pd

```
extern void __cdecl _mm512_storeu_pd(void* mem_addr, __m512d a);
```

Stores 512-bits (composed of eight packed float64 elements) from *a* into *mem_addr*.

mem_addr does not need to be aligned on any particular boundary.

_mm512_mask_storeu_pd

```
extern void __cdecl _mm512_mask_storeu_pd(void* mem_addr, __mmask8 k, __m512d a);
```

Stores packed float64 elements from *a* into *mem_addr* using writemask *k*.

mem_addr does not need to be aligned on any particular boundary.

_mm512_storeu_ps

```
extern void __cdecl _mm512_storeu_ps(void* mem_addr, __m512 a);
```

Stores 512-bits (composed of sixteen packed float32 elements) from *a* into *mem_addr*.

mem_addr does not need to be aligned on any particular boundary.

_mm512_mask_storeu_ps

```
extern void __cdecl _mm512_mask_storeu_ps(void* mem_addr, __mmask16 k, __m512 a);
```

Stores packed float32 elements from *a* into *mem_addr* using writemask *k*.

Intrinsics for Integer Load and Store Operations

The prototypes for Intel© Advanced Vector Extensions 512 (Intel© AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_load_epi32`, `_mm512_mask_load_epi32`, `_mm512_maskz_load_epi32`	Load packed int32 elements from memory	`VMOVDQA32`
`_mm512_load_epi64`, `_mm512_mask_load_epi64`, `_mm512_maskz_load_epi64`	Load packed int64 elements from memory	`VMOVDQA64`
`_mm512_loadu_si512`	Unaligned load of 512-bit scalar integer	`VMOVDQU32`
`_mm512_mask_loadu_epi32`, `_mm512_maskz_loadu_epi32`	Unaligned load of packed int32 elements	`VMOVDQU32`
`_mm512_mask_loadu_epi64`, `_mm512_maskz_loadu_epi64`	Unaligned load of packed int64 elements	`VMOVDQU64`

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_stream_load_si512`	Load double quadword using non-temporal aligned hint.	`MOVNTDQA`
`_mm512_mask_storeu_epi64`	Store unaligned packed int64 elements	`VMOVDQU64`
`_mm512_stream_si512`	Store packed integer values using non-temporal hint.	`VMOVNTDQA`

variable	definition
k	writemask used as a selector
a	first source vector element
mem_addr	pointer to base address in memory
src	source element to use based on writemask result

_mm512_load_si512

```
extern __m512i __cdecl _mm512_load_si512(void const* mem_addr);
```

Load 512-bits of integer data from memory into destination.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_loadu_si512

```
extern __m512i __cdecl _mm512_loadu_si512(void const* mem_addr);
```

Load 512-bits of integer data from memory into destination.

mem_addr does not need to be aligned on any particular boundary.

_mm512_load_epi32

```
extern __m512i __cdecl _mm512_load_epi32(void const* mem_addr);
```

Load 512-bits (composed of sixteen packed 32-bit integers) from memory into destination.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_load_epi32

```
extern __m512i __cdecl _mm512_mask_load_epi32(__m512i src, __mmask16 k, void const* mem_addr);
```

Load packed int32 elements from memory into destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_maskz_load_epi32

```
extern __m512i __cdecl _mm512_maskz_load_epi32(__mmask16 k, void const* mem_addr);
```

Load packed int32 elements from memory into destination using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_load_epi64

```
extern __m512i __cdecl _mm512_load_epi64(void const* mem_addr);
```

Load 512-bits (composed of eight packed int64 elements) from memory into destination.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_load_epi64

```
extern __m512i __cdecl _mm512_mask_load_epi64(__m512i src, __mmask8 k, void const* mem_addr);
```

Load packed int64 elements from memory into destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_maskz_load_epi64

```
extern __m512i __cdecl _mm512_maskz_load_epi64(__mmask8 k, void const* mem_addr);
```

Load packed int64 elements from memory into destination using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_loadu_epi32

```
extern __m512i __cdecl _mm512_mask_loadu_epi32(__m512i src, __mmask16 k, void const* mem_addr);
```

Load packed int32 elements from memory into destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

mem_addr does not need to be aligned on any particular boundary.

_mm512_maskz_loadu_epi32

```
extern __m512i __cdecl _mm512_maskz_loadu_epi32(__mmask16 k, void const* mem_addr);
```

Load packed int32 elements from memory into destination using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

mem_addr does not need to be aligned on any particular boundary.

_mm512_mask_loadu_epi64

```
extern __m512i __cdecl _mm512_mask_loadu_epi64(__m512i src, __mmask8 k, void const* mem_addr);
```

Load packed int64 elements from memory into destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

mem_addr does not need to be aligned on any particular boundary.

_mm512_stream_load_si512

```
extern __m512i __cdecl _mm512_stream_load_si512(void * mem_addr);
```

Load 512-bits of integer data from memory into destination using a non-temporal memory hint.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_store_epi32

```
extern void __cdecl _mm512_store_epi32(void* mem_addr, __m512i a);
```

Store 512-bits (composed of sixteen packed 32-bit integers) from *a* into memory.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_store_epi32

```
extern void __cdecl _mm512_mask_store_epi32(void* mem_addr, __mmask16 k, __m512i a);
```

Store packed int32 elements from *a* into memory using writemask *k*.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_store_si512

```
extern void __cdecl _mm512_store_si512(void* mem_addr, __m512i a);
```

Store 512-bits of integer data from *a* into memory.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_store_epi64

```
extern void __cdecl _mm512_store_epi64(void* mem_addr, __m512i a);
```

Store 512-bits (composed of eight packed int64 elements) from *a* into memory.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_store_epi64

```
extern void __cdecl _mm512_mask_store_epi64(void* mem_addr, __mmask8 k, __m512i a);
```

Store packed int64 elements from *a* into memory using writemask *k*.

mem_addr must be aligned on a 64-byte boundary or a general-protection exception will be generated.

_mm512_mask_storeu_epi32

```
extern void __cdecl _mm512_mask_storeu_epi32(void* mem_addr, __mmask16 k, __m512i a);
```

Store packed int32 elements from *a* into memory using writemask *k*.

mem_addr does not need to be aligned on any particular boundary.

_mm512_mask_storeu_epi64

```
extern void __cdecl _mm512_mask_storeu_epi64(void* mem_addr, __mmask8 k, __m512i a);
```

Store packed int64 elements from *a* into memory using writemask *k*.

mem_addr does not need to be aligned on any particular boundary.

_mm512_storeu_si512

```
extern void __cdecl _mm512_storeu_si512(void* mem_addr, __m512i a);
```

Store 512-bits of integer data from *a* into memory.

mem_addr does not need to be aligned on any particular boundary.

_mm512_stream_si512

```
extern void __cdecl _mm512_stream_si512(void* mem_addr, __m512i a);
```

Store 512-bits of integer data from *a* into memory using a non-temporal memory hint.

Intrinsics for Miscellaneous Operations

Intrinsics for Miscellaneous FP Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_fixupimm_pd, _mm512_mask_fixupimm_pd, _mm512_maskz_fixupimm_pd _mm512_fixupimm_round_pd, _mm512_mask_fixupimm_round_pd, _mm512_maskz_fixupimm_round_pd	Fixes up packed float64 elements.	VFIXUPIMMPD

`_mm_getexp_round_ss`, `_mm_mask_getexp_round_ss`, `_mm_maskz_getexp_round_ss`	Converts exponent of each scalar float32 element to a rounded scalar float32 number representing the integer exponent.	`VGETEXPSS`

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
c	third source vector element
src	source element to use based on writemask result
round	Rounding control values; these can be one of the following (along with the `sae` suppress all exceptions flag): • `_MM_FROUND_TO_NEAREST_INT` - rounds to nearest even • `_MM_FROUND_TO_NEG_INF` - rounds to negative infinity • `_MM_FROUND_TO_POS_INF` - rounds to positive infinity • `_MM_FROUND_TO_ZERO` - rounds to zero • `_MM_FROUND_CUR_DIRECTION` - rounds using default from MXCSR register
src	source element
imm	reporting flag
src	source element

_mm512_fixupimm_pd

```
extern __m512d __cdecl _mm512_fixupimm_pd(__m512d a, __m512d b, __m512i c, int imm);
```

Fixes up packed float64 elements in *a* and *b* using packed 64-bit integers in *c*, and stores the result.

imm is used to set the required flags reporting.

_mm512_mask_fixupimm_pd

```
extern __m512d __cdecl _mm512_mask_fixupimm_pd(__m512d a, __mmask8 k, __m512d b, __m512i c, int
imm);
```

Fixes up packed float64 elements in *a* and *b* using packed 64-bit integers in *c*, and stores the result using writemask *k* (elements are copied from *a* when the corresponding mask bit is not set).

imm is used to set the required flags reporting.

_mm512_maskz_fixupimm_pd

```
extern __m512d __cdecl _mm512_maskz_fixupimm_pd(__mmask8 k, __m512d a, __m512d b, __m512i c, int
imm);
```

Fixes up packed float64 elements in *a* and *b* using packed 64-bit integers in *c*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

imm is used to set the required flags reporting.

_mm512_fixupimm_round_pd

```
extern __m512d __cdecl _mm512_fixupimm_round_pd(__m512d a, __m512d b, __m512i c, int imm, int
round);
```

Fixes up packed float64 elements in *a* and *b* using packed 64-bit integers in *c*, and stores the result.

imm is used to set the required flags reporting.

_mm512_mask_fixupimm_round_pd

```
extern __m512d __cdecl _mm512_mask_fixupimm_round_pd(__m512d a, __mmask8 k, __m512d b, __m512i
c, int imm, int round);
```

Fixes up packed float64 elements in *a* and *b* using packed 64-bit integers in *c*, and stores the result using writemask *k* (elements are copied from *a* when the corresponding mask bit is not set).

imm is used to set the required flags reporting.

_mm512_maskz_fixupimm_round_pd

```
extern __m512d __cdecl _mm512_maskz_fixupimm_round_pd(__mmask8 k, __m512d a, __m512d b, __m512i
c, int imm, int round);
```

Fixes up packed float64 elements in *a* and *b* using packed 64-bit integers in *c*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

imm is used to set the required flags reporting.

_mm512_fixupimm_ps

```
extern __m512 __cdecl _mm512_fixupimm_ps(__m512 a, __m512 b, __m512i c, int imm);
```

Fixes up packed float32 elements in *a* and *b* using packed 32-bit integers in *c*, and stores the result. *imm* is used to set the required flags reporting.

_mm512_mask_fixupimm_ps

```
extern __m512 __cdecl _mm512_mask_fixupimm_ps(__m512 a, __mmask16 k, __m512 b, __m512i c, int
imm);
```

Fixes up packed float32 elements in *a* and *b* using packed 32-bit integers in *c*, and stores the result using writemask *k* (elements are copied from *a* when the corresponding mask bit is not set).

imm is used to set the required flags reporting.

_mm512_maskz_fixupimm_ps

```
extern __m512 __cdecl _mm512_maskz_fixupimm_ps(__mmask16 k, __m512 a, __m512 b, __m512i c, int
imm);
```

Fixes up packed float32 elements in *a* and *b* using packed 32-bit integers in *c*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

imm is used to set the required flags reporting.

_mm512_fixupimm_round_ps

```
extern __m512 __cdecl _mm512_fixupimm_round_ps(__m512 a, __m512 b, __m512i c, int imm, int
round);
```

Fixes up packed float32 elements in *a* and *b* using packed 32-bit integers in *c*, and stores the result. *imm* is used to set the required flags reporting.

_mm512_mask_fixupimm_round_ps

```
extern __m512 __cdecl _mm512_mask_fixupimm_round_ps(__m512 a, __mmask16 k, __m512 b, __m512i,
int imm, int round);
```

Fixes up packed float32 elements in *a* and *b* using packed 32-bit integers in *c*, and stores the result using writemask *k* (elements are copied from *a* when the corresponding mask bit is not set).

imm is used to set the required flags reporting.

_mm512_maskz_fixupimm_round_ps

```
extern __m512 __cdecl _mm512_maskz_fixupimm_round_ps(__mmask16 k, __m512 a, __m512 b, __m512i,
int imm, int round);
```

Fixes up packed float32 elements in *a* and *b* using packed 32-bit integers in *c*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

imm is used to set the required flags reporting.

_mm_fixupimm_sd

```
extern __m128d __cdecl _mm_fixupimm_sd(__m128d a, __m128d b, __m128i c, int imm);
```

Fixes up lower float64 elements in *a* and *b* using lower 64-bit integer in *c*, stores the result in lower destination element, and copies upper element from *a* to upper destination element.

imm is used to set the required flags reporting.

_mm_mask_fixupimm_sd

```
extern __m128d __cdecl _mm_mask_fixupimm_sd(__m128d a, __mmask8 k, __m128d b, __m128i c, int
imm);
```

Fixes up lower float64 elements in *a* and *b* using lower 64-bit integer in *c*, stores the result in lower destination element using writemask *k* (the element is copied from *a* when mask bit 0 is not set), and copies upper element from *a* to upper destination element.

imm is used to set the required flags reporting.

_mm_maskz_fixupimm_sd

```
extern __m128d __cdecl _mm_maskz_fixupimm_sd(__mmask8 k, __m128d a, __m128d b, __m128i c, int
imm);
```

Fixes up lower float64 elements in *a* and *b* using lower 64-bit integer in *c*, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper element from *a* to upper destination element.

imm is used to set the required flags reporting.

_mm_fixupimm_round_sd

```
extern __m128d __cdecl _mm_fixupimm_round_sd(__m128d a, __m128d b, __m128i c, int imm, int
round);
```

Fixes up lower float64 elements in *a* and *b* using lower 64-bit integer in *c*, stores the result in lower destination element, and copies upper element from *a* to upper destination element.

imm is used to set the required flags reporting.

_mm_mask_fixupimm_round_sd

```
extern __m128d __cdecl _mm_mask_fixupimm_round_sd(__m128d a, __mmask8 k, __m128d b, __m128i c,
int imm, int round);
```

Fixes up lower float64 elements in *a* and *b* using lower 64-bit integer in *c*, stores the result in lower destination element using writemask *k* (the element is copied from *a* when mask bit 0 is not set), and copies upper element from *a* to upper destination element.

imm is used to set the required flags reporting.

_mm_maskz_fixupimm_round_sd

```
extern __m128d __cdecl _mm_maskz_fixupimm_round_sd(__mmask8 k, __m128d a, __m128d b, __m128i c,
int imm, int round);
```

Fixes up lower float64 elements in *a* and *b* using lower 64-bit integer in *c*, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper element from *a* to upper destination element.

imm is used to set the required flags reporting.

_mm_fixupimm_round_ss

```
extern __m128 __cdecl _mm_fixupimm_round_ss(__m128 a, __m128 b, __m128i c, int imm, int round);
```

Fixes up lower float32 elements in *a* and *b* using lower 32-bit integer in *c*, stores the result in lower destination element, and copies upper three packed elements from *a* to upper destination elements.

imm is used to set the required flags reporting.

_mm_mask_fixupimm_round_ss

```
extern __m128 __cdecl _mm_mask_fixupimm_round_ss(__m128 a, __mmask8 k, __m128 b, __m128i c, int
imm, int round);
```

Fixes up lower float32 elements in *a* and *b* using lower 32-bit integer in *c*, stores the result in lower destination element using writemask *k* (the element is copied from *a* when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

imm is used to set the required flags reporting.

_mm_maskz_fixupimm_round_ss

```
extern __m128 __cdecl _mm_maskz_fixupimm_round_ss(__mmask8 k, __m128 a, __m128 b, __m128i c, int imm, int round);
```

Fixes up lower float32 elements in *a* and *b* using lower 32-bit integer in *c*, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

imm is used to set the required flags reporting.

_mm_fixupimm_ss

```
extern __m128 __cdecl _mm_fixupimm_ss(__m128 a, __m128 b, __m128i c, int imm);
```

Fixes up lower float32 elements in *a* and *b* using lower 32-bit integer in *c*, stores the result in lower destination element, and copies upper three packed elements from *a* to upper destination elements.

imm is used to set the required flags reporting.

_mm_mask_fixupimm_ss

```
extern __m128 __cdecl _mm_mask_fixupimm_ss(__m128 a, __mmask8 k, __m128 b, __m128i c, int imm);
```

Fixes up lower float32 elements in *a* and *b* using lower 32-bit integer in *c*, stores the result in lower destination element using writemask *k* (the element is copied from *a* when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

imm is used to set the required flags reporting.

_mm_maskz_fixupimm_ss

```
extern __m128 __cdecl _mm_maskz_fixupimm_ss(__mmask8 k, __m128 a, __m128 b, __m128i c, int imm);
```

Fixes up lower float32 elements in *a* and *b* using lower 32-bit integer in *c*, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

imm is used to set the required flags reporting.

_mm512_getexp_pd

```
extern __m512d __cdecl _mm512_getexp_pd(__m512d a);
```

Converts the exponent of each packed float64 element in *a* to a float64 number representing the integer exponent, and stores the result. This intrinsic essentially calculates `floor(log2(x))` for each element.

_mm512_mask_getexp_pd

```
extern __m512d __cdecl _mm512_mask_getexp_pd(__m512d src, __mmask8 k, __m512d a);
```

Converts the exponent of each packed float64 element in *a* to a float64 number representing the integer exponent, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set). This intrinsic essentially calculates `floor(log2(x))` for each element.

_mm512_maskz_getexp_pd

```
extern __m512d __cdecl _mm512_maskz_getexp_pd(__mmask8 k, __m512d a);
```

Converts the exponent of each packed float64 element in *a* to a float64 number representing the integer exponent, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set). This intrinsic essentially calculates `floor(log2(x))` for each element.

_mm512_getexp_round_pd

```
extern __m512d __cdecl _mm512_getexp_round_pd(__m512d a, int round);
```

Converts the exponent of each packed float64 element in *a* to a float64 number representing the integer exponent, and stores the result. This intrinsic essentially calculates `floor(log2(x))` for each element.

_mm512_mask_getexp_round_pd

```
extern __m512d __cdecl _mm512_mask_getexp_round_pd(__m512d src, __mmask8 a, __m512d, int round);
```

Converts the exponent of each packed float64 element in *a* to a float64 number representing the integer exponent, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set). This intrinsic essentially calculates `floor(log2(x))` for each element.

_mm512_maskz_getexp_round_pd

```
extern __m512d __cdecl _mm512_maskz_getexp_round_pd(__mmask8 k, __m512d a, int round);
```

Converts the exponent of each packed float64 element in *a* to a float64 number representing the integer exponent, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set). This intrinsic essentially calculates `floor(log2(x))` for each element.

_mm512_getexp_ps

```
extern __m512 __cdecl _mm512_getexp_ps(__m512 a);
```

Converts the exponent of each packed float32 element in *a* to a float32 number representing the integer exponent, and stores the result. This intrinsic essentially calculates `floor(log2(x))` for each element.

_mm512_mask_getexp_ps

```
extern __m512 __cdecl _mm512_mask_getexp_ps(__m512 src, __mmask16 k, __m512 a);
```

Converts the exponent of each packed float32 element in *a* to a float32 number representing the integer exponent, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set). This intrinsic essentially calculates `floor(log2(x))` for each element.

_mm512_maskz_getexp_ps

```
extern __m512d __cdecl _mm512_maskz_getexp_ps(__mmask16 k, __m512 a);
```

Converts the exponent of each packed float32 element in *a* to a float32 number representing the integer exponent, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set). This intrinsic essentially calculates `floor(log2(x))` for each element.

_mm512_getexp_round_ps

```
extern __m512 __cdecl _mm512_getexp_round_ps(__m512 a, int round);
```

Converts the exponent of each packed float32 element in *a* to a float32 number representing the integer exponent, and stores the result. This intrinsic essentially calculates `floor(log2(x))` for each element.

_mm512_mask_getexp_round_ps

```
extern __m512 __cdecl _mm512_mask_getexp_round_ps(__m512 src, __mmask16 k, __m512 a, int round);
```

Converts the exponent of each packed float32 element in *a* to a float32 number representing the integer exponent, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set). This intrinsic essentially calculates `floor(log2(x))` for each element.

_mm512_maskz_getexp_round_ps

```
extern __m512 __cdecl _mm512_maskz_getexp_round_ps(__mmask16 k, __m512 a, int round);
```

Converts the exponent of each packed float32 element in *a* to a float32 number representing the integer exponent, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set). This intrinsic essentially calculates `floor(log2(x))` for each element.

_mm_getexp_round_sd

```
extern __m128d __cdecl _mm_getexp_round_sd(__m128d a, __m128d b, int round);
```

Converts lower exponent of float64 element in *b* to a float64 number representing the integer exponent, stores the result in lower destination element, and copies upper element from *a* to upper destination element. This intrinsic essentially calculates `floor(log2(x))` for lower element.

_mm_mask_getexp_round_sd

```
extern __m128d __cdecl _mm_mask_getexp_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b,
int round);
```

Converts lower exponent of float64 element in *b* to a float64 number representing the integer exponent, stores the result in lower destination element, and copies upper element from *a* to upper destination element. This intrinsic essentially calculates `floor(log2(x))` for lower element.

_mm_maskz_getexp_round_sd

```
extern __m128d __cdecl _mm_maskz_getexp_round_sd(__mmask8 k, __m128d a, __m128d b, int round);
```

Converts lower exponent of float64 element in *b* to a float64 number representing the integer exponent, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper element from *a* to upper destination element. This intrinsic essentially calculates `floor(log2(x))` for lower element.

_mm_getexp_sd

```
extern __m128d __cdecl _mm_getexp_sd(__m128d a, __m128d b);
```

Converts lower exponent of float64 element in *b* to a float64 number representing the integer exponent, stores the result in lower destination element, and copies upper element from *a* to upper destination element. This intrinsic essentially calculates `floor(log2(x))` for lower element.

_mm_mask_getexp_sd

```
extern __m128d __cdecl _mm_mask_getexp_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
```

Converts lower exponent of float64 element in *b* to a float64 number representing the integer exponent, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper element from *a* to upper destination element. This intrinsic essentially calculates `floor(log2(x))` for lower element.

_mm_maskz_getexp_sd

```
extern __m128d __cdecl _mm_maskz_getexp_sd(__mmask8 k, __m128d a, __m128d b);
```

Converts lower exponent of float64 element in *b* to a float64 number representing the integer exponent, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper element from *a* to upper destination element. This intrinsic essentially calculates `floor(log2(x))` for lower element.

_mm_getexp_round_ss

```
extern __m128 __cdecl _mm_getexp_round_ss(__m128 a, __m128 b, int round);
```

Converts lower exponent of float32 element in *b* to a float32 number representing the integer exponent, stores the result in lower destination element, and copies upper three packed elements from *a* to upper destination elements. This intrinsic essentially calculates `floor(log2(x))` for lower element.

_mm_mask_getexp_round_ss

```
extern __m128 __cdecl _mm_mask_getexp_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b, int
round);
```

Converts lower exponent of float32 element in *b* to a float32 number representing the integer exponent, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper three packed elements from *a* to upper elements. This intrinsic essentially calculates `floor(log2(x))` for lower element.

_mm_maskz_getexp_round_ss

```
extern __m128 __cdecl _mm_maskz_getexp_round_ss(__mmask8 k, __m128 a, __m128 b, int round);
```

Converts lower exponent of float32 element in *b* to a float32 number representing the integer exponent, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper three packed elements from *a* to upper elements. This intrinsic essentially calculates `floor(log2(x))` for lower element.

_mm_getexp_ss

```
extern __m128 __cdecl _mm_getexp_ss(__m128 a, __m128 b);
```

Converts lower exponent of float32 element in *b* to a float32 number representing the integer exponent, stores the result in lower destination element, and copies upper three packed elements from *a* to upper destination elements. This intrinsic essentially calculates `floor(log2(x))` for lower element.

_mm_mask_getexp_ss

```
extern __m128 __cdecl _mm_mask_getexp_ss(__m128 src, __mmask8 k, __m128 a, __m128b);
```

Converts lower exponent of float32 element in *b* to a float32 number representing the integer exponent, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements. This intrinsic essentially calculates `floor(log2(x))` for lower element.

_mm_maskz_getexp_ss

```
extern __m128 __cdecl _mm_maskz_getexp_ss(__mmask8 k, __m128 a, __m128 b);
```

Converts lower exponent of float32 element in *b* to a float32 number representing the integer exponent, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements. This intrinsic essentially calculates `floor(log2(x))` for lower element.

Intrinsics for Miscellaneous Integer Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_alignr_epi32`, `_mm512_mask_alignr_epi32`, `_mm512_maskz_alignr_epi32`	Aligns elements of two source vectors depending on bits in a mask.	`VALIGND`
`_mm512_alignr_epi64`, `_mm512_mask_alignr_epi64`, `_mm512_maskz_alignr_epi64`	Aligns elements of two source vectors depending on bits in a mask.	`VALIGNQ`

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result
count	specifies the number of bits for shift operation

_mm512_alignr_epi32

```
extern __m512i __cdecl _mm512_alignr_epi32(__m512i a, __m512i b, const int count);
```

Concatenates vector elements from *a* and *b* into a 128-byte immediate result, shifts the result right by *count* of 32-bit elements, and stores the low 64 bytes (sixteen elements).

_mm512_mask_alignr_epi32

```
extern __m512i __cdecl _mm512_mask_alignr_epi32(__m512i src, __mmask16 k, __m512i a, __m512i b,
const int count);
```

Concatenates vector elements from *a* and *b* into a 128-byte immediate result, shifts the result right by *count* of 32-bit elements, and stores the low 64 bytes (sixteen elements) using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_alignr_epi32

```
extern __m512i __cdecl _mm512_maskz_alignr_epi32(__mmask16 k, __m512i a, __m512i b, const int
count);
```

Concatenates vector elements from *a* and *b* into a 128-byte immediate result, shifts the result right by *count* of 32-bit elements, and stores the low 64 bytes (sixteen elements) using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_alignr_epi64

```
extern __m512i __cdecl _mm512_alignr_epi64(__m512i a, __m512i b, const int count);
```

Concatenates vector elements from *a* and *b* into a 128-byte immediate result, shifts the result right by *count* of 64-bit elements, and stores the low 64 bytes (eight elements).

_mm512_mask_alignr_epi64

```
extern __m512i __cdecl _mm512_mask_alignr_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b,
const int count);
```

Concatenates vector elements from *a* and *b* into a 128-byte immediate result, shifts the result right by *count* of 64-bit elements, and stores the low 64 bytes (eight elements) using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_alignr_epi64

```
extern __m512i __cdecl _mm512_maskz_alignr_epi64(__mmask8 k, __m512i a, __m512i b, const int
count);
```

Concatenates vector elements from *a* and *b* into a 128-byte immediate result, shifts the result right by *count* of 64-bit elements, and stores the low 64 bytes (eight elements) using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Move Operations

Intrinsics for FP Move Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_mask_mov_pd`, `_mm512_maskz_mov_pd`	Moves packed float64 elements.	`VMOVAPD`
`_mm512_mask_mov_ps`, `_mm512_maskz_mov_ps`	Moves packed float32 elements.	`VMOVAPS`

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm_mask_move_sd`, `_mm_maskz_move_sd`	Moves scalar float64 elements.	VMOVSD
`_mm_mask_move_ss`, `_mm_maskz_move_ss`	Moves scalar float32 elements.	VMOVSS
`_mm512_movedup_pd`, `_mm512_mask_movedup_pd`, `_mm512_maskz_movedup_pd`	Duplicates even-indexed float64 elements.	VMOVDDUP
`_mm512_movehdup_ps`, `_mm512_mask_movehdup_ps`, `_mm512_maskz_movehdup_ps`	Duplicates odd-indexed float32 elements.	VMOVSHDUP
`_mm512_moveldup_ps`, `_mm512_mask_moveldup_ps`, `_mm512_maskz_moveldup_ps`	Moves lower float32 element.	VMOVSLDUP

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result

_mm512_mask_mov_pd

```
extern __m512d __cdecl _mm512_mask_mov_pd(__m512d src, __mmask8 k, __m512d a);
```

Moves packed float64 elements from *a* using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_mov_pd

```
extern __m512d __cdecl _mm512_maskz_mov_pd(__mmask8 k, __m512d a);
```

Moves packed float64 elements from *a* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mask_mov_ps

```
extern __m512 __cdecl _mm512_mask_mov_ps(__m512 src, __mmask16 k, __m512 a);
```

Moves packed float32 elements from *a* using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_mov_ps

```
extern __m512 __cdecl _mm512_maskz_mov_ps(__mmask16 k, __m512 a);
```

Moves packed float32 elements from *a* using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_movedup_pd

```
extern __m512d __cdecl _mm512_movedup_pd(__m512d a);
```

Duplicates even-indexed float64 elements from *a*, and stores the result.

_mm512_mask_movedup_pd

```
extern __m512d __cdecl _mm512_mask_movedup_pd(__m512d src, __mmask8 k, __m512d a);
```

Duplicates even-indexed float64 elements from *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_movedup_pd

```
extern __m512d __cdecl _mm512_maskz_movedup_pd(__mmask8 k, __m512d a);
```

Duplicates even-indexed float64 elements from *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_move_sd

```
extern __m128d __cdecl _mm_mask_move_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
```

Moves lower float64 element from *b* to lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copy upper element from *a* to upper destination element.

_mm_maskz_move_sd

```
extern __m128d __cdecl _mm_maskz_move_sd(__mmask8 k, __m128d a, __m128d b);
```

Moves lower float64 element from *b* to lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copy upper element from *a* to upper destination element.

_mm512_movehdup_ps

```
extern __m512 __cdecl _mm512_movehdup_ps(__m512 a);
```

Duplicates odd-indexed float32 elements from *a*, and stores the result.

_mm512_mask_movehdup_ps

```
extern __m512 __cdecl _mm512_mask_movehdup_ps(__m512 src, __mmask16 k, __m512 a);
```

Duplicates odd-indexed float32 elements from *a*, and store the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_movehdup_ps

```
extern __m512 __cdecl _mm512_maskz_movehdup_ps(__mmask16 k, __m512 a);
```

Duplicates odd-indexed float32 elements from *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_moveldup_ps

```
extern __m512 __cdecl _mm512_moveldup_ps(__m512 a);
```

Duplicates even-indexed float32 elements from *a*, and stores the result.

_mm512_mask_moveldup_ps

```
extern __m512 __cdecl _mm512_mask_moveldup_ps(__m512 src, __mmask16 k, __m512 a);
```

Duplicates even-indexed float32 elements from *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_moveldup_ps

```
extern __m512 __cdecl _mm512_maskz_moveldup_ps(__mmask16 k, __m512 a);
```

Duplicates even-indexed float32 elements from *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_move_ss

```
extern __m128 __cdecl _mm_mask_move_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);
```

Moves lower float32 element from *b* to lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

_mm_maskz_move_ss

```
extern __m128 __cdecl _mm_maskz_move_ss(__mmask8 k, __m128 a, __m128 b);
```

Moves lower float32 element from *b* to lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

Intrinsics for Integer Move Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_mask_mov_epi32, _mm512_maskz_mov_epi32	Move packed int32 elements.	VMOVDQA32
_mm512_mask_mov_epi64, _mm512_maskz_mov_epi64	Move packed int64 elements.	VMOVQA64

variable	definition
k	writemask used as a selector
a	first source vector element
src	source element to use based on writemask result

_mm512_mask_mov_epi32

```
extern __m512i __cdecl _mm512_mask_mov_epi32(__m512i a, __mmask16 k, __m512i src);
```

Move packed int32 elements from *a* to destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_mov_epi32

```
extern __m512i __cdecl _mm512_maskz_mov_epi32(__mmask16 k, __m512i a);
```

Move packed int32 elements from *a* to destination using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_mask_mov_epi64

```
extern __m512i __cdecl _mm512_mask_mov_epi64(__m512i a, __mmask16 k, __m512i src);
```

Move packed int64 elements from *a* to destination using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_mov_epi64

```
extern __m512i __cdecl _mm512_maskz_mov_epi64(__mmask8 k, __m512i a);
```

Move packed int64 elements from *a* to destination using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Pack and Unpack Operations

Intrinsics for FP Pack and Unpack Operations

The prototypes for Intel© Advanced Vector Extensions 512 (Intel© AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_unpackhi_pd, _mm512_mask_unpackhi_pd, _mm512_maskz_unpackhi_pd	Unpacks and interleaves high packed float64 values.	VPUNPCKHPD
_mm512_unpackhi_ps, _mm512_mask_unpackhi_ps, _mm512_maskz_unpackhi_ps	Unpacks and interleaves high packed float32 values.	VPUNPCKHPS
_mm512_unpacklo_pd, _mm512_mask_unpacklo_pd, _mm512_maskz_unpacklo_pd	Unpacks and interleaves low packed float64 values.	VPUNPCKLPD
_mm512_unpacklo_ps, _mm512_mask_unpacklo_ps, _mm512_maskz_unpacklo_ps	Unpacks and interleaves low packed float32 values.	VPUNPCKLPS

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result

_mm512_unpackhi_pd

```
extern __m512d __cdecl _mm512_unpackhi_pd(__m512d a, __m512d b);
```

Unpacks and interleaves float64 elements from the high half of each 128-bit lane in *a* and *b*, and stores the result.

_mm512_mask_unpackhi_pd

```
extern __m512d __cdecl _mm512_mask_unpackhi_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
```

Unpacks and interleaves float64 elements from the high half of each 128-bit lane in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_unpackhi_pd

```
extern __m512d __cdecl _mm512_maskz_unpackhi_pd(__mmask8 k, __m512d a, __m512d b);
```

Unpacks and interleaves float64 elements from the high half of each 128-bit lane in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_unpackhi_ps

```
extern __m512 __cdecl _mm512_unpackhi_ps(__m512 a, __m512 b);
```

Unpacks and interleaves float32 elements from the high half of each 128-bit lane in *a* and *b*, and stores the result.

_mm512_mask_unpackhi_ps

```
extern __m512 __cdecl _mm512_mask_unpackhi_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);
```

Unpacks and interleaves float32 elements from the high half of each 128-bit lane in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_unpackhi_ps

```
extern __m512 __cdecl _mm512_maskz_unpackhi_ps(__mmask16 k, __m512 a, __m512 b);
```

Unpacks and interleaves float32 elements from the high half of each 128-bit lane in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_unpacklo_pd

```
extern __m512d __cdecl _mm512_unpacklo_pd(__m512d a, __m512d b);
```

Unpacks and interleaves float64 elements from the low half of each 128-bit lane in *a* and *b*, and stores the result.

_mm512_mask_unpacklo_pd

```
extern __m512d __cdecl _mm512_mask_unpacklo_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
```

Unpacks and interleaves float64 elements from the low half of each 128-bit lane in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_unpacklo_pd

```
extern __m512d __cdecl _mm512_maskz_unpacklo_pd(__mmask8 k, __m512d a, __m512d b);
```

Unpacks and interleaves float64 elements from the low half of each 128-bit lane in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_unpacklo_ps

```
extern __m512 __cdecl _mm512_unpacklo_ps(__m512 a, __m512 b);
```

Unpacks and interleaves float32 elements from the low half of each 128-bit lane in *a* and *b*, and stores the result.

_mm512_mask_unpacklo_ps

```
extern __m512 __cdecl _mm512_mask_unpacklo_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);
```

Unpacks and interleaves float32 elements from the low half of each 128-bit lane in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_unpacklo_ps

```
extern __m512 __cdecl _mm512_maskz_unpacklo_ps(__mmask16 k, __m512 a, __m512 b);
```

Unpacks and interleaves float32 elements from the low half of each 128-bit lane in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Integer Pack and Unpack Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_unpackhi_epi32`, `_mm512_mask_unpackhi_epi32`, `_mm512_maskz_unpackhi_epi32`	Unpacks and interleaves high packed int32 values.	`VPUNPCKHQD`, `VUNPCKHQD`, `UNPCKHQD`
`_mm512_unpackhi_epi64`, `_mm512_mask_unpackhi_epi64`, `_mm512_maskz_unpackhi_epi64`	Unpacks and interleaves high packed int64 values.	`VPUNPCKHQDQ`, `VUNPCKHQDQ`, `UNPCKHQDQ`

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_unpacklo_epi32`, `_mm512_mask_unpacklo_epi32`, `_mm512_maskz_unpacklo_epi32`	Unpacks and interleaves low packed int32 values.	`VPUNPCKLQD`, `VUNPCKLQD`, `UNPCKLQD`
`_mm512_unpacklo_epi64`, `_mm512_mask_unpacklo_epi64`, `_mm512_maskz_unpacklo_epi64`	Unpacks and interleaves low packed int64 values.	`VPUNPCKLQDQ`, `VUNPCKLQDQ`, `UNPCKLQDQ`

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result

_mm512_unpackhi_epi32

```
extern __m512i __cdecl _mm512_unpackhi_epi32(__m512i a, __m512i b);
```

Unpacks and interleaves int32 elements from the high half of each 128-bit lane in *a* and *b*, and stores the result.

_mm512_mask_unpackhi_epi32

```
extern __m512i __cdecl _mm512_mask_unpackhi_epi32(__m512i src, __mmask16 k, __m512i a, __m512i
b);
```

Unpacks and interleaves int32 elements from the high half of each 128-bit lane in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_unpackhi_epi32

```
extern __m512i __cdecl _mm512_maskz_unpackhi_epi32(__mmask16 k, __m512i a, __m512i b);
```

Unpacks and interleaves int32 elements from the high half of each 128-bit lane in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_unpackhi_epi64

```
extern __m512i __cdecl _mm512_unpackhi_epi64(__m512i a, __m512i b);
```

Unpacks and interleaves int64 elements from the high half of each 128-bit lane in *a* and *b*, and stores the result.

_mm512_mask_unpackhi_epi64

```
extern __m512i __cdecl _mm512_mask_unpackhi_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
```

Unpacks and interleaves int64 elements from the high half of each 128-bit lane in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_unpackhi_epi64

```
extern __m512i __cdecl _mm512_maskz_unpackhi_epi64(__mmask8 k, __m512i a, __m512i b);
```

Unpacks and interleaves int64 elements from the high half of each 128-bit lane in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_unpacklo_epi32

```
extern __m512i __cdecl _mm512_unpacklo_epi32(__m512i a, __m512i b);
```

Unpacks and interleaves int32 elements from the low half of each 128-bit lane in *a* and *b*, and stores the result.

_mm512_mask_unpacklo_epi32

```
extern __m512i __cdecl _mm512_mask_unpacklo_epi32(__m512i src, __mmask16 k, __m512i a, __m512i
b);
```

Unpacks and interleaves int32 elements from the low half of each 128-bit lane in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_unpacklo_epi32

```
extern __m512i __cdecl _mm512_maskz_unpacklo_epi32(__mmask16 k, __m512i a, __m512i b);
```

Unpacks and interleaves int32 elements from the low half of each 128-bit lane in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_unpacklo_epi64

```
extern __m512i __cdecl _mm512_unpacklo_epi64(__m512i a, __m512i b);
```

Unpacks and interleaves int64 elements from the low half of each 128-bit lane in *a* and *b*, and stores the result.

_mm512_mask_unpacklo_epi64

```
extern __m512i __cdecl _mm512_mask_unpacklo_epi64(__m512i src, __mmask8 k, __m512i a, __m512i b);
```

Unpacks and interleaves int64 elements from the low half of each 128-bit lane in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_unpacklo_epi64

```
extern __m512i __cdecl _mm512_maskz_unpacklo_epi64(__mmask8 k, __m512i a, __m512i b);
```

Unpacks and interleaves int64 elements from the low half of each 128-bit lane in *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Permutation Operations

Intrinsics for FP Permutation Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_permutex2var_pd, _mm512_mask_permutex2var_pd, _mm512_mask2_permutex2var_pd, _mm512_maskz_permutex2var_pd	Shuffle float64 elements across lanes.	VPERMI2PD
_mm512_permutex2var_ps, _mm512_mask_permutex2var_ps, _mm512_mask2_permutex2var_ps, _mm512_maskz_permutex2var_ps	Shuffle float32 elements across lanes.	VPERMI2PS

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result
idx	index

variable	definition

_mm512_permutex2var_pd

```
extern __m512d __cdecl _mm512_permutex2var_pd(__m512d a, __m512i idx, __m512d b);
```

Shuffles float64 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result.

_mm512_mask_permutex2var_pd

```
extern __m512d __cdecl _mm512_mask_permutex2var_pd(__m512d a, __mmask8 k, __m512i idx, __m512d
b);
```

Shuffles float64 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result using writemask *k* (elements are copied from *a* when the corresponding mask bit is not set).

_mm512_mask2_permutex2var_pd

```
extern __m512d __cdecl _mm512_mask2_permutex2var_pd(__m512d a, __m512i idx, __mmask8 k, __m512d
b);
```

Shuffles float64 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the results using writemask *k* (elements are copied from *idx* when the corresponding mask bit is not set)

_mm512_maskz_permutex2var_pd

```
extern __m512d __cdecl _mm512_maskz_permutex2var_pd(__mmask8 k, __m512d a, __m512i idx, __m512d
b);
```

Shuffles float64 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permutex2var_ps

```
extern __m512 __cdecl _mm512_permutex2var_ps(__m512 a, __m512i idx, __m512 b);
```

Shuffles float32 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result.

_mm512_mask2_permutex2var_ps

```
extern __m512 __cdecl _mm512_mask_permutex2var_ps(__m512 a, __mmask16 k, __m512i idx, __m512 b);
```

Shuffles float32 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result using writemask *k* (elements are copied from *idx* when the corresponding mask bit is not set).

_mm512_mask_permutex2var_ps

```
extern __m512 __cdecl _mm512_mask2_permutex2var_ps(__m512 a, __m512i idx, __mmask16 k, __m512 b);
```

Shuffles float32 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result using writemask *k* (elements are copied from *a* when the corresponding mask bit is not set).

_mm512_maskz_permutex2var_ps

```
extern __m512 __cdecl _mm512_maskz_permutex2var_ps(__mmask16 k, __m512 a, __m512i idx, __m512 b);
```

Shuffles float32 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permute_pd

```
extern __m512d __cdecl _mm512_permute_pd(__m512d a, const int imm);
```

Shuffles float64 elements in *a* within 128-bit lanes using the control in *imm*, and stores the result.

_mm512_mask_permute_pd

```
extern __m512d __cdecl _mm512_mask_permute_pd(__m512d src, __mmask8 k, __m512d a, const int imm);
```

Shuffles float64 elements in *a* within 128-bit lanes using the control in *imm*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_permute_pd

```
extern __m512d __cdecl _mm512_maskz_permute_pd(__mmask8 k, __m512d a, const int imm);
```

Shuffles float64 elements in *a* within 128-bit lanes using the control in *imm*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permutevar_pd

```
extern __m512d __cdecl _mm512_permutevar_pd(__m512d a, __m512i b);
```

Shuffles float64 elements in *a* within 128-bit lanes using the control in *b*, and stores the result.

_mm512_mask_permutevar_pd

```
extern __m512d __cdecl _mm512_mask_permutevar_pd(__m512d src, __mmask8 k, __m512d a, __m512i b);
```

Shuffles float64 elements in *a* within 128-bit lanes using the control in *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_permutevar_pd

```
extern __m512d __cdecl _mm512_maskz_permutevar_pd(__mmask8 k, __m512d a, __m512i b);
```

Shuffles float64 elements in *a* within 128-bit lanes using the control in *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permute_ps

```
extern __m512 __cdecl _mm512_permute_ps(__m512 a, const int imm);
```

Shuffles float32 elements in *a* within 128-bit lanes using the control in *imm*, and stores the result.

_mm512_mask_permute_ps

```
extern __m512 __cdecl _mm512_mask_permute_ps(__m512 src, __mmask16 k, __m512 a, const int imm);
```

Shuffles float32 elements in *a* within 128-bit lanes using the control in *imm*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_permute_ps

```
extern __m512 __cdecl _mm512_maskz_permute_ps(__mmask16 k, __m512 a, const int imm);
```

Shuffles float32 elements in *a* within 128-bit lanes using the control in *imm*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permutevar_ps

```
extern __m512 __cdecl _mm512_permutevar_ps(__m512 a, __m512i b);
```

Shuffles float32 elements in *a* within 128-bit lanes using the control in *b*, and stores the result.

_mm512_mask_permutevar_ps

```
extern __m512 __cdecl _mm512_mask_permutevar_ps(__m512 src, __mmask16 k, __m512 a, __m512i b);
```

Shuffles float32 elements in *a* within 128-bit lanes using the control in *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_permutevar_ps

```
extern __m512 __cdecl _mm512_maskz_permutevar_ps(__mmask16 k, __m512 a, __m512i b);
```

Shuffles float32 elements in *a* within 128-bit lanes using the control in *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permutex_pd

```
extern __m512d __cdecl _mm512_permutex_pd(__m512d a, const int imm);
```

Shuffles float64 elements in *a* within 256-bit lanes using the control in *imm*, and stores the result.

_mm512_mask_permutex_pd

```
extern __m512d __cdecl _mm512_mask_permutex_pd(__m512d src, __mmask8 k, __m512d a, const int
imm);
```

Shuffles float64 elements in *a* within 256-bit lanes using the control in *imm*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_permutex_pd

```
extern __m512d __cdecl _mm512_maskz_permutex_pd(__mmask8 k, __m512d a, const int imm);
```

Shuffles float64 elements in *a* within 256-bit lanes using the control in *imm*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permutexvar_pd

```
extern __m512d __cdecl _mm512_permutexvar_pd(__m512i idx, __m512d a);
```

Shuffles float64 elements in *a* across lanes using the corresponding index in *idx*, and stores the result.

_mm512_mask_permutexvar_pd

```
extern __m512d __cdecl _mm512_mask_permutexvar_pd(__m512d src, __mmask8 k, __m512i idx, __m512d
a);
```

Shuffles float64 elements in *a* across lanes using the corresponding index in *idx*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_permutexvar_pd

```
extern __m512d __cdecl _mm512_maskz_permutexvar_pd(__mmask8 k, __m512i idx, __m512d a);
```

Shuffles float64 elements in *a* across lanes using the corresponding index in *idx*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permutexvar_ps

```
extern __m512 __cdecl _mm512_permutexvar_ps(__m512i idx, __m512 a);
```

Shuffles float32 elements in *a* across lanes using the corresponding index in *idx*, and stores the result.

_mm512_mask_permutexvar_ps

```
extern __m512 __cdecl _mm512_mask_permutexvar_ps(__m512 src, __mmask16 k, __m512i idx, __m512 a);
```

Shuffles float32 elements in *a* across lanes using the corresponding index in *idx*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_permutexvar_ps

```
extern __m512 __cdecl _mm512_maskz_permutexvar_ps(__mmask16 k, __m512i idx, __m512 a);
```

Shuffles float32 elements in *a* across lanes using the corresponding index in *idx*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Integer Permutation Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_permutex2var_epi32`, `_mm512_mask_permutex2var_epi32`, `_mm512_mask2_permutex2var_epi32`, `_mm512_maskz_permutex2var_epi32`	Shuffle int32 elements across lanes.	`VPERMI2D`
`_mm512_permutex2var_epi64`, `_mm512_mask_permutex2var_epi64`, `_mm512_mask2_permutex2var_epi64`, `_mm512_maskz_permutex2var_epi64`	Shuffle int64 elements across lanes.	`VPERMI2Q`, `VPERMT2Q`

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction

`_mm512_permutevar_epi32`, `_mm512_mask_permutevar_epi32`
 	
`_mm512_permutexvar_epi32`, `_mm512_mask_permutexvar_epi32`, `_mm512_maskz_permutexvar_epi32`
	Shuffle int32 elements across lanes.	`VPERMD`

`_mm512_permutex_epi64`, `_mm512_mask_permutex_epi64`, `_mm512_maskz_permutex_epi64`
 	
`_mm512_permutexvar_epi64`, `_mm512_mask_permutexvar_epi64`, `_mm512_maskz_permutexvar_epi64`
	Shuffle int64 elements across lanes.	`VPERMQ`

variable	definition
k	writemask used as a selector
a	first source vector element
src	source element to use based on writemask result
idx	int32 vector containing indices in memory

_mm512_permutevar_epi32

```
extern __m512i __cdecl _mm512_permutevar_epi32(__m512i a, __m512i idx);
```

Shuffle int32 elements in *a* across lanes using the corresponding index in *idx*, and stores the result.

> **NOTE**
> This intrinsic shuffles across 128-bit lanes, unlike past intrinsics that use the `permutevar` name. This intrinsic is identical to `_mm512_mask_permutexvar_epi32`, and it is recommended that you use that intrinsic name.

_mm512_mask_permutevar_epi32

```
extern __m512i __cdecl _mm512_mask_permutevar_epi32(__m512i src, __mmask16 k, __m512i a, __m512i
idx);
```

Shuffle int32 elements in *a* across lanes using the corresponding index in *idx*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

NOTE
This intrinsic shuffles across 128-bit lanes, unlike past intrinsics that use the `permutevar` name. This intrinsic is identical to `_mm512_mask_permutexvar_epi32`, and it is recommended that you use that intrinsic name.

_mm512_permutexvar_epi32

```
extern __m512i __cdecl _mm512_permutexvar_epi32(__m512i idx, __m512i a);
```

Shuffles int32 elements in *a* across lanes using the corresponding index in *idx*, and stores the result.

_mm512_mask_permutexvar_epi32

```
extern __m512i __cdecl _mm512_mask_permutexvar_epi32(__m512i src, __mmask16 k, __m512i idx,
__m512i a);
```

Shuffles int32 elements in *a* across lanes using the corresponding index in *idx*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_permutexvar_epi32

```
extern __m512i __cdecl _mm512_maskz_permutexvar_epi32(__mmask16 k, __m512i idx, __m512i a);
```

Shuffles int32 elements in *a* across lanes using the corresponding index in *idx*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permutex2var_epi32

```
extern __m512i __cdecl _mm512_permutex2var_epi32(__m512i a, __m512i idx, __m512i b);
```

Shuffles int32 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result.

_mm512_mask_permutex2var_epi32

```
extern __m512i __cdecl _mm512_mask_permutex2var_epi32(__m512i a, __mmask16 k, __m512i idx,
__m512i b);
```

Shuffles int32 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result using writemask *k* (elements are copied from *a* when the corresponding mask bit is not set).

_mm512_mask2_permutex2var_epi32

```
extern __m512i __cdecl _mm512_mask2_permutex2var_epi32(__m512i a, __m512i idx, __mmask16 k,
__m512i b);
```

Shuffles int32 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result using writemask *k* (elements are copied from *idx* when the corresponding mask bit is not set).

_mm512_maskz_permutex2var_epi32

```
extern __m512i __cdecl _mm512_maskz_permutex2var_epi32(__mmask16 k, __m512i a, __m512i idx,
__m512i b);
```

Shuffles int32 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permutex2var_epi64

```
extern __m512i __cdecl _mm512_permutex2var_epi64(__m512i a, __m512i idx, __m512i b);
```

Shuffles int64 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result.

_mm512_mask_permutex2var_epi64

```
extern __m512i __cdecl _mm512_mask_permutex2var_epi64(__m512i a, __mmask8 k, __m512i idx,
__m512i b);
```

Shuffles int64 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result using writemask *k* (elements are copied from *a* when the corresponding mask bit is not set).

_mm512_mask2_permutex2var_epi64

```
extern __m512i __cdecl _mm512_mask2_permutex2var_epi64(__m512i a, __m512i idx, __mmask8 k,
__m512i b);
```

Shuffles int64 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result using writemask *k* (elements are copied from *idx* when the corresponding mask bit is not set).

_mm512_maskz_permutex2var_epi64

```
extern __m512i __cdecl _mm512_maskz_permutex2var_epi64(__mmask8 k, __m512i a, __m512i idx,
__m512i b);
```

Shuffles int64 elements in *a* and *b* across lanes using the corresponding selector and index in *idx*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permutex_epi64

```
extern __m512i __cdecl _mm512_permutex_epi64(__m512i a, const int imm);
```

Shuffles int64 elements in *a* within 256-bit lanes using the control in *imm*, and stores the result.

_mm512_mask_permutex_epi64

```
extern __m512i __cdecl _mm512_mask_permutex_epi64(__m512i src, __mmask8 k, __m512i a, const int
imm);
```

Shuffles int64 elements in *a* within 256-bit lanes using the control in *imm*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_permutex_epi64

```
extern __m512i __cdecl _mm512_maskz_permutex_epi64(__mmask8 k, __m512i a, const int imm);
```

Shuffles int64 elements in *a* within 256-bit lanes using the control in *imm*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_permutexvar_epi64

```
extern __m512i __cdecl _mm512_permutexvar_epi64(__m512i idx, __m512i a);
```

Shuffles int64 elements in *a* across lanes using the corresponding index *idx*, and stores the result.

_mm512_mask_permutexvar_epi64

```
extern __m512i __cdecl _mm512_mask_permutexvar_epi64(__m512i src, __mmask8 k, __m512i idx,
__m512i a);
```

Shuffles int64 elements in *a* across lanes using the corresponding index *idx*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_permutexvar_epi64

```
extern __m512i __cdecl _mm512_maskz_permutexvar_epi64(__mmask8 k, __m512i idx, __m512i a);
```

Shuffles int64 elements in *a* across lanes using the corresponding index *idx*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Reduction Operations

Intrinsics for FP Reduction Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_reduce_add_pd`, `_mm512_mask_reduce_add_pd`	Reduce float64 elements by addition.	**None.**
`_mm512_reduce_add_ps`, `_mm512_mask_reduce_add_ps`	Reduce float32 elements by addition.	**None.**
`_mm512_reduce_max_pd`, `_mm512_mask_reduce_max_pd`	Reduce float64 elements by maximum.	**None.**
`_mm512_reduce_max_ps`, `_mm512_mask_reduce_max_ps`	Reduce float32 elements by maximum.	**None.**
`_mm512_reduce_min_pd`, `_mm512_mask_reduce_min_pd`	Reduce float64 elements by minimum.	**None.**
`_mm512_reduce_min_ps`, `_mm512_mask_reduce_min_ps`	Reduce float32 elements by minimum.	**None.**
`_mm512_reduce_mul_pd`, `_mm512_mask_reduce_mul_pd`	Reduce float64 elements by multiplication.	**None.**
`_mm512_reduce_mul_ps`, `_mm512_mask_reduce_mul_ps`	Reduce float32 elements by multiplication.	**None.**

variable	definition
k	writemask

variable	definition
a	first source vector element

_mm512_reduce_add_pd

```
extern double __cdecl _mm512_reduce_add_pd(__m512d a);
```

Reduces packed float64 elements in *a* by addition.

Returns the sum of all elements in *a*.

_mm512_mask_reduce_add_pd

```
extern double __cdecl _mm512_mask_reduce_add_pd(__mmask8 k, __m512d a);
```

Reduces packed float64 elements in *a* by addition using writemask *k*.

Returns the sum of all active elements in *a*.

_mm512_reduce_add_ps

```
extern float __cdecl _mm512_reduce_add_ps(__m512 a);
```

Reduces packed float32 elements in *a* by addition.

Returns the sum of all elements in *a*.

_mm512_mask_reduce_add_ps

```
extern float __cdecl _mm512_mask_reduce_add_ps(__mmask16 k, __m512 a);
```

Reduces packed float32 elements in *a* by addition using writemask *k*.

Returns the sum of all active elements in *a*.

_mm512_reduce_max_pd

```
extern double __cdecl _mm512_reduce_max_pd(__m512d a);
```

Reduces packed float64 elements in *a* by maximum.

Returns the maximum of all elements in *a*.

_mm512_mask_reduce_max_pd

```
extern double __cdecl _mm512_mask_reduce_max_pd(__mmask8 k, __m512d a);
```

Reduces packed float64 elements in *a* by maximum, using writemask *k*.

Returns the maximum of all active elements in *a*.

_mm512_reduce_max_ps

```
extern float __cdecl _mm512_reduce_max_ps(__m512 a);
```

Reduces packed float32 elements in *a* by maximum.

Returns the maximum of all elements in *a*.

_mm512_mask_reduce_max_ps

```
extern float __cdecl _mm512_mask_reduce_max_ps(__mmask16 k, __m512 a);
```

Reduces packed float32 elements in *a* by maximum, using writemask *k*.

Returns the maximum of all active elements in *a*.

_mm512_reduce_min_pd

```
extern double __cdecl _mm512_reduce_min_pd(__m512d a);
```

Reduces packed float64 elements in *a* by minimum.

Returns the minimum of all elements in *a*.

_mm512_mask_reduce_min_pd

```
extern double __cdecl _mm512_mask_reduce_min_pd(__mmask8 k, __m512d a);
```

Reduces packed float64 elements in *a* by minimum, using writemask *k*.

Returns the minimum of all active elements in *a*.

_mm512_reduce_min_ps

```
extern float __cdecl _mm512_reduce_min_ps(__m512 a);
```

Reduces packed float32 elements in *a* by minimum.

Returns the minimum of all elements in *a*.

_mm512_mask_reduce_min_ps

```
extern float __cdecl _mm512_mask_reduce_min_ps(__mmask16 k, __m512 a);
```

Reduces packed float32 elements in *a* by minimum, using writemask *k*.

Returns the minimum of all active elements in *a*.

_mm512_reduce_mul_pd

```
extern double __cdecl _mm512_reduce_mul_pd(__m512d a);
```

Reduces packed float64 elements in *a* by multiplication.

Returns the product of all elements in *a*.

_mm512_mask_reduce_mul_pd

```
extern double __cdecl _mm512_mask_reduce_mul_pd(__mmask8 k, __m512d a);
```

Reduces packed float64 elements in *a* by multiplication, using writemask *k*.

Returns the product of all active elements in *a*.

_mm512_reduce_mul_ps

```
extern float __cdecl _mm512_reduce_mul_ps(__m512 a);
```

Reduces packed float32 elements in *a* by multiplication.

Returns the product of all elements in *a*.

_mm512_mask_reduce_mul_ps

```
extern float __cdecl _mm512_mask_reduce_mul_ps(__mmask16 k, __m512 a);
```

Reduces packed float32 elements in *a* by multiplication, using writemask *k*.

Returns the product of all active elements in *a*.

Intrinsics for Integer Reduction Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_reduce_add_epi32`, `_mm512_mask_reduce_add_epi32`	Reduces int32 elements of an addition operation.	**None.**
`_mm512_reduce_add_epi64`, `_mm512_mask_reduce_add_epi64`	Reduces int64 elements of an addition operation.	**None.**
`_mm512_reduce_mul_epi32`, `_mm512_mask_reduce_mul_epi32`	Reduces int32 elements of a multiplication operation.	**None.**

`_mm512_reduce_or_epi32`, `_mm512_mask_reduce_or_epi32`	Reduces int32 elements of a bitwise `OR` operation.	**None.**

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_reduce_or_epi64`, `_mm512_mask_reduce_or_epi64`	Reduces int64 elements of a bitwise `OR` operation.	**None.**
`_mm512_reduce_and_epi32`, `_mm512_mask_reduce_and_epi32`	Reduces int32 elements of a bitwise `AND` operation.	**None.**
`_mm512_reduce_and_epi64`, `_mm512_mask_reduce_and_epi64`	Reduces int64 elements of a bitwise `AND` operation.	**None.**

variable	definition
k	writemask used as a selector
a	first source vector element
src	source element to use based on writemask result

_mm512_reduce_and_epi32

```
extern int __cdecl _mm512_reduce_and_epi32(__m512i a);
```

Reduces the packed int32 elements in *a* by bitwise `AND`.

Returns the bitwise `AND` of all elements in *a*.

_mm512_mask_reduce_and_epi32

```
extern int __cdecl _mm512_mask_reduce_and_epi32(__mmask16 k, __m512i a);
```

Reduces the packed int32 elements in *a* by bitwise `AND` using mask *k*.

Returns the bitwise `AND` of all active elements in *a*.

_mm512_reduce_and_epi64

```
extern __int64 __cdecl _mm512_reduce_and_epi64(__m512i a);
```

Reduces the packed int64 elements in *a* by bitwise `AND`.

Returns the bitwise `AND` of all elements in *a*.

_mm512_mask_reduce_and_epi64

```
extern __int64 __cdecl _mm512_mask_reduce_and_epi64(__mmask8 k, __m512i a);
```

Reduces the packed int64 elements in *a* by bitwise `AND` using mask *k*.

Only those elements in the source registers with the corresponding bit set in vector mask *k* are used for computing. Elements in *a* with corresponding bit clear in *k* are copied as is to the resulting vector.

Returns the bitwise `AND` of all active elements in *a*.

_mm512_reduce_add_epi32

```
extern int __cdecl _mm512_reduce_add_epi32(__m512i a);
```

Reduces the packed int32 elements in *a* by addition.

Returns the sum of all elements in *a*.

_mm512_mask_reduce_add_epi32

```
extern int __cdecl _mm512_mask_reduce_add_epi32(__mmask16 k, __m512i a);
```

Reduces the packed int32 elements in *a* by addition using mask *k*.

Returns the sum of all active elements in *a*.

_mm512_reduce_add_epi64

```
extern __int64 __cdecl _mm512_reduce_add_epi64(__m512i a);
```

Reduces the packed int64 elements in *a* by addition.

Returns the sum of all elements in *a*.

_mm512_mask_reduce_add_epi64

```
extern __int64 __cdecl _mm512_mask_reduce_add_epi64(__mmask8 k, __m512i a);
```

Reduce the packed int64 elements in *a* by addition, using mask *k*.

Only those elements in the source registers with the corresponding bit set in vector mask *k* are used for computing. Elements in *a* with corresponding bit clear in *k* are copied as is to the resulting vector.

Returns the sum of all active elements in *a*.

_mm512_reduce_max_epi32

```
extern int __cdecl _mm512_reduce_max_epi32(__m512i a);
```

Reduce the packed int32 elements in *a* by maximum.

Returns the maximum of all elements in *a*.

_mm512_mask_reduce_max_epi32

```
extern int __cdecl _mm512_mask_reduce_max_epi32(__mmask16 k, __m512i a);
```

Reduce the packed int32 elements in *a* by maximum using mask *k*.

Returns the maximum of all active elements in *a*.

_mm512_reduce_max_epi64

```
extern __int64 __cdecl _mm512_reduce_max_epi64(__m512i a);
```

Reduce the packed int64 elements in *a* by maximum.

Returns the maximum of all elements in *a*.

_mm512_mask_reduce_max_epi64

```
extern __int64 __cdecl _mm512_mask_reduce_max_epi64(__mmask8 k, __m512i a);
```

Reduce the packed int64 elements in *a* by maximum using mask *k*.

Only those elements in the source registers with the corresponding bit set in vector mask *k* are used for computing. Elements in *a* with corresponding bit clear in *k* are copied as is to the resulting vector.

Returns the maximum of all active elements in *a*.

_mm512_reduce_max_epu32

```
extern unsigned int __cdecl _mm512_reduce_max_epu32(__m512i a);
```

Reduce the packed unsigned int32 elements in *a* by maximum.

Returns the maximum of all elements in *a*.

_mm512_mask_reduce_max_epu32

```
extern unsigned int __cdecl _mm512_mask_reduce_max_epu32(__mmask16 k, __m512i a);
```

Reduce the packed unsigned int32 elements in *a* by maximum using mask *k*.

Returns the maximum of all active elements in *a*.

_mm512_reduce_max_epu64

```
extern unsigned __int64 __cdecl _mm512_reduce_max_epu64(__m512i a);
```

Reduce the packed unsigned int64 elements in *a* by maximum.

Returns the maximum of all elements in *a*.

_mm512_mask_reduce_max_epu64

```
extern unsigned __int64 __cdecl _mm512_mask_reduce_max_epu64(__mmask8 k, __m512i a);
```

Reduce the packed unsigned int64 elements in *a* by maximum using mask *k*.

Only those elements in the source registers with the corresponding bit set in vector mask *k* are used for computing. Elements in *a* with corresponding bit clear in *k* are copied as is to the resulting vector.

Returns the maximum of all active elements in *a*.

_mm512_reduce_min_epi32

```
extern int __cdecl _mm512_reduce_min_epi32(__m512i a);
```

Reduce the packed int32 elements in *a* by minimum.

Returns the minimum of all elements in *a*.

_mm512_mask_reduce_min_epi32

```
extern int __cdecl _mm512_mask_reduce_min_epi32(__mmask16 k, __m512i a);
```

Reduce the packed int32 elements in *a* by maximum using mask *k*.

Returns the minimum of all active elements in *a*.

_mm512_reduce_min_epi64

```
extern __int64 __cdecl _mm512_reduce_min_epi64(__m512i a);
```

Reduce the packed int64 elements in *a* by minimum.

Returns the minimum of all elements in *a*.

_mm512_mask_reduce_min_epi64

```
extern __int64 __cdecl _mm512_mask_reduce_min_epi64(__mmask8 k, __m512i a);
```

Reduce the packed int64 elements in *a* by maximum, using mask *k*.

Only those elements in the source registers with the corresponding bit set in vector mask *k* are used for computing. Elements in *a* with corresponding bit clear in *k* are copied as is to the resulting vector.

Returns the minimum of all active elements in *a*.

_mm512_reduce_min_epu32

```
extern unsigned int __cdecl _mm512_reduce_min_epu32(__m512i a);
```

Reduce the packed unsigned int32 elements in *a* by minimum.

Returns the minimum of all elements in *a*.

_mm512_mask_reduce_min_epu32

```
extern unsigned int __cdecl _mm512_mask_reduce_min_epu32(__mmask16 k, __m512i a);
```

Reduce the packed unsigned int32 elements in *a* by maximum using mask *k*.

Returns the minimum of all active elements in *a*.

_mm512_reduce_min_epu64

```
extern unsigned __int64 __cdecl _mm512_reduce_min_epu64(__m512i a);
```

Reduce the packed unsigned int64 elements in *a* by minimum.

Returns the minimum of all elements in *a*.

_mm512_mask_reduce_min_epu64

```
extern unsigned __int64 __cdecl _mm512_mask_reduce_min_epu64(__mmask8 k, __m512i a);
```

Reduce the packed unsigned int64 elements in *a* by minimum using mask *k*.

Only those elements in the source registers with the corresponding bit set in vector mask *k* are used for computing. Elements in *a* with corresponding bit clear in *k* are copied as is to the resulting vector.

Returns the minimum of all active elements in *a*.

_mm512_reduce_mul_epi32

```
extern int __cdecl _mm512_reduce_mul_epi32(__m512i a);
```

Reduce the packed int32 elements in *a* by multiplication.

Returns the product of all elements in *a*.

_mm512_mask_reduce_mul_epi32

```
extern int __cdecl _mm512_mask_reduce_mul_epi32(__mmask16 k, __m512i a);
```

Reduce the packed int32 elements in *a* by multiplication using mask *k*.

Returns the product of all active elements in *a*.

_mm512_reduce_mul_epi64

```
extern __int64 __cdecl _mm512_reduce_mul_epi64(__m512i a);
```

Reduce the packed int64 elements in *a* by multiplication.

Returns the product of all elements in *a*.

_mm512_mask_reduce_mul_epi64

```
extern __int64 __cdecl _mm512_mask_reduce_mul_epi64(__mmask8 k, __m512i a);
```

Reduce the packed int64 elements in *a* by multiplication using mask *k*.

Only those elements in the source registers with the corresponding bit set in vector mask *k* are used for computing. Elements in *a* with corresponding bit clear in *k* are copied as is to the resulting vector.

Returns the product of all active elements in *a*.

_mm512_reduce_or_epi32

```
extern int __cdecl _mm512_reduce_or_epi32(__m512i a);
```

Reduce the packed int32 elements in *a* by bitwise `OR`.

Returns the bitwise `OR` of all elements in *a*.

_mm512_mask_reduce_or_epi32

```
extern int __cdecl _mm512_mask_reduce_or_epi32(__mmask16 k, __m512i a);
```

Reduce the packed int32 elements in *a* by bitwise `OR` using mask *k*.

Returns the bitwise `OR` of all active elements in *a*.

_mm512_reduce_or_epi64

```
extern __int64 __cdecl _mm512_reduce_or_epi64(__m512i a);
```

Reduce the packed int64 elements in *a* by bitwise `OR`.

Returns the bitwise `OR` of all elements in *a*.

_mm512_mask_reduce_or_epi64

```
extern __int64 __cdecl _mm512_mask_reduce_or_epi64(__mmask8 k, __m512i a);
```

Reduce the packed int64 elements in *a* by bitwise `OR` using mask *k*.

Only those elements in the source registers with the corresponding bit set in vector mask *k* are used for computing. Elements in *a* with corresponding bit clear in *k* are copied as is to the resulting vector.

Returns the bitwise `OR` of all active elements in *a*.

Intrinsics for Set Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Setting Vectors of Undefined Value

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_undefined`	Returns vector of type `__m512i` with undefined elements.	**None.**
`_mm512_undefined_epi32`	Returns vector of type `__m512i` with undefined elements.	**None.**

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_undefined_pd`	Returns vector of type `__m512d` with undefined elements.	**None.**
`_mm512_undefined_ps`	Returns vector of type `__m512` with undefined elements.	**None.**
`_mm512_set1_pd`	Broadcast float64 element to all destination elements.	**None.**
`_mm512_set1_ps`	Broadcast float32 element to all destination elements.	**None.**
`_mm512_set4_pd`	Broadcast float64 element to destination elements with repeated four element sequence.	**None.**
`_mm512_set4_ps`	Broadcast float32 element to destination elements with repeated four element sequence.	**None.**
`_mm512_set_pd`	Broadcast packed float64 elements with supplied values.	**None.**
`_mm512_set_ps`	Broadcast packed float32 elements with supplied values.	**None.**
`_mm512_setr4_pd`	Broadcast packed float64 elements with the repeated four element sequence in reverse order.	**None.**
`_mm512_setr4_ps`	Broadcast packed float32 elements with the repeated four element sequence in reverse order.	**None.**
`_mm512_setr_pd`	Broadcast packed float64 elements with supplied values in reverse order.	**None.**
`_mm512_setr_ps`	Broadcast packed float32 elements with supplied values in reverse order.	**None.**
`_mm512_setzero_pd`	Returns vector of type `__m512d` with all elements set to zero.	`VXORPD`
`_mm512_setzero_ps`	Returns vector of type `__m512` with all elements set to zero.	`VXORPS`
`_mm512_undefined_pd`	Returns vector of type `__m512d` with undefined elements.	**None.**
`_mm512_undefined_ps`	Returns vector of type `__m512` with undefined elements.	**None.**

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_set1_epi8	Broadcast 8-bit integer *a* to all destination elements.	VPBROADCASTB
_mm512_set1_epi32, _mm512_mask_set1_epi32, _mm512_maskz_set1_epi32	Broadcast a single int32 element to all destination elements.	VPBROADCASTD
_mm512_set1_epi64, _mm512_mask_set1_epi64, _mm512_maskz_set1_epi64	Broadcast a single int64 element to all destination elements.	VPBROADCASTQ
_mm512_set1_epi16	Broadcast a single int16 element to all destination elements	VPBROADCASTW
_mm512_set4_epi32	Broadcast packed int32 elements with repeated four element sequence.	**None.**
_mm512_set4_epi64	Broadcast packed int64 elements in with repeated four element sequence.	**None.**
_mm512_set_epi32	Broadcast packed int32 elements with supplied values.	**None.**
_mm512_set_epi64	Broadcast packed int64 elements with supplied values.	**None.**
_mm512_setr4_epi32	Broadcast packed int32 elements with repeated four element sequence in reverse order.	**None.**
_mm512_setr4_epi64	Broadcast packed int64 elements with repeated four element sequence in reverse order.	**None.**
_mm512_setr_epi32	Broadcast packed int32 elements with supplied values in reverse order.	**None.**
_mm512_setr_epi64	Broadcast packed int64 elements with supplied values in reverse order.	**None.**
_mm512_setzero_epi32 _mm512_setzero_si512	Returns vector of type __m512i with all elements set to zero.	VPXOR

variable	definition
k	writemask used as a selector
a	first source vector element

variable	definition
e	elements for set operation
a, *b*, *c*, *d*	elements for set operation

_mm512_set1_pd

```
extern __m512d __cdecl _mm512_set1_pd(double a);
```

Broadcasts float64 value *a* to all destination elements.

_mm512_set1_ps

```
extern __m512 __cdecl _mm512_set1_ps(float a);
```

Broadcasts float32 value *a* to all destination elements.

_mm512_set4_pd

```
extern __m512d __cdecl _mm512_set4_pd(double d, double c, double b, double a);
```

Sets packed float64 elements in destination with the repeated four element sequence (dcba dcba).

_mm512_set4_ps

```
extern __m512 __cdecl _mm512_set4_ps(float d, float c, float b, float a);
```

Sets packed float32 elements in destination with the repeated four element sequence. (dcba dcba dcba dcba).

_mm512_set_pd

```
extern __m512 __cdecl _mm512_set_pd(float e7, float e6, float e5, float e4, float e3, float e2,
float e1, float e0);
```

Sets packed float64 elements in destination with supplied values.

_mm512_set_ps

```
extern __m512 __cdecl _mm512_set_ps(float e15, float e14, float e13, float e12, float e11, float
e10, float e9, float e8, float e7, float e6, float e5, float e4, float e3, float e2, float e1,
float e0);
```

Sets packed float32 elements in destination with supplied values.

_mm512_setr4_pd

```
extern __m512d __cdecl _mm512_setr4_pd(double a, double b, double c, double d);
```

Broadcast packed float64 elements in destination with the repeated four element sequence in reverse order.

_mm512_setr4_ps

```
extern __m512 __cdecl _mm512_setr4_ps(float a, float b, float c, float d);
```

Sets packed float32 elements in destination with the repeated four element sequence in reverse order.

_mm512_setr_pd

```
extern __m512d __cdecl _mm512_setr_pd(double e0, double e1, double e2, double e3, double e4,
double e5, double e6, double e7);
```

Sets packed float64 elements in destination with supplied values in reverse order.

_mm512_setr_ps

```
extern __m512 __cdecl _mm512_setr_ps(float e0, float e1, float e2, float e3, float e4, float e5,
float e6, float e7, float e8, float e9, float e10, float e11, float e12, float e13, float e14,
float e15);
```

Sets packed float32 elements in destination with supplied values in reverse order.

_mm512_setzero_pd

```
extern __m512 __cdecl _mm512_setzero_pd(void);
```

Returns vector of type `__m512d` with all elements set to zero.

_mm512_setzero_ps

```
extern __m512 __cdecl _mm512_setzero_ps(void);
```

Returns vector of type `__m512` with all elements set to zero.

_mm512_undefined_pd

```
extern __m512 __cdecl _mm512_undefined_pd(void)
```

Returns vector of type `__m512d` with undefined elements.

_mm512_undefined_ps

```
extern __m512 __cdecl _mm512_undefined_ps(void)
```

Returns vector of type `__m512` with undefined elements.

_mm512_set1_epi16

```
extern __m512i __cdecl _mm512_set1_epi16(short a);
```

Broadcast int16 *a* to all destination elements.

_mm512_set1_epi8

```
extern __m512i __cdecl _mm512_set1_epi8(char a);
```

Broadcasts int8 *a* to all destination elements.

_mm512_set1_epi32

```
extern __m512i __cdecl _mm512_set1_epi32(int a);
```

Broadcasts int32 *a* to all destination elements.

_mm512_mask_set1_epi32

```
extern __m512i __cdecl _mm512_mask_set1_epi32(__m512i src, __mmask16 k, int a);
```

Broadcasts int32 *a* to all destination elements using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_set1_epi32

```
extern __m512i __cdecl _mm512_maskz_set1_epi32(__mmask16 k, int a);
```

Broadcasts int32 *a* to all destination elements using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_set1_epi64

```
extern __m512i __cdecl _mm512_set1_epi64(__int64 a);
```

Broadcasts int64 *a* to all destination elements.

_mm512_mask_set1_epi64

```
extern __m512i __cdecl _mm512_mask_set1_epi64(__m512i src, __mmask8 k, __int64 a);
```

Broadcasts int64 *a* to all destination elements using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_set1_epi64

```
extern __m512i __cdecl _mm512_maskz_set1_epi64(__mmask8 k, __int64 a);
```

Broadcasts int64 *a* to all destination elements using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_set4_epi32

```
extern __m512i __cdecl _mm512_set4_epi32(int d, int c, int b, int a);
```

Sets packed int32 in destination with the repeated four element sequence.

_mm512_set4_epi64

```
extern __m512i __cdecl _mm512_set4_epi64(__int64 d, __int64 c, __int64 b, __int64 a);
```

Sets packed int64 in destination with the repeated four element sequence.

_mm512_set_epi32

```
extern __m512i __cdecl _mm512_set_epi32(int e15, int e14, int e13, int e12, int e11, int e10,
int e9, int e8, int e7, int e6, int e5, int e4, int e3, int e2, int e1, int e0);
```

Sets packed int32 in destination with supplied values.

_mm512_set_epi64

```
extern __m512i __cdecl _mm512_set_epi64(__int64 e7, __int64 e6, __int64 e5, __int64 e4, __int64
e3, __int64 e2, __int64 e1, __int64 e0);
```

Sets packed int64 in destination with supplied values.

_mm512_setr4_epi32

```
extern __m512i __cdecl _mm512_setr4_epi32(int a, int b, int c, int d);
```

Sets packed int32 in destination with the repeated four element sequence in reverse order.

_mm512_setr4_epi64

```
extern __m512i __cdecl _mm512_setr4_epi64(__int64 a, __int64 b, __int64 c, __int64 d);
```

Sets packed int64 in destination with the repeated four element sequence in reverse order.

_mm512_setr_epi32

```
extern __m512i __cdecl _mm512_setr4_epi32(int a, int b, int c, int d);
```

Sets packed int32 in destination with supplied values in reverse order.

_mm512_setr_epi64

```
extern __m512i __cdecl _mm512_setr_epi64(__int64 e0, __int64 e1, __int64 e2, __int64 e3, __int64
e4, __int64 e5, __int64 e6, __int64 e7);
```

Sets packed int64 in destination with supplied values in reverse order.

_mm512_setzero_epi32

```
extern __m512 __cdecl _mm512_setzero(void);
```

Returns vector of type `__m512i` with all elements set to zero.

_mm512_setzero_si512

```
extern __m512 __cdecl _mm512_setzero(void);
```

Returns vector of type `__m512i` with all elements set to zero.

_mm512_undefined_epi32

```
extern __m512 __cdecl _mm512_undefined_epi32(void);
```

Returns vector of type `__m512i` with undefined elements.

_mm512_setzero

```
extern __m512 __cdecl _mm512_setzero(void);
```

Returns vector of type `__m512` with all elements set to zero.

_mm512_undefined

```
extern __m512 __cdecl _mm512_undefined(void);
```

Returns vector of type `__m512` with undefined elements.

Intrinsics for Shuffle Operations

Intrinsics for FP Shuffle Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_shuffle_pd`, `_mm512_mask_shuffle_pd`, `_mm512_maskz_shuffle_pd`	Shuffle float64 values.	`VSHUFPD`
`_mm512_shuffle_ps`, `_mm512_mask_shuffle_ps`, `_mm512_maskz_shuffle_ps`	Shuffle float32 values.	`VSHUFPS`
`_mm512_shuffle_f64x2`, `_mm512_mask_shuffle_f64x2`, `_mm512_maskz_shuffle_f64x2`	Shuffle float64 values and store using mask.	`VSHUFF64X2`
`_mm512_shuffle_f32x4`, `_mm512_mask_shuffle_f32x4`, `_mm512_maskz_shuffle_f32x4`	Shuffle float32 values and store using mask.	`VSHUFF32X4`

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result
imm	vector element selector

_mm512_shuffle_f32x4

```
extern __m512 __cdecl _mm512_shuffle_f32x4(__m512 a, __m512 b, const int imm);
```

Shuffles four float32 elements from *a* and *b*, selected by *imm*, and stores the result.

_mm512_mask_shuffle_f32x4

```
extern __m512 __cdecl _mm512_mask_shuffle_f32x4(__m512 src, __mmask16 k, __m512 a, __m512 b,
const int imm);
```

Shuffles four float32 elements from *a* and *b*, selected by *imm*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_shuffle_f32x4

```
extern __m512 __cdecl _mm512_maskz_shuffle_f32x4(__mmask16 k, __m512 a, __m512 b, const int imm);
```

Shuffles four float32 elements from *a* and *b*, selected by *imm*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_shuffle_f64x2

```
extern __m512d __cdecl _mm512_shuffle_f64x2(__m512d a, __m512d b, const int imm);
```

Shuffles 128-bits (composed of two float64 elements from *a* and *b*, selected by *imm*, and stores the result.

_mm512_mask_shuffle_f64x2

```
extern __m512d __cdecl _mm512_mask_shuffle_f64x2(__m512d src, __mmask8 k, __m512d a, __m512d b,
const int imm);
```

Shuffles 128-bits (composed of two float64 elements from *a* and *b*, selected by *imm*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_shuffle_f64x2

```
extern __m512d __cdecl _mm512_maskz_shuffle_f64x2(__mmask8 k, __m512d a, __m512d b, const int
imm);
```

Shuffles 128-bits (composed of two float64 elements from *a* and *b*, selected by *imm*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_shuffle_pd

```
extern __m512d __cdecl _mm512_shuffle_pd(__m512d a, __m512d b, const int imm);
```

Shuffles float64 elements from vectors *a* and *b* within 128-bit lanes using the control in *imm*, and stores the result.

_mm512_mask_shuffle_pd

```
extern __m512d __cdecl _mm512_mask_shuffle_pd(__m512d src, __mmask8 k, __m512d a, __m512d b,
const int imm);
```

Shuffle float64 elements from vectors *a* and *b* within 128-bit lanes using the control in *imm*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_shuffle_pd

```
extern __m512d __cdecl _mm512_maskz_shuffle_pd(__mmask8 k, __m512d a, __m512d b, const int imm);
```

Shuffle float64 elements from vectors *a* and *b* within 128-bit lanes using the control in *imm*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_shuffle_ps

```
extern __m512 __cdecl _mm512_shuffle_ps(__m512 a, __m512 b, const int imm);
```

Shuffles float32 elements from vectors *a* and *b* within 128-bit lanes using the control in *imm*, and stores the result.

_mm512_mask_shuffle_ps

```
extern __m512 __cdecl _mm512_mask_shuffle_ps(__m512 src, __mmask16 k, __m512 a, __m512 b, const
int imm);
```

Shuffle float32 elements from vectors *a* and *b* within 128-bit lanes using the control in *imm*, and stores the result using writemask *k*.

Elements are copied from *src* when the corresponding mask bit is not set.

_mm512_maskz_shuffle_ps

```
extern __m512 __cdecl _mm512_maskz_shuffle_ps(__mmask16 k, __m512 a, __m512 b, const int imm);
```

Shuffle float32 elements from vectors *a* and *b* within 128-bit lanes using the control in *imm*, and stores the result using zeromask *k*.

Elements are zeroed out when the corresponding mask bit is not set.

Intrinsics for Integer Shuffle Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_shuffle_epi32, _mm512_mask_shuffle_epi32, _mm512_maskz_shuffle_epi32	Shuffle int32 vectors within 128-bit lanes using control value.	VPSHUFD
_mm512_shuffle_i32x4, _mm512_mask_shuffle_i32x4, _mm512_maskz_shuffle_i32x4	Shuffle four int32 values by specified value.	VSHUFI32X4
_mm512_shuffle_i64x2, _mm512_mask_shuffle_i64x2, _mm512_maskz_shuffle_i64x2	Shuffle two int64 values by specified value.	VSHUFI64X2

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result
imm	control value for shuffle operation

_mm512_shuffle_epi32

```
extern __m512i _cdecl __m512_shuffle_epi32(__m512i a, _MM_PERM_ENUM imm);
```

Shuffles int32 in *a* within 128-bit lanes using the control in *imm*, and stores the result.

_mm512_mask_shuffle_epi32

```
extern __m512i _cdecl __m512_mask_shuffle_epi32(__m512i src, __mmask16 k, __m512i a,
_MM_PERM_ENUM imm);
```

Shuffles int32 in *a* within 128-bit lanes using the control in *imm*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_shuffle_epi32

```
extern__m512i _cdecl __m512_maskz_shuffle_epi32(__mmask16 k, __m512i a, _MM_PERM_ENUM imm);
```

Shuffles int32 in *a* within 128-bit lanes using the control in *imm*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_shuffle_i32x4

```
extern __m512i _cdecl __m512_shuffle_i32x4(__m512i a, __m512i b, _MM_PERM_ENUM imm);
```

Shuffles 128-bits (composed of four int32) selected by *imm* from *a* and *b*, and stores the result.

_mm512_mask_shuffle_i32x4

```
extern __m512i _cdecl __m512_mask_shuffle_i32x4(__m512i src, __mmask16 k, __m512i a, __m512i b,
_MM_PERM_ENUM imm);
```

Shuffles 128-bits (composed of four int32) selected by *imm* from *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_shuffle_i32x4

```
extern __m512i _cdecl __m512_maskz_shuffle_i32x4(__mmask16 k, __m512i a, __m512i b,
_MM_PERM_ENUM imm);
```

Shuffles 128-bits (composed of four int32) selected by *imm* from *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_shuffle_i64x2

```
extern __m512i _cdecl __m512_shuffle_i64x2(__m512i a, __m512i b, _MM_PERM_ENUM imm);
```

Shuffles 128-bits (composed of two int64) selected by *imm* from *a* and *b*, and stores the result.

_mm512_mask_shuffle_i64x2

```
extern __m512i _cdecl __m512_mask_shuffle_i64x2(__m512i src, __mmask8 k, __m512i b, __m512i b,
_MM_PERM_ENUM imm);
```

Shuffles 128-bits (composed of two int64) selected by *imm* from *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_shuffle_i64x2

```
extern __m512i _cdecl __m512_maskz_shuffle_i64x2(__mmask8 k, __m512i a, __m512i b, _MM_PERM_ENUM
imm);
```

Shuffles 128-bits (composed of two int64) selected by *imm* from *a* and *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Intrinsics for Test Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_conflict_epi32`, `_mm512_mask_conflict_epi32`, `_mm512_maskz_conflict_epi32`	Test int32 elements for equality.	`VPCONFLICTD`
`_mm512_conflict_epi64`, `_mm512_mask_conflict_epi64`, `_mm512_maskz_conflict_epi64`	Test int64 elements for equality.	`VPCONFLICTQ`
`_mm512_test_epi32_mask`, `_mm512_mask_test_epi32_mask`	Performs a bitwise logical `AND` operation and stores the logical comparison result.	`VPTESTMD`
`_mm512_testn_epi32_mask`, `_mm512_mask_testn_epi32_mask`	Performs a bitwise logical `AND NOT` operation and stores the logical comparison result.	`VPTESTNMD`
`_mm512_test_epi64_mask`, `_mm512_mask_test_epi64_mask`	Performs a bitwise logical `AND` operation and stores the logical comparison result.	`VPTESTMQ`
`_mm512_testn_epi64_mask`, `_mm512_mask_testn_epi64_mask`	Performs a bitwise logical `AND NOT` operation and stores the logical comparison result.	`VPTESTNMQ`

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result

_mm512_conflict_epi32

```
extern __m512i __cdecl _mm512_conflict_epi32(__m512i a);
```

Tests each 32-bit element of *a* for equality with all other elements in *a* closer to the least significant bit.

Each element's comparison forms a zero extended bit vector in the destination.

_mm512_mask_conflict_epi32

```
extern __m512i __cdecl _mm512_mask_conflict_epi32(__m512i src, __mmask16 k, __m512i a);
```

Tests each 32-bit element of *a* for equality with all other elements in *a* closer to the least significant bit using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

Each element's comparison forms a zero extended bit vector in the destination.

_mm512_maskz_conflict_epi32

```
extern __m512i __cdecl _mm512_maskz_conflict_epi32(__mmask16 k, __m512i a);
```

Tests each 32-bit element of *a* for equality with other elements in *a* closer to the least significant bit using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Each element's comparison forms a zero extended bit vector in the destination.

_mm512_conflict_epi64

```
extern __m512i __cdecl _mm512_conflict_epi64(__m512i a);
```

Tests each 64-bit element of *a* for equality with other elements in *a* closer to the least significant bit.

Each element's comparison forms a zero extended bit vector in the destination.

_mm512_mask_conflict_epi64

```
extern __m512i __cdecl _mm512_mask_conflict_epi64(__m512i src, __mmask8 k, __m512i a);
```

Tests each 64-bit element of *a* for equality with other elements in *a* closer to the least significant bit using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

Each element's comparison forms a zero extended bit vector in the destination.

_mm512_maskz_conflict_epi64

```
extern __m512i __cdecl _mm512_maskz_conflict_epi64(__mmask8 k, __m512i a);
```

Tests each 64-bit element of *a* for equality with other elements in *a* closer to the least significant bit using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

Each element's comparison forms a zero extended bit vector the destination.

_mm512_test_epi32_mask

```
extern __mmask16 __cdecl _mm512_test_epi32_mask(__m512i a, __m512i b);
```

Computes the bitwise `AND` of packed 32-bit integers in *a* and *b*, producing intermediate 32-bit values, and sets the corresponding bit in result mask *k* if the intermediate value is non-zero.

_mm512_mask_test_epi32_mask

```
extern __mmask16 __cdecl _mm512_mask_test_epi32_mask(__mmask16 k, __m512i a, __m512i b);
```

Computes the bitwise `AND` of packed 32-bit integers in *a* and *b*, producing intermediate 32-bit values, and sets the corresponding bit in result mask *k* (subject to writemask *k*) if the intermediate value is non-zero.

_mm512_test_epi64_mask

```
extern __mmask8 __cdecl _mm512_test_epi64_mask(__m512i a, __m512i b);
```

Computes the bitwise `AND` of packed 64-bit integers in *a* and *b*, producing intermediate 64-bit values, and sets the corresponding bit in result mask *k* if the intermediate value is non-zero.

_mm512_mask_test_epi64_mask

```
extern __mmask8 __cdecl _mm512_mask_test_epi64_mask(__mmask8 k, __m512i a, __m512i b);
```

Computes the bitwise AND of packed 64-bit integers in *a* and *b*, producing intermediate 64-bit values, and sets the corresponding bit in result mask *k* (subject to writemask *k*) if the intermediate value is non-zero.

_mm512_testn_epi32_mask

```
extern __mmask16 __cdecl _mm512_testn_epi32_mask(__m512i a, __m512i b);
```

Computes the bitwise AND NOT of packed 32-bit integers in *a* and *b*, producing intermediate 32-bit values, and sets the corresponding bit in result mask *k* if the intermediate value is zero.

_mm512_mask_testn_epi32_mask

```
extern __mmask16 __cdecl _mm512_mask_testn_epi32_mask(__mmask16 k, __m512i a, __m512i b);
```

Computes the bitwise AND NOT of packed 32-bit integers in *a* and *b*, producing intermediate 32-bit values, and sets the corresponding bit in result mask *k* (subject to writemask *k*) if the intermediate value is zero.

_mm512_testn_epi64_mask

```
extern __mmask8 __cdecl _mm512_testn_epi64_mask(__m512i a, __m512i b);
```

Computes the bitwise AND NOT of packed 64-bit integers in *a* and *b*, producing intermediate 64-bit values, and sets the corresponding bit in result mask *k* if the intermediate value is zero.

_mm512_mask_testn_epi64_mask

```
extern __mmask8 __cdecl _mm512_mask_testn_epi64_mask(__mmask8 k, __m512i a, __m512i b);
```

Computes the bitwise AND NOT of packed 64-bit integers in *a* and *b*, producing intermediate 64-bit values, and sets the corresponding bit in result mask *k* (subject to writemask *k*) if the intermediate value is zero.

Intrinsics for Typecast Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the zmmintrin.h header file.
To use these intrinsics, include the immintrin.h file as follows:

```
#include <immintrin.h>
```

NOTE
These intrinsics are used for compilation and do not generate any instructions.

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_castpd512_pd128	Casts from larger type to smaller type.	**None.**

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_castps512_ps128	Casts from larger type to smaller type.	**None.**
_mm512_castsi512_si128	Casts from larger type to smaller type.	**None.**
_mm512_castpd512_pd256	Casts from larger type to smaller type.	**None.**
_mm512_castps512_ps256	Casts from larger type to smaller type.	**None.**
_mm512_castsi512_si256	Casts from larger type to smaller type.	**None.**

_mm512_castsi512_ps	Casts from smaller type to larger type.	**None.**

variable	definition
a	vector element for casting operation

_mm512_castpd_ps

```
extern __m512 __cdecl _mm512_castpd_ps(__m512d a);
```

Casts vector *a* of type `__m512d` to type `__m512`, with no change in value.

_mm512_castpd_si512

```
extern __m512i __cdecl _mm512_castpd_si512(__m512d a);
```

Casts vector *a* of type `__m512d` to type `__m512i`, with no change in value.

_mm512_castps_pd

```
extern __m512d __cdecl _mm512_castps_pd(__m512 a);
```

Casts vector *a* of type `__m512` to type `__m512d`, with no change in value.

_mm512_castps_si512

```
extern __m512i __cdecl _mm512_castps_si512(__m512 a);
```

Casts vector *a* of type `__m512` to type `__m512i`, with no change in value.

_mm512_castpd128_pd512

```
extern __m512d __cdecl _mm512_castpd128_pd512(__m128d a);
```

Casts vector *a* of type `__m128d` to type `__m512d`.

> **NOTE**
> The upper 384-bits of the result are undefined.

_mm512_castpd256_pd512

```
extern __m512d __cdecl _mm512_castpd256_pd512(__m256d a);
```

Casts vector *a* of type `__m256d` to type `__m512d`.

> **NOTE**
> The upper 256-bits of the result are undefined.

_mm512_castpd512_pd128

```
extern __m128d __cdecl _mm512_castpd512_pd128(__m512d a);
```

Casts vector *a* of type `__m512d` to type `__m128d`.

_mm512_castps512_ps128

```
extern __m128 __cdecl _mm512_castps512_ps128(__m512 a);
```

Casts vector *a* of type `__m512` to type `__m128`.

_mm512_castpd512_pd256

```
extern __m256d __cdecl _mm512_castpd512_pd256(__m512d a);
```

Casts vector *a* of type `__m512d` to type `__m256d`.

_mm512_castps128_ps512

```
extern __m512 __cdecl _mm512_castps128_ps512(__m128 a);
```

Casts vector *a* of type `__m128` to type `__m512`.

NOTE
The upper 384-bits of the result are undefined.

_mm512_castps256_ps512

```
extern __m512 __cdecl _mm512_castps256_ps512(__m256 a);
```

Casts vector *a* of type `__m256` to type `__m512`.

NOTE
The upper 256-bits of the result are undefined.

_mm512_castps512_ps256

```
extern __m256 __cdecl _mm512_castps512_ps256(__m512 a);
```

Casts vector *a* of type `__m512` to type `__m256`.

_mm512_castsi128_si512

```
extern __m512i __cdecl _mm512_castsi128_si512(__m128i a);
```

Casts vector *a* of type `__m128i` to type `__m512i`.

NOTE
The upper 384-bits of the result are undefined.

_mm512_castsi256_si512

```
extern __m512i __cdecl _mm512_castsi256_si512(__m256i a);
```

Casts vector *a* of type `__m256i` to type `__m512i`.

NOTE
The upper 256-bits of the result are undefined.

_mm512_castsi512_pd

```
extern __m512d __cdecl _mm512_castsi512_pd(__m512i a);
```

Casts vector *a* of type `__m512i` to type `__m512d`, with no change in value.

_mm512_castsi512_ps

```
extern __m512 __cdecl _mm512_castsi512_ps(__m512i a);
```

Casts vector *a* of type `__m512i` to type `__m512`, with no change in value.

_mm512_castsi512_si128

```
extern __m128i __cdecl _mm512_castsi512_si128(__m512i a);
```

Casts vector *a* of type `__m512d` to type `__m256d`.

_mm512_castsi512_si256

```
extern __m256i __cdecl _mm512_castsi512_si256(__m512i a);
```

Casts vector *a* of type `__m512i` to type `__m256i`.

Intrinsics for Vector Mask Operations

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_kand`	Bitwise logical `AND` masks.	`KANDW`
`_mm512_kandn`	Bitwise logical `AND NOT` masks.	`KANDNW`
`_mm512_kmov`	Move to and from mask registers.	`KMOVW`
`_mm512_kunpackb`	Unpack mask registers.	`KUNPCKBW`
`_mm512_knot`	Bitwise logical `NOT` masks.	`KNOTW`
`_mm512_kor`	Bitwise logical `OR` masks.	`KORW`
`_mm512_kortestc` `_mm512_kortestz`	Bitwise logical `OR` mask and set flag.	`KORTESTW`
`_mm512_kxnor`	Bitwise logical `XNOR` masks.	`KXNORW`
`_mm512_kxor`	Bitwise logical `XOR` masks.	`KXORW`

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element

_mm512_kand

```
extern __mmask16 __cdecl _mm512_kand(__mmask16 a, __mmask16 b);
```

Computes the bitwise `AND` of 16-bit masks *a* and *b*, and stores the result in *k*.

_mm512_kandn

```
extern __mmask16 __cdecl _mm512_kandn(__mmask16 a, __mmask16 b);
```

Computes the bitwise `AND NOT` of 16-bit masks *a* and *b*, and stores the result in *k*.

_mm512_knot

```
extern __mmask16 __cdecl _mm512_knot(__mmask16 a);
```

Computes the bitwise `NOT` of 16-bit mask *a*, and stores the result in *k*.

_mm512_kor

```
extern __mmask16 __cdecl _mm512_kor(__mmask16 a, __mmask16 b);
```

Computes the bitwise `OR` of 16-bit masks *a* and *b*, and stores the result in *k*.

_mm512_kxnor

```
extern __mmask16 __cdecl _mm512_kxnor(__mmask16 a, __mmask16 b);
```

Computes the bitwise `XNOR` of 16-bit masks *a* and *b*, and stores the result in *k*.

_mm512_kxor

```
extern __mmask16 __cdecl _mm512_kxor(__mmask16 a, __mmask16 b);
```

Computes the bitwise `XOR` of 16-bit masks *a* and *b*, and stores the result in *k*.

_mm512_kmov

```
extern __mmask16 __cdecl _mm512_kmov(__mmask16 a);
```

Copies 16-bit mask *a* to *k*.

_mm512_kunpackb

```
extern __mmask16 __cdecl _mm512_kunpackb(__mmask16 a, __mmask16 b);
```

Unpacks and interleaves eight bits from 16-bit masks *a* and *b*, and stores the 16-bit result in mask register.

Intrinsics for Later Generation Intel® Core™ Processor Instruction Extensions

This section discusses intrinsics for 3rd and 4th generation Intel® Core™ Processor instruction extensions, intrinsics for converting half floats, intrinsics that generate random numbers, intrinsics for multi-precision arithmetic, and intrinsics that allow reads and writes to the FS base and GS base registers.

Intrinsics for 3rd Generation Intel® Core™ Processor Instruction Extensions

The 3rd Generation Intel® Core™ Processor Instruction Extension intrinsics are assembly-coded functions that call on 3rd Generation Intel® Core™ Processor Instructions that include new vector SIMD and scalar instructions targeted for Intel® 64 architecture processors in process technology smaller than 32nm.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Functional Overview

The 3rd Generation Intel® Core™ Processor Instruction Extensions include:

- Four intrinsics that map to two hardware instructions `VCVTPS2PH` and `VCVTPH2PS` performing 16-bit floating-point data type conversion to and from single-precision floating-point data type. The intrinsics for conversion to packed 16-bit floating-point values from packed single-precision floating-point values also provide rounding control using an immediate byte.
- Three intrinsics that map to the hardware instruction `RDRAND`. The intrinsics generate random numbers of 16/32/64 bit wide random integers.
- Eight intrinsics that map to the hardware instructions `RDFSBASE`, `RDGSBASE`, `WRFSBASE`, and `WRGSBASE`. The intrinsics allow software that works in the 64-bit environment to read and write the FS base and GS base registers at all privileged levels.

Intrinsics for 4th Generation Intel® Core™ Processor Instruction Extensions

The 4th Generation Intel® Core™ Processor Instruction Extensions intrinsics are assembly-coded functions that call on 4th Generation Intel® Core™ Processor Instructions that include scalar instructions targeted for Intel® 64 architecture processors in process technology smaller than 32nm.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Functional Overview

The 4th Generation Intel® Core™ Processor Instruction Extensions include:

- Four intrinsics that map to two hardware instructions `ADOX` and `ADCX` performing 32-bit or 64-bit arithmetic operations with flags.
- One intrinsic that maps to the hardware instruction, `PREFETCHW`. This intrinsic allows data to be to prefetched into the cache in anticipation of a write. This intrinsic can be found in the Cacheability Support Intrinsics section.
- Three intrinsics that map to the hardware instruction `RDSEED`. The intrinsics generate random numbers of 16/32/64 bit wide random integers.

Intrinsics for Converting Half Floats that Map to 3rd Generation Intel® Core™ Processor Instructions

There are four intrinsics for converting the half-float values.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

These intrinsics convert packed half-precision values starting from the first CPUs with the Intel® AVX instructions support that do not really have any special instructions performing FP16 conversions. Therefore, the intrinsics are lowered to runtime library function calls and map to 3rd Generation Intel® Core™ Processor instructions only when such a processor is specified as target CPU using the `-Qx<CPU>/-x<CPU>` option, where <CPU> is the name of a CPU with support of 3rd Generation Intel® Core™ Processor Instruction Extensions.

See Also

Intrinsics for Converting Half Floats

_mm_cvtph_ps()

Converts four half-precision (16-bit) floating point values to single-precision floating point values. The corresponding 3rd Generation Intel® Core™ Processor extension instruction is `VCVTPH2PS`.

Syntax

```
extern __m128 _mm_cvtph_ps(__m128i x, int imm);
```

Arguments

X	a vector containing four 16-bit FP values
Imm	a conversion control constant

Description

This intrinsic converts four half-precision (16-bit) floating point values to single-precision floating point values.

Returns

A vector containing four single-precision floating point elements.

_mm256_cvtph_ps()

Converts eight half-precision (16-bit) floating point values to single-precision floating point values. The corresponding 3rd Generation Intel® Core™ Processor extension instruction is `VCVTPH2PS`.

Syntax

```
extern __m256 _mm256_cvtph_ps(__m128i x);
```

Arguments

x	a vector containing eight 16-bit FP values

Description

This intrinsic converts eight half-precision (16-bit) floating point values to single-precision floating point values.

Returns

A vector containing eight single-precision floating point elements.

_mm_cvtps_ph()

Converts four single-precision floating point values to half-precision (16-bit) floating point values. The corresponding 3rd Generation Intel® Core™ Processor extension instruction is `VCVTPS2PH`.

Syntax

```
extern __m128i _mm_cvtps_ph(__m128 x, int imm);
```

Arguments

X	a vector containing four single-precision FP values
Imm	a conversion control constant

Description

This intrinsic converts four single-precision floating point values to half-precision (16-bit) floating point values.

Returns

A vector containing eight half-precision (16-bit) floating point elements.

_mm256_cvtps_ph()

Converts eight single-precision floating point values to half-precision (16-bit) floating point values. The corresponding 3rd Generation Intel® Core™ Processor extension instruction is `VCVTPS2PH`.

Syntax

```
extern __m128i _mm_cvtps_ph(__m256 x, int imm);
```

Arguments

X	a vector containing eight single-precision FP values
Imm	a conversion control constant

Description

This intrinsic converts eight single-precision floating point values to half-precision (16-bit) floating point values.

Intrinsics that Generate Random Numbers of 16/32/64 Bit Wide Random Integers

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

RDRAND

There are three intrinsics returning a hardware-generated random value.

These intrinsics are mapped to a single `RDRAND` instruction. The exception is the intrinsic `_rdrand64_step()`, which is mapped to two 32-bit `RDRAND` instructions and several shift and conditional jump/move instructions on 32-bit platforms.

RDSEED

There are three intrinsics returning a hardware-generated random value.

These intrinsics are mapped to a code-sequence based on the `RDSEED` instruction. The result code depends on the context in which the intrinsics were used and on the target OS.

_rdrand16_step(), _rdrand32_step(), _rdrand64_step()

Generate random numbers of 16/32/64 bit wide random integers. These intrinsics are mapped to the hardware instruction `RDRAND`.

Syntax

```
extern int _rdrand16_step(unsigned short *random_val);

extern int _rdrand32_step(unsigned int *random_val);

extern int _rdrand64_step(unsigned __int64 *random_val);
```

Description

These intrinsics generate random numbers of 16/32/64 bit wide random integers. The generated random value is written to the given memory location and the success status is returned: '1' if the hardware returned a valid random value, and '0' otherwise.

Returns

1 : if the hardware returns a 16/32/64 random value.

0 : if the hardware does not return any random value.

_rdseed16_step/ _rdseed32_step/ _rdseed64_step

Generates random numbers of 16/32/64 bit wide random integers. The corresponding 4th Generation Intel® Core™ instruction is `RDSEED`.

Syntax

```
extern int _rdseed16_step(unsigned short *random_val);

extern int _rdseed32_step(unsigned int *random_val);

extern int _rdseed64_step(unsigned __int64 *random_val);
```

Parameters

**random_val*	Random value written to the given memory location

Description

These intrinsics generate random numbers of 16/32/64 bit wide random integers. These intrinsics are mapped to a code-sequence based on the `RDSEED` instruction. The result code depends on the context in which the intrinsics were used and on the target operating system.

NOTE
The `_rdrand64_step()` intrinsic can be used only on systems with the 64-bit registers support.

The generated random value is written to the given memory location and the success status is returned: '1' if the hardware returned a valid random value, and '0' otherwise.

NOTE The difference between `RDSEED` and `RDRAND` intrinsics is that `RDSEED` intrinsics meet the NIST SP 800-90B and NIST SP 800-90C standards, while the `RDRAND` meets the NIST SP 800-90A standard.

Returns

The generated random value is written to the given memory location and the success status is returned. Returns '1' if the hardware returns a random 16/32/64 bit value (success). Returns '0' otherwise (failure).

Intrinsics for Multi-Precision Arithmetic

_addcarry_u32(), _addcarry_u64()

Computes sum of two 32/64 bit wide unsigned integer values and a carry-in and returns the value of carry-out produced by the sum. The corresponding 4th Generation Intel® Core™ Processor extension instructions are `ADCX` and `ADOX`.

Syntax

```
extern unsigned char _addcarry_u32(unsigned char c_in, unsigned int src1, unsigned int
src2, unsigned int *sum_out);
```

```
extern unsigned char _addcarry_u64(unsigned char c_in, unsigned __int64 src1, unsigned
__int64 src2, unsigned __int64 *sum_out);
```

Parameters

c_in	Value used for determining carry-in value
src1	32/64 bit source integer
src2	32/64 bit source integer
**sum_out*	Pointer to memory location where result is stored

Description

The intrinsic computes sum of two 32/64 bit wide integer values, *src1* and *src2*, and a carry-in value. The carry-in value is considered '1' for any non-zero *c_in* input value or '0' otherwise. The sum is stored to a memory location referenced by *sum_out* argument:

```
*sum_out = src1 + src2 + (c_in !=0 ? 1 : 0)
```

NOTE
This intrinsic does not perform validity checking of the memory address pointed to by *sum_out*, thus it cannot be used to find out if the sum produces carry-out without storing result of the sum.

Returns

Returns the value of the intrinsic is a carry-out value generated by sum. The sum result is stored into memory location pointed by *sum_out* argument.

_addcarryx_u32(), _addcarryx_u64()

Computes sum of two 32/64 bit wide unsigned integer values and a carry-in and returns the value of carry-out produced by the sum. The corresponding 4th Generation Intel® Core™ Processor extension instructions are `ADCX` and `ADOX`.

Syntax

```
extern unsigned char _addcarryx_u32(unsigned char c_in, unsigned int src1, unsigned int
src2, unsigned int *sum_out);
```

```
extern unsigned char _addcarryx_u64(unsigned char c_in, unsigned __int64 src1, unsigned
__int64 src2, unsigned __int64 *sum_out);
```

Parameters

c_in	Value used for determining carry-in value
src1	32/64 bit source integer
src2	32/64 bit source integer
**sum_out*	Pointer to memory location where result is stored

Description

Computes the sum of two 32/64 bit wide integer values (*src1*, *src2*) and a carry-in value. The carry-in value is considered '1' for any non-zero *c_in* input value, or '0' otherwise. The sum is stored to a memory location referenced by *sum_out* argument:

```
*sum_out = src1 + src2 + (c_in !=0 ? 1 : 0)
```

NOTE
This intrinsic does not perform validity checking of the memory address pointed to by *sum_out*, thus it cannot be used to find out if the sum produces carry-out without storing result of the sum.

The intrinsic is translated to either `ADCX`/`ADOX` instruction, chosen by the compiler. By design, these instructions allow running of two interleaved add-with-carry instruction sequences in parallel via using `ADCX` and `ADOX` instructions for these sequences respectively.

Returns

Returns carry-out value generated by the sum. The sum result is stored into memory location pointed by *sum_out* argument.

_subborrow_u32(), _subborrow_u64()

Computes sum of 32/64 bit unsigned integer value with borrow-in value and then subtracts the result from a 32/64 bit unsigned integer value. The corresponding 4th Generation Intel® Core™ Processor extension instruction is `V`.

Syntax

```
extern unsigned char _subborrow_u32(unsigned char b_in, unsigned int src1, unsigned int
src2, unsigned int *diff_out);
```

```
extern unsigned char _subborrow_u64(unsigned char b_in, unsigned __int64 src1, unsigned
__int64 src2, unsigned __int64 *diff_out);
```

Parameters

b_in	Borrow-in value for addition operation
src1	32/64 bit source integer for addition operation
src2	32/64 bit source integer for subtraction operation
**diff_out*	Pointer to memory location where result is stored

Description

Computes the sum of a 32/64 bit wide unsigned integer value *src2* and a borrow-in value *b_in* and then subtracts result of the sum from 32/64 bit wide unsigned integer value *src1*. The borrow-in value is considered '1' for any non-zero *b_in* input value, or '0' otherwise. The difference is then stored to a memory location referenced by *diff_out* argument:

```
*diff_out = src1 - (src2 + (b_in !=0 ? 1 : 0))
```

NOTE
This intrinsic does not perform validity checking of the memory address pointed to by *diff_out*, thus it cannot be used to find out if a subtraction produces borrow-out without storing the result of the subtraction.

Returns

Returns borrow-out value generated by subtraction operation. The result of the subtraction is stored into memory location pointed by *diff_out* argument.

Intrinsics that Allow Reading from and Writing to the FS Base and GS Base Registers

There are eight intrinsics that allow reading and writing the value of the FS base and GS base registers at all privilege levels and in 64-bit mode only.

These intrinsics are mapped to corresponding 3rd Generation Intel® Core™ Processor extension instructions.

_readfsbase_u32(), _readfsbase_u64()

Read the value of the FS base register. Both intrinsics are mapped to `RDFSBASE` *instruction.*

Syntax

```
extern unsigned int _readfsbase_u32();
extern unsigned __int64 _readfsbase_u64();
```

Description

These intrinsics read the value of the FS base register.

Returns

The value of the FS base segment register.

_readgsbase_u32(), _readgsbase_u64()

Read the value of the GS base register. Both intrinsics are mapped to `RDGSBASE` instruction.

Syntax

```
extern unsigned int _readgsbase_u32();
extern unsigned int _readgsbase_u32();
```

Description

These intrinsics read the value of the GS base register.

Returns

The value of the GS base segment register.

_writefsbase_u32(), _writefsbase_u64()

Write the value to the FS base register. Both intrinsics are mapped to `WRFSBASE` instruction.

Syntax

```
extern void _writefsbase_u32(int 32 val);
extern void _writefsbase_u64(unsigned __int64 val);
```

Arguments

val	the value to be written to the FS base register

Description

These intrinsics write the given value to the FS segment base register.

_writegsbase_u32(), _writegsbase_u64()

Write the value to the GS base register. Both intrinsics are mapped to `WRGSBASE` instruction.

Syntax

```
_writegsbase_u32(int 32 val)
extern void _writegsbase_u64(unsigned __int64 val);
```

Arguments

val	the value to be written to the GS base register

Description

These intrinsics write the given value to the GS segment base register.

Intrinsics for Intel® Advanced Vector Extensions 2 (Intel® AVX2)

Intel® Advanced Vector Extensions 2 (Intel® AVX2) extends Intel® Advanced Vector Extensions (Intel® AVX) by promoting most of the 128-bit SIMD integer instructions with 256-bit numeric processing capabilities. The Intel® AVX2 instructions follow the same programming model as the Intel® AVX instructions.

Intel® AVX2 also provides enhanced functionality for broadcast/permute operations on data elements, vector shift instructions with variable-shift count per data element, and instructions to fetch non-contiguous data elements from memory.

Intel® AVX2 intrinsics have vector variants that use `__m128`, `__m128i`, `__m256`, and `__m256i` data types.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The Intel® AVX2 intrinsics are supported on IA-32 and Intel® 64 architectures built from 32nm process technology. They map directly to the Intel® AVX2 new instructions and other enhanced 128-bit SIMD instructions.

Functional Overview

Intel® AVX2 instructions promote the vast majority of 128-bit integer SIMD instruction sets to operate with 256-bit wide YMM registers. Intel® AVX2 instructions are encoded using the VEX prefix and require the same operating system support as Intel® AVX. Generally, most of the promoted 256-bit vector integer instructions follow the 128-bit lane operation, similar to the promoted 256-bit floating-point SIMD instructions in Intel® AVX.

The Intel® AVX2 instructions may be broadly categorized as follows:

- **Intel® AVX complementary integer instructions:** Intel® AVX2 instructions complement the Intel® AVX instructions that are typed for integer operations with a full complement of equivalent instructions for operating with integer data elements.
- **`BROADCAST` and `PERMUTE` instructions:** These instructions provide cross-lane functionality for floating-point and integer operations. In addition, some of the Intel® AVX2 256-bit vector integer instructions promoted from legacy SSE instruction sets also exhibiting cross-lane behavior fall into this category; for example, instructions of the `VPMOVZ`/`VPMOVS` family.
- **`SHIFT` instructions:** Intel® AVX2 vector SHIFT instructions operate with per-element shift count and support data element sizes of 32- and 64-bits.
- **`GATHER` instructions:** The Intel® AVX2 vector GATHER instructions are used for fetching non-contiguous data elements from memory using vector-index memory addressing. They introduce a new memory addressing form consisting of a base register and multiple indices specified by a vector register (`XMM` or `YMM`). Data element sizes of 32- and 64-bits are supported as well as data types for floating-point and integer elements.

Details about the Intel® AVX Intrinsics

Intrinsics for Arithmetic Operations

_mm256_abs_epi8/16/32

Computes the absolute value of the signed packed integer data elements of a given vector. The corresponding Intel® AVX2 instruction is `VPABSB`*,* `VPABSW`*, or* `VPABSD`*.*

Syntax

```
extern __m256i _mm256_abs_epi8(__m256i s1);
```

```
extern __m256i _mm256_abs_epi16(__m256i s1);
```

```
extern __m256i _mm256_abs_epi32(__m256i s1);
```

Arguments

s1	integer source vector used for the operation

Description

Computes the absolute value of each data element, either signed bytes, 16-bit words, or 32-bit integers, of the source vector and stores the UNSIGNED results in the destination vector.

Returns

Result of the operation.

_mm256_add_epi8/16/32/64

Adds signed/unsigned packed 8/16/32/64-bit integer data elements of two vectors. The corresponding Intel® AVX2 instruction is `VPADDB`*,* `VPADDW`*,* `VPADDD`*, or* `VPADDQ`*.*

Syntax

```
extern __m256i _mm256_add_epi8(__m256i s1, __m256i s2);
```

```
extern __m256i _mm256_add_epi16(__m256i s1, __m256i s2);
```

```
extern __m256i _mm256_add_epi32(__m256i s1, __m256i s2);
```

```
extern __m256i _mm256_add_epi64(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Adds packed signed/unsigned 8-, 16-, 32-, or 64-bit integers from source vector *s1* and corresponding bits of source vector *s2* and stores the packed integer result in the destination vector. When an individual result is too large to be represented in 8/16/32/64 bits (overflow), the result is wrapped around and the low 8/16/32/64 bits are written to the destination vector (that is, the carry is ignored).

You must control the range of values operated upon to prevent undetected overflow conditions.

Returns

Result of the addition operation.

_mm256_adds_epi8/16

Adds the signed 8/16-bit integer data elements with saturation of two vectors. The corresponding Intel® AVX2 instruction is `VPADDSB` *or* `VPADDSW`*.*

Syntax

```
extern __m256i _mm256_adds_epi8(__m256i s1, __m256i s2);
```

```
extern __m256i _mm256_adds_epi16(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs a SIMD add of the packed, signed, 8- or 16-bit integer data elements with saturation from the first source vector, *s1*, and corresponding elements of the second source vector, *s2*, and stores the packed integer results in the destination vector. When an individual byte/word result is beyond the range of a signed byte/word integer (that is, greater than 7FH/7FFFH or less than 80H/8000H), the saturated value of 7FH/7FFFH or 80H/8000H, respectively, is written to the destination vector.

Returns

Result of the addition operation.

_mm256_adds_epu8/16

Adds the unsigned 8/16-bit integer data elements with saturation of two vectors. The corresponding Intel® AVX2 instruction is `VPADDUSB` *or* `VPADDUSW`*.*

Syntax

```
extern __m256i _mm256_adds_epu8(__m256i s1, __m256i s2);
```

```
extern __m256i _mm256_adds_epu16(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs a SIMD add of the packed, unsigned, 8- or 16-bit integer data elements with saturation from the first source vector, *s1*, and corresponding elements of the second source vector, *s2*, and stores the packed integer results in the destination vector. When an individual byte/word result is beyond the range of a unsigned byte/word integer (that is, greater than FFH/FFFFH), the saturated value of FFH/FFFFH, respectively, is written to the destination vector.

Returns

Result of the addition operation.

_mm256_sub_epi8/16/32/64

Subtracts signed/unsigned packed 8/16/32/64-bit integer data elements of two vectors. The corresponding Intel® AVX2 instruction is `VPSUBB`*,* `VPSUBW`*,* `VPADDD`*, or* `VPSUBQ`*.*

Syntax

```
extern __m256i _mm256_sub_epi8(__m256i s1, __m256i s2);
extern __m256i _mm256_sub_epi16(__m256i s1, __m256i s2);
extern __m256i _mm256_sub_epi32(__m256i s1, __m256i s2);
extern __m256i _mm256_sub_epi64(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Subtracts packed signed/unsigned 8-, 16-, 32-, or 64-bit integers of the second source vector *s2* from corresponding bits of the first source vector *s1* and stores the packed integer result in the destination vector. When an individual result is too large to be represented in 8/16/32/64 bits (overflow), the result is wrapped around and the low 8/16/32/64 bits are written to the destination vector (that is, the carry is ignored).

You must control the range of values operated upon to prevent undetected overflow conditions.

Returns

Result of the subtraction operation.

_mm256_subs_epi8/16

Subtracts the signed 8/16-bit integer data elements with saturation of two vectors. The corresponding Intel® AVX2 instruction is `VPSUBSB` *or* `VPSUBSW`*.*

Syntax

```
extern __m256i _mm256_subs_epi8(__m256i s1, __m256i s2);
extern __m256i _mm256_subs_epi16(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs a SIMD subtract of the packed, signed, 8- or 16-bit integer data elements with saturation of the second source vector *s2* from the corresponding elements of the first source vector *s1* and stores the packed integer results in the destination vector. When an individual byte/word result is beyond the range of a signed byte/word integer (that is, greater than 7FH/7FFFH or less than 80H/8000H), the saturated value of 7FH/7FFFH or 80H/8000H, respectively, is written to the destination vector.

Returns

Result of the subtraction operation.

_mm256_subs_epu8/16

Subtracts the unsigned 8/16-bit integer data elements with saturation of two vectors. The corresponding Intel® AVX2 instruction is `VPSUBUSB` *or* `VPSUBUSW`*.*

Syntax

```
extern __m256i _mm256_subs_epu8(__m256i s1, __m256i s2);
```

```
extern __m256i _mm256_subs_epu16(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs a SIMD subtract of the packed, unsigned, 8- or 16-bit integer data elements with saturation of the second source vector *s2* from the corresponding elements of the first source vector *s1* and stores the packed integer results in the destination vector. When an individual byte/word result is less than zero (that is, 00H/0000H), the saturated value of 00H/0000H is written to the destination vector.

Returns

Result of the subtraction operation.

_mm256_avg_epu8/16

Computes the average of unsigned 8/16-bit integer data elements of two vectors. The corresponding Intel® AVX2 instruction is `VPAVGB` *or* `VPAVGW`*.*

Syntax

```
extern __m256i _mm256_avg_epu8(__m256i s1, __m256i s2);
```

```
extern __m256i _mm256_avg_epu16(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs a SIMD average of the packed unsigned integers from source vector *s2* and source vector *s1* and stores the results in the destination vector. For each corresponding pair of data elements in the first and second vectors, the elements are added together, a 1 is added to the temporary sum, and that result is shifted right by one bit position.

Returns

Result of the operation.

_mm256_hadd_epi16/32

Horizontally adds adjacent signed packed 16/32-bit integer data elements of two vectors. The corresponding Intel® AVX2 instruction is `VPHADDW` *or* `VPHADDD`*.*

Syntax

```
extern __m256i _mm256_hadd_epi16(__m256i s1, __m256i s2);
```

```
extern __m256i _mm256_hadd_epi32(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Adds two adjacent 16- or 32-bit signed integers horizontally from source vectors, *s1* and *s2* and packs the 16 or 32-bit signed results to the destination vector.

Horizontal addition of two adjacent data elements of the low 16- or 32-bytes of the first and second source vectors are packed into the low 16- or 32-bytes of the destination vector. Horizontal addition of two adjacent data elements of the high 16- or 32-bytes of the first and second source vectors are packed into the high 16- or 32-bytes of the destination vector.

Returns

Result of the horizontal addition operation.

_mm256_hadds_epi16

Horizontally adds adjacent signed packed 16-bit integer data elements of two vectors with saturation. The corresponding Intel® AVX2 instruction is `VPHADDSW`*.*

Syntax

```
extern __m256i _mm256_hadds_epi16(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Adds two adjacent, signed 16-bit integers horizontally from the source vectors *s1* and *s2*, saturates the signed results, and packs the signed, saturated 16-bit results to the destination vector.

Returns

Result of the horizontal addition operation with saturation.

_mm256_hsub_epi16/32

Horizontally subtracts adjacent signed packed 16/32-bit integer data elements of two vectors. The corresponding Intel® AVX2 instruction is `VPHSUBW` *or* `VPHSUBD`*.*

Syntax

```
extern __m256i _mm256_hsub_epi16(__m256i s1, __m256i s2);
```

```
extern __m256i _mm256_hsub_epi32(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs horizontal subtraction on each adjacent pair of 16- or 32-bit signed integers by subtracting the most significant word from the least significant word of each pair source vectors *s2* and *s2*, and packs the signed 16- or 32-bit results to the destination vector.

Returns

Result of the horizontal subtraction operation.

_mm256_hsubs_epi16

Horizontally subtracts adjacent signed packed 16-bit integer data elements of two vectors with saturation. The corresponding Intel® AVX2 instruction is `VPHSUBSW`*.*

Syntax

```
extern __m256i _mm256_hsubs_epi16(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs horizontal subtraction on each adjacent pair of 16-bit signed integers by subtracting the most significant word from the least significant word of each pair in source vectors *s1* and *s2*. The signed, saturated 16-bit results are packed to the destination vector.

Returns

Result of the horizontal subtraction operation with saturation.

_mm256_madd_epi16

Multiplies signed packed 16-bit integer data elements of two vectors. The corresponding Intel® AVX2 instruction is `VPMADDW`*.*

Syntax

```
extern __m256i _mm256_madd_epi16(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Multiplies individual, signed 16-bit integers of source vector *s1* by the corresponding signed 16-bit integers of source vector *s2*, producing temporary, signed, 32-bit [doubleword] results. The adjacent doubleword results are then summed and stored in the destination vector.

For example, the corresponding low-order words `(15:0)` and `(31-16)` in *s2* and *s1* vectors are multiplied, and the doubleword results are added together and stored in the low doubleword of the destination vector `(31-0)`. The same operation is performed on the other pairs of adjacent words.

Returns

Result of the multiplication operation.

_mm256_maddubs_epi16

Multiplies unsigned packed 16-bit integer data elements of one vector with signed elements of second vector. The corresponding Intel® AVX2 instruction is `VPMADDUBSW`*.*

Syntax

```
extern __m256i _mm256_maddubs_epi16(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Multiplies vertically each unsigned byte of source vector *s1* with the corresponding signed byte of source vector *s2*, producing intermediate, signed 16-bit integers. Each adjacent pair of signed words is added, and the saturated result is packed to the destination vector.

For example, the lowest-order bytes (bits `7:0`) in *s1* and *s2* vectors are multiplied and the intermediate signed word result is added with the corresponding intermediate result from the 2nd lowest-order bytes (bits `15:8`) of the vectors. The sign-saturated result is stored in the lowest word of the destination vector (`15:0`). The same operation is performed on the other pairs of adjacent bytes.

Returns

Result of the multiplication operation.

_mm256_mul_epi32

Multiplies two vectors with packed doubleword signed integer values. The corresponding Intel® AVX2 instruction is `VPMULDQ`*.*

Syntax

```
extern __m256i _mm256_mul_epi32(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Multiplies the value of packed signed doubleword integer in source vector *s1* by the value in source vector *s2* and stores the result in the destination vector.

When a quadword result is too large to be represented in 64 bits (overflow), the result is wrapped around and the low 64 bits are written to the destination element (that is, the carry is ignored).

Returns

Result of the multiplication operation.

_mm256_mul_epu32

Multiplies two vectors with packed doubleword unsigned integer values. The corresponding Intel® AVX2 instruction is `VPMULUDQ`*.*

Syntax

```
extern __m256i _mm256_mul_epu32(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Multiplies the value of packed unsigned doubleword integer in source vector *s1* by the value in source vector *s2* and stores the result in the destination vector.

When a quadword result is too large to be represented in 64 bits (overflow), the result is wrapped around and the low 64 bits are written to the destination element (that is, the carry is ignored).

Returns

Result of the multiplication operation.

_mm256_mulhi_epi16

Multiplies signed packed 16/32-bit integer data elements of two vectors and stores high bits. The corresponding Intel® AVX2 instruction is `VPMULHW`*.*

Syntax

```
extern __m256i _mm256_mulhi_epi16(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs a SIMD signed multiply of the packed signed 16-bit integers in source vectors *s1* and *s2* and stores the high 16 bits of each intermediate 32-bit result in the destination vector.

Returns

Result of the multiplication operation.

_mm256_mulhi_epu16

Multiplies unsigned packed 16/32-bit integer data elements of two vectors and stores high bits. The corresponding Intel® AVX2 instruction is `VPMULHUW`*.*

Syntax

```
extern __m256i _mm256_mulhi_epu16(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs a SIMD unsigned multiply of the packed unsigned 16-bit integers in source vectors *s1* and *s2* and stores the high 16 bits of each intermediate 32-bit result in the destination vector.

Returns

Result of the multiplication operation.

_mm256_mullo_epi16/32

Multiplies signed packed 16/32-bit integer data elements of two vectors and stores low bits. The corresponding Intel® AVX2 instruction is `VPMULLW` *or* `VPMULLD`*.*

Syntax

```
extern __m256i _mm256_mullo_epi16(__m256i s1, __m256i s2);

extern __m256i _mm256_mullo_epi32(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs a SIMD signed multiply of the packed signed 16- or 32-bit integers in source vectors *s1* and *s2* and stores the low 16- or 32-bits of each intermediate 32- or 64-bit result in the destination vector.

Returns

Result of the multiplication operation.

_mm256_mulhrs_epi16

Multiplies extended packed unsigned integers of two vectors with round and scale. The corresponding Intel® AVX2 instruction is `VPMULHRSW`.

Syntax

```
extern __m256i _mm256_mulhrs_epi16(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Vertically multiplies each signed 16-bit integer from *s1*vector with the corresponding signed 16-bit integer of *s2* vector, producing intermediate, signed 32-bit integers. Each intermediate 32-bit integer is truncated to the 18 most-significant-bits. Rounding is performed by adding 1 to the least-significant-bit of the 18-bit intermediate result.

The final result is obtained by selecting the 16 bits immediately to the right of the most-significant-bit of each 18-bit intermediate result and packing them to the destination operand.

Returns

Result of the multiply, round, and scale operation.

_mm256_sign_epi8/16/32

Changes the sign of elements in one source vector depending on the sign of corresponding element in other source vector. The corresponding Intel® AVX2 instruction is `VPSIGNB, VPSIGNW, or VPSIGND`.

Syntax

```
extern __m256i _mm256_sign_epi8(__m256i s1, __m256i s2);

extern __m256i _mm256_sign_epi16(__m256i s1, __m256i s2);

extern __m256i _mm256_sign_epi32(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Modifies the sign of data elements in the source vector *s1* depending on the sign of corresponding element in vector *s2* as follows:

- If sign of data element in *s2* vector is < 0 then the sign of corresponding data element in vector *s1* is made negative.
- If sign of data element in *s2* vector is > 0 then the sign of corresponding data element in vector *s1* is left unchanged.
- If the data element in *s2* vector is = 0 then the corresponding data element in vector *s1* is set to 0.

The `_mm256_sign_epi8` intrinsic operates on 8-bit signed bytes. The `_mm256_sign_epi16` intrinsic operates on 16-bit signed words. The `_mm256_sign_epi32` intrinsic operates on 32-bit signed integers.

Returns

Result of the operation.

_mm256_mpsadbw_epu8

Performs multiple sum of absolute differences on extended packed unsigned integer values ofs two vectors. The corresponding Intel® AVX2 instruction is `VMPSADBW`*.*

Syntax

```
extern __m256i _mm256_mpsadbw_epu8(__m256i s1, __m256i s2, const int mask);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation
mask	integer constant specifying offset

Description

Performs multiple sum operations of the absolute difference of blocks of four packed unsigned bytes of vector *s2* with sequential blocks of four packed unsigned bytes in vector *s1*. The offset granularity in both vectors is 32 bits.

The sum-absolute-difference (SAD) operation is repeated 16 times by the intrinsic between the *s2* vector with a fixed offset and a variable *s1* vector where the offset is shifted by eight bits for each SAD operation. The integer constant specified in *mask* provides bit fields that specify the initial offset for *s2* and *s1* vectors. Each 16-bit result of eight SAD operations is written to the respective word in the result vector.

Returns

Result of the multiple sum-absolute-difference operation.

_mm256_sad_epu8

Computes sum of absolute differences between extended packed unsigned values of two vectors. The corresponding Intel© AVX2 instruction is `VPSADBW`.

Syntax

```
extern __m256i _mm256_sad_epu8(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Computes the absolute value of the difference of packed groups of eight unsigned byte integers from the source vectors *s1* and *s2*. Four blocks of eight differences are stored at specific locations in the destination vector. Remaining bits in the destination vector are set to zero.

Returns

Result of the single sum-absolute-difference operation.

Intrinsics for Arithmetic Shift Operations

_mm256_sra_epi16/32

Arithmetic shift of word/doubleword elements to right according to specified number. The corresponding Intel© AVX2 instruction is `VPSRAW`*, or* `VPSRAD`.

Syntax

```
extern __m256i _mm256_sra_epi16(__m256i s1, __m128i count);
extern __m256i _mm256_sra_epi32(__m256i s1, __m128i count);
```

Arguments

s1	integer source vector used for the operation
count	128-bit memory location used for the operation

Description

Performs an arithmetic shift of bits in the individual data elements (16-bit word or 32-bit doubleword) in the first source vector *s1* to the right by the number of bits specified in *count*. The empty high-order bits are filled with the initial value of the sign bit. If the value specified by *count* is greater than 15/31/63 (depending on the intrinsic being used), the destination vector is filled with the initial value of the sign bit.

The *count* argument is a 128-bit memory location. Note that only the first 64-bits of a 128-bit count operand are checked to compute the count.

Returns

Result of the right-shift operation.

_mm256_srai_epi16/32

Arithmetic shift of word/doubleword elements to right according to specified number. The corresponding Intel® AVX2 instruction is `VPSRAW` or `VPSRAD`.

Syntax

```
extern __m256i _mm256_srai_epi16(__m256i s1, const int count);
extern __m256i _mm256_srai_epi32(__m256i s1, const int count);
```

Arguments

s1	integer source vector used for the operation
count	8-bit immediate used for the operation

Description

Performs an arithmetic shift of 16-bit [word] or 32-bit [doubleword] elements within a 128-bit lane of source vector *s1* to the right by the number of bits specified in *count*. The empty high-order bits are filled with the initial value of the sign bit. If the value specified by *count* is greater than 15 or 31, the whole destination vector is filled with the initial value of the sign bit. The *count* argument is an 8-bit immediate.

Returns

Result of the right-shift operation.

_mm256_srav_epi32

Arithmetic shift of doubleword elements to right according variable values. The corresponding Intel® AVX2 instruction is `VPSRAVD`.

Syntax

```
extern __m256i _mm256_srav_epi32(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector providing variable values for shift operation

Description

Performs an arithmetic shift of 32 bits (doublewords) in the individual data elements in source vector *s1* to the right by the count value of corresponding data elements in source vector *s2*. As the bits in the data elements are shifted right, the empty high-order bits are filled with the initial value of the sign bit.

The count values are specified individually in each data element of the second source vector. If the unsigned integer value specified in the respective data element of the second source vector is greater than 31 (for a doubleword), then the destination data elements are filled with the initial value of the sign bit.

Returns

Result of the right-shift operation.

_mm_srav_epi32

Arithmetic shift of doubleword elements to right according variable values. The corresponding Intel® AVX2 instruction is `VPSRAVD`.

Syntax

```
extern __m128i _mm_srav_epi32(__m128i s1, __m128i s2);
```

Arguments

s1	128-bit integer source vector used for the operation
s2	128-bit integer source vector providing variable values for shift operation

Description

Performs an arithmetic shift of the 32 bits (doublewords) in the individual data elements in source vector *s1* to the right by the count value of corresponding data elements in source vector *s2*. As the bits in the data elements are shifted right, the empty high-order bits are filled with the initial value of the sign bit.

The count values are specified individually in each data element of the second source vector. If the unsigned integer value specified in the respective data element of the second source vector is greater than 31 (for a doubleword), then the destination data elements are filled with the initial value of the sign bit.

Returns

Result of the right-shift operation.

Intrinsics for Blend Operations

_mm_blend_epi32, _mm256_blend_epi16/32

Conditionally blends data elements of source vector depending on bits in a mask. The corresponding Intel® AVX2 instruction is `VPBLENDD` or `VPBLENDW`.

Syntax

```
extern __m128i _mm_blend_epi32(__m128i s1, __m128i s2, const int mask);

extern __m256i _mm256_blend_epi16(__m256i s1, __m256i s2, const int mask);

extern __m256i _mm256_blend_epi32(__m256i s1, __m256i s2, const int mask);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation
mask	8-bit immediate used for the operation

Description

Performs a blend operation by conditionally copying 16/32-bit [word/doubleword] elements from source vectors *s2* and *s1*, depending on mask bits defined in *mask*. The mask bits are the least significant 8 bits in *mask* when the 256-bit intrinsics, `_mm256_blend_epi16`/`_mm256_blend_epi32`, are used, and 4 bits when the 128-bit intrinsic, `_mm_blend_epi32`, is used.

Each word/doubleword element of the destination vector is copied from the corresponding word/doubleword element in *s2* if a mask bit is 1, or is copied from the corresponding word/doubleword element in *s1* if a mask bit is 0.

Returns

Result of the blend operation.

_mm256_blendv_epi8

Conditionally blends word elements of source vector depending on bits in a mask vector. The corresponding Intel® AVX2 instruction is `VPBLENDVB`*.*

Syntax

```
extern __m256i _mm256_blendv_epi8(__m256i s1, __m256i s2, __m256i mask);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation
mask	integer vector used for the operation

Description

Performs a blend operation by conditionally copying 8-bit byte elements from source vectors *s2* and *s1*, depending on mask bits defined in *mask* vector. The mask bits are the most significant bit in each byte element of *mask.*

Each byte element of the destination vector is copied from the corresponding byte element in *s2* if a mask bit is 1, or the corresponding byte element in *s1* if a mask bit is 0.

Returns

Result of the blend operation.

Intrinsics for Bitwise Operations

_mm256_and_si256

Performs bitwise logical `AND` *operation on signed integer vectors. The corresponding Intel® AVX2 instruction is* `VPAND`*.*

Syntax

```
extern __m256i _mm256_and_si256(__m256i s1, __m256i s2);
```

Arguments

s1	signed integer vector used for the operation
s2	signed integer vector also used for the operation

Description

Performs a bitwise logical AND operation of the signed integer elements of source vector *s1* and corresponding elements in source vector *s2*, and stores the result in the destination vector. If the corresponding bits of the first and second vectors are 1, each bit of the result is set to 1, otherwise it is set to 0.

Returns

Result of the bitwise logical `AND` operation.

_mm256_andnot_si256

Performs bitwise logical `AND NOT` operation on signed integer vectors. The corresponding Intel® AVX2 instruction is `VPANDN`.

Syntax

```
extern __m256i _mm256_andnot_si256(__m256i s1, __m256i s2);
```

Arguments

s1	signed integer vector used for the operation
s2	signed integer vector also used for the operation

Description

Performs a bitwise logical NOT operation on source vector *s1* then performs bitwise AND with source vector *s2* and stores the result in the destination vector. If the corresponding bit in the first vector is 0 and the corresponding bit in the second vector is 1, each bit of the result is set to 1, otherwise it is set to 0.

Returns

Result of the bitwise logical `AND NOT` operation.

_mm256_or_si256

Performs bitwise logical `OR` operation on signed integer vectors. The corresponding Intel® AVX2 instruction is `VPOR`.

Syntax

```
extern __m256i _mm256_or_si256(__m256i s1, __m256i s2);
```

Arguments

s1	signed integer vector used for the operation
s2	signed integer vector also used for the operation

Description

Performs a bitwise logical OR operation of the signed integer elements of source vector *s2* and the corresponding elements in source vector *s1* and stores the result in the destination vector. If either of the corresponding bits of the first and second vectors are 1, each bit of the result is set to 1, otherwise it is set to 0.

Returns

Result of the bitwise logical `OR` operation.

_mm256_xor_si256

Performs bitwise logical `XOR` *operation on signed integer vectors. The corresponding Intel® AVX2 instruction is* `VPXOR`*.*

Syntax

```
extern __m256i _mm256_xor_si256(__m256i s1, __m256i s2);
```

Arguments

s1	signed integer vector used for the operation
s2	signed integer vector also used for the operation

Description

Performs a bitwise logical `XOR` operation of the signed integer elements of source vector *s2* and the corresponding elements in source vector *s1* and stores the result in the destination vector. If the corresponding bits of the first and second vectors differ, each bit of the result is set to 1, otherwise it is set to 0.

Returns

Result of the bitwise logical `XOR` operation.

Intrinsics for Broadcast Operations

_mm_broadcastss_ps, _mm256_broadcastss_ps

Take the low packed single-precision floating-point data element from the source operand and broadcast to all elements of the result vector. The corresponding Intel® AVX2 instruction is `VBROADCASTSS`*.*

Syntax

```
extern __m128 _mm_broadcastss_ps(__m128 val);
extern __m256 _mm256_broadcastss_ps(__m128 val);
```

Arguments

val	__m128 vector containing the 32-bit element to be broadcasted

Description

Takes the low packed single-precision floating-point (float32) data element from the source operand and broadcasts it to all elements of the result vector. The source operand is `__m128`; only the low 32 bits of this operand are broadcasted.

Returns

Return result of the broadcast operation.

_mm256_broadcastsd_pd

Takes the low packed double-precision floating-point data element from the source operand and broadcast to all elements of the result vector. The corresponding Intel® AVX2 instruction is `VBROADCASTSD`.

Syntax

```
extern __m256d _mm256_broadcastsd_pd(__m128d val);
```

Arguments

val	__m128 vector containing the 64-bit element to be broadcasted

Description

Takes the low packed double-precision floating-point (float64) data element from the source operand and broadcasts it to all elements of the result vector. The source operand is `__m128d`; only the low 64 bits of this operand are broadcasted.

The 128-bit version of this intrinsics is `_mm_broadcastsd_pd`. The intrinsic's syntax is `extern __m128d _mm_broadcastsd_pd(__m128d val);` This intrinsic is an alias for `_mm_movedup_pd()` intrinsic. Please, see Double-precision Floating-point Vector Intrinsics for details.

Returns

Return result of the broadcast operation.

_mm_broadcastb_epi8, _mm256_broadcastb_epi8

Take byte elements from the source operand and broadcast to all elements of the result vector. The corresponding Intel® AVX2 instruction is `VPBROADCASTB`.

Syntax

```
extern __m128i _mm_broadcastb_epi8(__m128i val);

extern __m256i _mm256_broadcastb_epi8(__m128i val);
```

Arguments

val	__m128i vector containing the elements to be broadcasted

Description

Takes a byte integer in the low bits of the source operand and broadcasts to all elements of the result vector.

Returns

Returns result of the broadcast operation.

_mm_broadcastw_epi16, _mm256_broadcastw_epi16

Take word elements from the source operand and broadcast to all elements of the result vector. The corresponding Intel© AVX2 instruction is `VPBROADCASTW`.

Syntax

```
extern __m128i _mm_broadcastw_epi16(__m128i val);
extern __m256i _mm256_broadcastw_epi16(__m128i val);
```

Arguments

val	__m128i vector containing the elements to be broadcasted

Description

Takes a word integer in the low bits of the source operand and broadcasts to all eight or sixteen elements of the result vector.

Returns

Returns result of the broadcast operation.

_mm_broadcastd_epi32, _mm256_broadcastd_epi32

Take doublewords from the source operand and broadcast to all elements of the result vector. The corresponding Intel© AVX2 instruction is `VPBROADCASTD`.

Syntax

```
extern __m128i _mm_broadcastd_epi32(__m128i val);
extern __m256i _mm256_broadcastd_epi32(__m128i val);
```

Arguments

val	__m128i vector containing 32-bit element to be broadcasted

Description

Takes a dword integer in the low bits of the source operand and broadcasts to all elements of the result vector.

Returns

Returns result of the broadcast operation.

_mm_broadcastq_epi64, _mm256_broadcastq_epi64

Take qwords from the source operand and broadcast to all elements of the result vector. The corresponding Intel® AVX2 instruction is `VPBROADCASTQ`.

Syntax

```
extern __m128i _mm_broadcastq_epi64(__m128i val);
extern __m256i _mm256_broadcastq_epi64(__m128i val);
```

Arguments

val	__m128i vector containing 64-bit element to be broadcasted

Description

Takes a qword integer in the low bits of the source operand and broadcasts to all elements of the result vector.

Returns

Returns result of the broadcast operation.

_mm256_broadcastsi128_si256

Takes 128-bit data from the source operand and broadcasts it to all 128-bit elements of the result 256-bit vector. The corresponding Intel® AVX2 instructions are `VBROADCASTI128` *and* `VPERM2I128`.

Syntax

```
extern __m256i _mm256_broadcastsi128_si256(__m128i val);
```

Arguments

val	the value to be broadcasted

Description

Takes 128-bit data from the source operand and broadcasts it to all 128-bit elements of the result 256-bit vector.

Returns

Returns result of the broadcast operation.

Intrinsics for Compare Operations

_mm256_cmpeq_epi8/16/32/64

Compares packed bytes/words/doublewords/quadwords of two source vectors. The corresponding Intel® AVX2 instruction is `VPCMPEQB`, `VPCMPEQW`, `VPCMPEQD`, *or* `VPCMPEQQ`.

Syntax

```
extern __m256i _mm256_cmpeq_epi8(__m256i s1, __m256i s2);
extern __m256i _mm256_cmpeq_epi16(__m256i s1, __m256i s2);
extern __m256i _mm256_cmpeq_epi32(__m256i s1, __m256i s2);
extern __m256i _mm256_cmpeq_epi64(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs a SIMD compare for equality of packed bytes, words, doublewords, or quadwords in source vectors *s1* and *s2*. If a pair of data elements is equal, the corresponding data element in the destination vector is set to all 1s. If a pair of data elements is unequal, the corresponding data element in the destination vector is set to 0.

Returns

Destination vector with result of the compare equal operation.

_mm256_cmpgt_epi8/16/32/64

Compares packed bytes/words/doublewords/ quadwords of two source vectors. The corresponding Intel® AVX2 instruction is `VPCMPGTB`*,* `VPCMPGTW`*,* `VPCMPGTD`*, or* `VPCMPGTQ`*.*

Syntax

```
extern __m256i _mm256_cmpgt_epi8(__m256i s1, __m256i s2);
extern __m256i _mm256_cmpgt_epi16(__m256i s1, __m256i s2);
extern __m256i _mm256_cmpgt_epi32(__m256i s1, __m256i s2);
extern __m256i _mm256_cmpgt_epi64(__m256i s1, __m256i s2);
```

Arguments

s1	integer destination vector used for the operation
s2	integer source vector used for the operation

Description

Performs a SIMD signed compare to determine which of the data elements [packed bytes, words, doublewords, or quadwords] in destination vector *s1* is greater than the corresponding element in the source vector *s2*.

For each pair of data elements in *s1* and *s2*, if the *s1* data element is greater than the corresponding element in *s2*, then the corresponding element in the destination vector is set to all 1s. If the *s1* data element is less than the corresponding data element in *s2*, then the corresponding data element in destination vector is set to all 0s.

If the data elements are equal, the destination vector is set to 0.

Returns

Destination vector with result of the compare greater-than operation.

_mm256_max_epi8/16/32

Determines the maximum value between two vectors with packed signed byte/word/doubleword integers. The corresponding Intel® AVX2 instruction is `VPMAXSB`*,* `VPMAXSW`*, or* `VPMAXSD`*.*

Syntax

```
extern __m256i _mm256_max_epi8(__m256i s1, __m256i s2);
extern __m256i _mm256_max_epi16(__m256i s1, __m256i s2);
extern __m256i _mm256_max_epi32(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs a SIMD compare of the packed signed byte, word, or doubleword integers in source vectors *s1* and *s2* and returns the maximum value for each pair of integers to the destination vector.

Returns

Destination vector with result of the compare operation.

_mm256_max_epu8/16/32

Determines the maximum value between two vectors with packed unsigned byte/word/doubleword integers. The corresponding Intel® AVX2 instruction is `VPMAXUB`*,* `VPMAXUW`*, or* `VPMAXUD`*.*

Syntax

```
extern __m256i _mm256_max_epu8(__m256i s1, __m256i s2);
extern __m256i _mm256_max_epu16(__m256i s1, __m256i s2);
extern __m256i _mm256_max_epu32(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs a SIMD compare of the packed unsigned byte, word, or doubleword integers in source vectors *s1* and *s2* and returns the maximum value for each pair of integers to the destination vector.

Returns

Destination vector with result of the compare operation.

_mm256_min_epi8/16/32

Determines the minimum value between two vectors with packed signed byte/word/doubleword integers. The corresponding Intel® AVX2 instruction is `VPMINSB`*,* `VPMINSW`*, or* `VPMINSD`*.*

Syntax

```
extern __m256i _mm256_min_epi8(__m256i s1, __m256i s2);
extern __m256i _mm256_min_epi16(__m256i s1, __m256i s2);
extern __m256i _mm256_min_epi32(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs a SIMD compare of the packed signed byte, word, or doubleword integers in source vectors *s1* and *s2* and returns the minimum value for each pair of integers to the destination vector.

Returns

Destination vector with result of the compare operation.

_mm256_min_epu8/16/32

Determines the minimum value between two vectors with packed unsigned byte/word/doubleword integers. The corresponding Intel® AVX2 instruction is `VPMINUB`*,* `VPMINUW`*, or* `VPMINUD`*.*

Syntax

```
extern __m256i _mm256_min_epu8(__m256i s1, __m256i s2);
extern __m256i _mm256_min_epu16(__m256i s1, __m256i s2);
extern __m256i _mm256_min_epu32(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation

Description

Performs a SIMD compare of the packed unsigned byte, word, or doubleword integers in source vectors *s1* and *s2* and returns the minimum value for each pair of integers to the destination vector.

Returns

Destination vector with result of the compare operation.

Intrinsics for Fused Multiply Add Operations

_mm_fmadd_pd, _mm256_fmadd_pd

Multiply-adds packed double-precision floating-point values using three float64 vectors. The corresponding FMA instruction is `VFMADD<XXX>PD`*, where XXX could be 132, 213, or 231.*

Syntax

For 128-bit vector

```
extern __m128d _mm_fmadd_pd(__m128d a, __m128d b, __m128d c);
```

For 256-bit vector

```
extern __m256d _mm256_fmadd_pd(__m256d a, __m256d b, __m256d c);
```

Arguments

a	float64 vector used for the operation
b	float64 vector also used for the operation
c	float64 vector also used for the operation

Description

Performs a set of SIMD multiply-add computation on packed double-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and the infinite precision intermediate results are added to corresponding values in the third operand, after which the final results are rounded to the nearest float64 values.

The compiler defaults to using the `VFMADD213PD` instruction and uses the other forms `VFMADD132PD` or `VFMADD231PD` only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-add operation.

_mm_fmadd_ps, _mm256_fmadd_ps

Multiply-adds packed single-precision floating-point values using three float32 vectors. The corresponding FMA instruction is `VFMADD<XXX>PS`*, where XXX could be 132, 213, or 231.*

Syntax

For 128-bit vector

```
extern __m128 _mm_fmadd_ps(__m128 a, __m128 b, __m128 c);
```

For 256-bit vector

```
extern __m256 _mm256_fmadd_ps(__m256 a, __m256 b, __m256 c);
```

Arguments

a	float32 vector used for the operation
b	float32 vector also used for the operation
c	float32 vector also used for the operation

Description

Performs a set of SIMD multiply-add computation on packed single-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and the infinite precision intermediate results are added to corresponding values in the third operand, after which the final results are rounded to the nearest float32 values.

The compiler defaults to using the `VFMADD213PS` instruction and uses the other forms `VFMADD132PS` or `VFMADD231PS` only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-add operation.

_mm_fmadd_sd

Multiply-adds scalar double-precision floating-point values using three float64 vectors. The corresponding FMA instruction is `VFMADD<XXX>SD`*, where XXX could be 132, 213, or 231.*

Syntax

```
extern __m128d _mm_fmadd_sd(__m128d a, __m128d b, __m128d c);
```

Arguments

a	float64 vector used for the operation
b	float64 vector also used for the operation
c	float64 vector also used for the operation

Description

Performs a set of scalar SIMD multiply-add computation on scalar double-precision floating-point values in the low 32-bits of three source operands, *a*, *b*, and *c*. The float64 values in two operands, *a* and *b*, are multiplied and the infinite precision intermediate result is obtained. The float64 value in the third operand, *c*, is added to the infinite precision intermediate result. The final result is rounded to the nearest float64 value.

The compiler defaults to using the `VFMADD213SD` instruction and uses the other forms `VFMADD132SD` or `VFMADD231SD` only if a low level optimization decides it is useful/necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-add operation.

_mm_fmadd_ss

Multiply-adds scalar single-precision floating-point values using three float32vectors. The corresponding FMA instruction is `VFMADD<XXX>SS`*, where XXX could be 132, 213, or 231.*

Syntax

```
extern __m128 _mm_fmadd_ss(__m128 a, __m128 b, __m128 c);
```

Arguments

a	float32 vector used for the operation
b	float32 vector also used for the operation
c	float32 vector also used for the operation

Description

Performs a set of scalar SIMD multiply-add computation on scalar single-precision floating-point values in the low 32-bits of three source operands, *a*, *b*, and *c*. The float32 values in two operands, a and b, are multiplied and the infinite precision intermediate result is obtained. The float32 value in the third operand, *c*, is added to the infinite precision intermediate result. The final result is rounded to the nearest float32 value.

The compiler defaults to using the `VFMADD213SS` instruction and uses the other forms `VFMADD132SS` or `VFMADD231SS` only if a low level optimization decides it is useful/necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-add operation.

_mm_fmaddsub_pd, _mm256_fmaddsub_pd

Multiply-adds and subtracts packed double-precision floating-point values using three float64 vectors. The corresponding FMA instruction is `VFMADDSUB<XXX>PD`*, where XXX could be 132, 213, or 231.*

Syntax

For 128-bit vector

```
extern __m128d _mm_fmaddsub_pd(__m128d a, __m128d b, __m128d c);
```

For 256-bit vector

```
extern __m256d _mm256_fmaddsub_pd(__m256d a, __m256d b, __m256d c);
```

Arguments

a	float64 vector used for the operation
b	float64 vector also used for the operation
c	float64 vector also used for the operation

Description

Performs a set of SIMD multiply-add-subtract computation on packed double-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and infinite precision intermediate results are obtained. The odd values in the third operand, `c`, are added to the intermediate results while the even values are subtracted from them. The final results are rounded to the nearest float64 values.

The compiler defaults to using the `VFMADDSUB213PD` instruction and uses the other forms `VFMADDSUB132PD` or `VFMADDSUB231PD` only if a low-level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-add-subtract operation.

_mm_fmaddsub_ps, _mm256_fmaddsub_ps

Multiply-adds and subtracts packed single-precision floating-point values using three float32 vectors. The corresponding FMA instruction is `VFMADDSUB<XXX>PS`*, where XXX could be 132, 213, or 231.*

Syntax

For 128-bit vector

```
extern __m128 _mm_fmaddsub_ps(__m128 a, __m128 b, __m128 c);
```

For 256-bit vector

```
extern __m256 _mm256_fmaddsub_ps(__m256 a, __m256 b, __m256 c);
```

Arguments

a	float32 vector used for the operation
b	float32 vector also used for the operation
c	float32 vector also used for the operation

Description

Performs a set of SIMD multiply-add-subtract computation on packed single-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and infinite precision intermediate results are obtained. The odd values in the third operand, `c`, are added to the intermediate results while the even values are subtracted from them. The final results are rounded to the nearest float32 values.

The compiler defaults to using the `VFMADDSUB213PS` instruction and uses the other forms `VFMADDSUB132PS` or `VFMADDSUB231PS` only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-add-subtract operation.

_mm_fmsub_pd, _mm256_fmsub_pd

Multiply-subtracts packed double-precision floating-point values using three float64 vectors. The corresponding FMA instruction is `VFMSUB<XXX>PD`*, where XXX could be 132, 213, or 231.*

Syntax

For 128-bit vector

```
extern __m128d _mm_fmsub_pd(__m128d a, __m128d b, __m128d c);
```

For 256-bit vector

```
extern __m256d _mm256_fmsub_pd(__m256d a, __m256d b, __m256d c);
```

Arguments

a	float64 vector used for the operation
b	float64 vector also used for the operation
c	float64 vector also used for the operation

Description

Performs a set of SIMD multiply-subtract computation on packed double-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and the infinite precision intermediate results are obtained. From the infinite precision intermediate results, the values in the third operand, `c`, are subtracted. The final results are rounded to the nearest float64 values.

The compiler defaults to using the `VFMSUB213PD` instruction and uses the other forms `VFMSUB132PD` or `VFMSUB231PD` only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-subtract operation.

_mm_fmsub_ps, _mm256_fmsub_ps

Multiply-subtracts packed single-precision floating-point values using three float32 vectors. The corresponding FMA instruction is `VFMSUB<XXX>PS`*, where XXX could be 132, 213, or 231.*

Syntax

For 128-bit vector

```
extern __m128 _mm_fmsub_ps(__m128 a, __m128 b, __m128 c);
```

For 256-bit vector

```
extern __m256 _mm256_fmsub_ps(__m256 a, __m256 b, __m256 c);
```

Arguments

a	float32 vector used for the operation
b	float32 vector also used for the operation

c	float32 vector also used for the operation

Description

Performs a set of SIMD multiply-subtract computation on packed single-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and the infinite precision intermediate results are obtained. From the infinite precision intermediate results, the values in the third operand, `c`, are subtracted. The final results are rounded to the nearest float32 values.

The compiler defaults to using the `VFMSUB213PS` instruction and uses the other forms `VFMSUB132PS` or `VFMSUB231PS` only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-subtract operation.

_mm_fmsub_sd

Multiply-subtracts scalar double-precision floating-point values using three float64 vectors. The corresponding FMA instruction is `VFMSUB<XXX>SD`*, where XXX could be 132, 213, or 231.*

Syntax

```
extern __m128d _mm_fmsub_sd(__m128d a, __m128d b, __m128d c);
```

Arguments

a	float64 vector used for the operation
b	float64 vector also used for the operation
c	float64 vector also used for the operation

Description

Performs a set of scalar SIMD multiply-subtract computation on scalar double-precision floating-point values in the low 64-bits of three source operands, *a*, *b*, and *c*. The float64 values in two operands, a and b, are multiplied and the infinite precision intermediate result is obtained. From the infinite precision intermediate result, the float64 value in the third operand, *c*, is subtracted. The final result is rounded to the nearest float64 value.

The compiler defaults to using the `VFMSUB213SD` instruction and uses the other forms `VFMSUB132SD` or `VFMSUB231SD` only if a low level optimization decides it is useful/necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-subtract operation.

_mm_fmsub_ss

Multiply-subtracts scalar single-precision floating-point values using three float32vectors. The corresponding FMA instruction is `VFMSUB<XXX>SS`*, where XXX could be 132, 213, or 231.*

Syntax

```
extern __m128 _mm_fmsub_ss(__m128 a, __m128 b, __m128 c);
```

Arguments

a	float32 vector used for the operation
b	float32 vector also used for the operation
c	float32 vector also used for the operation

Description

Performs a set of scalar SIMD multiply-subtract computation on scalar single-precision floating-point values in the low 32-bits of three source operands, `a`, `b`, and `c`. The float32 values in two operands, `a` and `b`, are multiplied and the infinite precision intermediate result is obtained. From the infinite precision intermediate result, the float32 value in the third operand, `c`, is subtracted. The final result is rounded to the nearest float32 value.

The compiler defaults to using the `VFMSUB213SS` instruction and uses the other forms `VFMSUB132SS` or `VFMSUB231SS` only if a low level optimization decides it is useful/necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-subtract operation.

_mm_fmsubadd_pd, _mm256_fmsubadd_pd

Multiply-subtracts and adds packed double-precision floating-point values using three float64 vectors. The corresponding FMA instruction is `VFMSUBADD<XXX>PD`*, where XXX could be 132, 213, or 231.*

Syntax

For 128-bit vector

```
extern __m128d _mm_fmsubadd_pd(__m128d a, __m128d b, __m128d c);
```

For 256-bit vector

```
extern __m256d _mm256_fmsubadd_pd(__m256d a, __m256d b, __m256d c);
```

Arguments

a	float64 vector used for the operation
b	float64 vector also used for the operation
c	float64 vector also used for the operation

Description

Performs a set of SIMD multiply-subtract-add computation on packed double-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and infinite precision intermediate results are obtained. The odd values in the third operand, `c`, are subtracted from the intermediate results while the even values are added to them. The final results are rounded to the nearest float64 values.

The compiler defaults to using the `VFMSUBADD213PD` instruction and uses the other forms `VFMSUBADD132PD` or `VFMSUBSADD231PD` only if a low-level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-subtract-add operation.

_mm_fmsubadd_ps, _mm256_fmsubadd_ps

Multiply-subtracts and adds packed single-precision floating-point values using three float32 vectors. The corresponding FMA instruction is `VFMSUBADD<XXX>PS`*, where XXX could be 132, 213, or 231.*

Syntax

For 128-bit vector

```
extern __m128 _mm_fmsubadd_ps(__m128 a, __m128 b, __m128 c);
```

For 256-bit vector

```
extern __m256 _mm256_fmsubadd_ps(__m256 a, __m256 b, __m256 c);
```

Arguments

a	float32 vector used for the operation
b	float32 vector also used for the operation
c	float32 vector also used for the operation

Description

Performs a set of SIMD multiply-subtract-add computation on packed single-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and infinite precision intermediate results are obtained. The odd values in the third operand, `c`, are subtracted from the intermediate results while the even values are added to them. The final results are rounded to the nearest float32 values.

The compiler defaults to using the `VFMSUBADD213PS` instruction and uses the other forms `VFMSUBADD132PS` or `VFMSUBADDS231PS` only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the multiply-add-subtract operation.

_mm_fnmadd_pd, _mm256_fnmadd_pd

Multiply-adds negated packed double-precision floating-point values of three float64 vectors. The corresponding FMA instruction is `VFNMADD<XXX>PD`*, where XXX could be 132, 213, or 231.*

Syntax

For 128-bit vector

```
extern __m128d _mm_fnmadd_pd(__m128d a, __m128d b, __m128d c);
```

For 256-bit vector

```
extern __m256d _mm256_fnmadd_pd(__m256d a, __m256d b, __m256d c);
```

Arguments

a	float64 vector used for the operation
b	float64 vector also used for the operation
c	float64 vector also used for the operation

Description

Performs a set of SIMD negated multiply-add computation on packed double-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and the negated infinite precision intermediate results are added to the values in the third operand, `c`, after which the final results are rounded to the nearest float64 values.

The compiler defaults to using the `VFNMADD213PD` instruction and uses the other forms `VFNMADD132PD` or `VFNMADD231PD` only if a low level optimization decides it as useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the negated multiply-add operation.

_mm_fnmadd_ps, _mm256_fnmadd_ps

Multiply-adds negated packed single-precision floating-point values of three float32 vectors. The corresponding FMA instruction is `VFNMADD<XXX>PS`*, where XXX could be 132, 213, or 231.*

Syntax

For 128-bit vector

```
extern __m128 _mm_fnmadd_ps(__m128 a, __m128 b, __m128 c);
```

For 256-bit vector

```
extern __m256 _mm256_fnmadd_ps(__m256 a, __m256 b, __m256 c);
```

Arguments

a	float64 vector used for the operation
b	float64 vector also used for the operation
c	float64 vector also used for the operation

Description

Performs a set of SIMD negated multiply-add computation on packed single-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and the negated infinite precision intermediate results are added to the values in the third operand, `c`, after which the final results are rounded to the nearest float32 values.

The compiler defaults to using the `VFNMADD213PS` instruction and uses the other forms `VFNMADD132PS` or `VFNMADD231PS` only if a low level optimization decides it as useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the negated multiply-add operation.

_mm_fnmadd_sd

Multiply-adds negated scalar double-precision floating-point values of three float64 vectors. The corresponding FMA instruction is `VFNMADD<XXX>SD`*, where XXX could be 132, 213, or 231.*

Syntax

```
extern __m128d _mm_fnmadd_sd(__m128d a, __m128d b, __m128d c);
```

Arguments

a	float64 vector used for the operation
b	float64 vector also used for the operation
c	float64 vector also used for the operation

Description

Performs a set of scalar SIMD negated multiply-add computation on scalar double-precision floating-point values in the low 64-bits of three source operands, *a*, *b*, and *c*. The float64 values in two operands, *a* and *b*, are multiplied and the negated infinite precision intermediate result obtained is added to the float64 value in the third operand, *c*. The final result is rounded to the nearest float64 value.

The compiler defaults to using the `VFNMADD213SD` instruction and uses the other forms `VFNMADD132SD` or `VFNMADD231SD` only if a low level optimization decides it as useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the negated multiply-add operation.

_mm_fnmadd_ss

Multiply-adds negated scalar single-precision floating-point values of three float32 vectors. The corresponding FMA instruction is `VFNMADD<XXX>SS`*, where XXX could be 132, 213, or 231.*

Syntax

```
extern __m128 _mm_fnmadd_ss(__m128 a, __m128 b, __m128 c);
```

Arguments

a	float64 vector used for the operation
b	float64 vector also used for the operation
c	float64 vector also used for the operation

Description

Performs a set of scalar SIMD negated multiply-add computation on scalar single-precision floating-point values in the low 32-bits of three source operands, *a*, *b*, and *c*. The float32 values in two operands, *a* and *b*, are multiplied and the negated infinite precision intermediate result obtained is added to the float32 value in the third operand, *c*. The final result is rounded to the nearest float32 value.

The compiler defaults to using the `VFNMADD213SS` instruction and uses the other forms `VFNMADD132SS` or `VFNMADD231SS` only if a low level optimization decides it as useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the negated multiply-add operation.

_mm_fnmsub_pd, _mm256_fnmsub_pd

Multiply-subtracts negated packed double-precision floating-point values of three float64 vectors. The corresponding FMA instruction is `VFNMSUB<XXX>PD`*, where XXX could be 132, 213, or 231.*

Syntax

For 128-bit vector

```
extern __m128d _mm_fnmsub_pd(__m128d a, __m128d b, __m128d c);
```

For 256-bit vector

```
extern __m256d _mm256_fnmsub_pd(__m256d a, __m256d b, __m256d c);
```

Arguments

a	float64 vector used for the operation
b	float64 vector also used for the operation
c	float64 vector also used for the operation

Description

Performs a set of SIMD negated multiply-subtract computation on packed double-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and the negated infinite precision intermediate result is obtained. From this intermediate result the value in the third operand, `c`, is subtracted, after which the final results are rounded to the nearest float64 values.

The compiler defaults to using the `VFNMSUB213PD` instruction and uses the other forms `VFNMSUB132PD` or `VFNMSUB231PD` only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the negated multiply-subtract operation.

_mm_fnmsub_ps, _mm256_fnmsub_ps

Multiply-subtracts negated packed single-precision floating-point values of three float32 vectors. The corresponding FMA instruction is `VFNMSUB<XXX>PS`*, where XXX could be 132, 213, or 231.*

Syntax

For 128-bit vector

```
extern __m128 _mm_fnmsub_ps(__m128 a, __m128 b, __m128 c);
```

For 256-bit vector

```
extern __m256 _mm256_fnmsub_ps(__m256 a, __m256 b, __m256 c);
```

Arguments

a	float32 vector used for the operation
b	float32 vector also used for the operation
c	float32 vector also used for the operation

Description

Performs a set of SIMD negated multiply-subtract computation on packed single-precision floating-point values using three source vectors/operands, `a`, `b`, and `c`. Corresponding values in two operands, `a` and `b`, are multiplied and the negated infinite precision intermediate result is obtained. From this intermediate result the value in the third operand, `c`, is subtracted, after which the final results are rounded to the nearest float32 values.

The compiler defaults to using the `VFNMSUB213PS` instruction and uses the other forms `VFNMSUB132PS` or `VFNMSUB231PS` only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the negated multiply-subtract operation.

_mm_fnmsub_sd

Multiply-subtracts negated scalar double-precision floating-point values of three float64 vectors. The corresponding FMA instruction is `VFNMSUB<XXX>SD`*, where XXX could be 132, 213, or 231.*

Syntax

```
extern __m128d _mm_fnmsub_sd(__m128d a, __m128d b, __m128d c);
```

Arguments

a	float64 vector used for the operation
b	float64 vector also used for the operation
c	float64 vector also used for the operation

Description

Performs a set of scalar SIMD negated multiply-subtract computation on scalar double-precision floating-point values in the low 64-bits of three source operands, *a*, *b*, and *c*. The float64 values in two operands, *a* and *b*, are multiplied and the negated infinite precision intermediate result is obtained. From this negated intermediate result, the float64 value in the third operand, *c*, is subtracted. The final result is rounded to the nearest float64 value.

The compiler defaults to using the `VFNMSUB213SD` instruction and uses the other forms `VFNMSUB132SD` or `VFNMSUB231SD` only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the negated multiply-subtract operation.

_mm_fnmsub_ss

Multiply-subtracts negated scalar single-precision floating-point values of three float32 vectors. The corresponding FMA instruction is `VFNMSUB<XXX>SS`*, where XXX could be 132, 213, or 231.*

Syntax

```
extern __m128 _mm_fnmsub_ss(__m128 a, __m128 b, __m128 c);
```

Arguments

a	float32 vector used for the operation
b	float32 vector also used for the operation
c	float32 vector also used for the operation

Description

Performs a set of scalar SIMD negated multiply-subtract computation on scalar single-precision floating-point values in the low 32-bits of three source operands, *a*, *b*, and *c*. The float32 values in two operands, *a* and *b*, are multiplied and the negated infinite precision intermediate result is obtained. From this negated intermediate result, the float32 value in the third operand, *c*, is subtracted. The final result is rounded to the nearest float32 value.

The compiler defaults to using the `VFNMSUB213SS` instruction and uses the other forms `VFNMSUB132SS` or `VFNMSUB231SS` only if a low level optimization decides it is useful or necessary. For example, the compiler could change the default if it finds that another instruction form saves a register or eliminates a move.

Returns

Result of the negated multiply-subtract operation.

Intrinsics for GATHER Operations

_mm_mask_i32gather_pd, _mm256_mask_i32gather_pd

Gathers 2/4 packed double-precision floating point values from memory referenced by the given base address, dword indices and scale, and using the given double-precision FP mask values. The corresponding Intel© AVX2 instruction is `VGATHERDPD`.

Syntax

```
extern __m128d _mm_mask_i32gather_pd(__m128d def_vals, double const * base, __m128i
vindex __m128d vmask, const int scale);
```

```
extern __m256d _mm256_mask_i32gather_pd(__m256d def_vals, double const * base, __m128i
vindex __m256d vmask, const int scale);
```

Arguments

def_vals	the vector of double-precision FP values copied to the destination when the corresponding element of the double-precision FP mask is '0'.
base	the base address used to reference the loaded FP elements.
vindex	the vector of dword indices used to reference the loaded FP elements.
vmask	the vector of FP elements used as a vector mask; only the most significant bit of each data element is used as a mask.
scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics conditionally load 2/4 packed double-precision floating-point values from memory using dword indices according to mask values and updates the destination operand.

Below is the pseudo-code for the intrinsics:

`_mm_mask_i32gather_pd()`:

```
result[63:0] = (vmask[63]==1) ? (mem[base+vindex[31:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem[base+vindex[63:32]*scale]) : (def_vals[127:64]);
```

`_mm256_mask_i32gather_pd()`:

```
result[63:0] = (vmask[63]==1) ? (mem[base+vindex[31:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem[base+vindex[63:32]*scale]) : (def_vals[127:64]);
result[191:128] = (vmask[191]==1) ? (mem[base+vindex[95:64]*scale]) : (def_vals[191:128]);
result[255:192] = (vmask[255]==1) ? (mem[base+vindex[127:96]*scale]) : (def_vals[255:192]);
```

Returns

A 128/256-bit vector with conditionally gathered double-precision FP values.

_mm_i32gather_pd, _mm256_i32gather_pd

Gathers 2/4 packed double-precision floating point values from memory referenced by the given base address, dword indices and scale. The corresponding Intel® AVX2 instruction is `VGATHERDPD`.

Syntax

`extern __m128d _mm_i32gather_pd(double const * base, __m128i vindex, const int scale);`

`extern __m256d _mm256_i32gather_pd(double const * base, __m128i vindex, const int scale);`

Arguments

base	the base address used to reference the loaded FP elements.
vindex	the vector of dword indices used to reference the loaded FP elements.
scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics load 2/4 packed double-precision floating-point values from memory using dword indices and updates the destination operand.

Below is the pseudo-code for the intrinsics:

`_mm_i32gather_pd()`:

```
result[63:0] = mem[base+vindex[31:0]*scale];
result[127:64] = mem[base+vindex[63:32]*scale];
```

`_mm256_i32gather_pd()`:

```
result[63:0] = mem[base+vindex[31:0]*scale];
result[127:64] = mem[base+vindex[63:32]*scale];
result[191:128] = mem[base+vindex[95:64]*scale];
result[255:192] = mem[base+vindex[127:96]*scale];
```

Returns

A 128/256-bit vector with unconditionally gathered double-precision FP values.

_mm_mask_i64gather_pd, _mm256_mask_i64gather_pd

Gathers 2/4 packed double-precision floating point values from memory referenced by the given base address, qword indices and scale, and using the given double precision FP mask values. The corresponding Intel® AVX2 instruction is `VGATHERQPD`.

Syntax

`extern __m128d _mm_mask_i64gather_pd(__m128d def_vals, double const * base, __m128i vindex __m128d vmask, const int scale);`

```
extern __m256d _mm256_mask_i64gather_pd(__m256d def_vals, double const * base, __m128i
vindex __m256d vmask, const int scale);
```

Arguments

def_vals	the vector of double-precision FP values copied to the destination when the corresponding element of the double-precision FP mask is '0'.
base	the base address used to reference the loaded FP elements.
vindex	the vector of qword indices used to reference the loaded FP elements.
vmask	the vector of FP elements used as a vector mask; only the most significant bit of each data element is used as a mask.
scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics conditionally load 2/4 packed double-precision floating-point values from memory using qword indices according to mask values.

Below is the pseudo-code for the intrinsics:

`_mm_mask_i64gather_pd():`

```
result[63:0] = (vmask[63]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[127:64]);
```

`_mm256_mask_i64gather_pd():`

```
result[63:0] = (vmask[63]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[127:64]);
result[191:128] = (vmask[191]==1) ? (mem[base+vindex[191:128]*scale]) : (def_vals[191:128]);
result[255:192] = (vmask[255]==1) ? (mem[base+vindex[255:192]*scale]) : (def_vals[255:192]);
```

Returns

A 128/256-bit vector with conditionally gathered double-precision values.

_mm_i64gather_pd, _mm256_i64gather_pd

Gathers 2/4 packed double-precision floating point values from memory referenced by the given base address, qword indices, and scale. The corresponding Intel® AVX2 instruction is `VGATHERQPD`.

Syntax

```
extern __m128d _mm_i64gather_pd(double const * base, __m128i vindex, const int scale);
```

```
extern __m256d _mm256_mask_i64gather_pd(double const * base, __m128i vindex, const int
scale);
```

Arguments

base	the base address used to reference the loaded FP elements.
vindex	the vector of qword indices used to reference the loaded FP elements.
scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics load 2/4 packed double-precision floating-point values from memory using qword indices and updates the destination operand.

Below is the pseudo-code for the intrinsics:

`_mm_i64gather_pd()`:

```
result[63:0] = mem[base+vindex[63:0]*scale];
result[127:64] = mem[base+vindex[127:64]*scale];
```

`_mm256_i64gather_pd()`:

```
result[63:0] = mem[base+vindex[63:0]*scale];
result[127:64] = mem[base+vindex[127:64]*scale];
result[191:128] = mem[base+vindex[191:128]*scale];
result[255:192] = mem[base+vindex[255:192]*scale];
```

Returns

A 128/256-bit vector with unconditionally gathered double-precision FP values.

_mm_mask_i32gather_ps, _mm256_mask_i32gather_ps

Gathers 2/4 packed single-precision floating point values from memory referenced by the given base address, dword indices and scale, and using the given single-precision FP mask values. The corresponding Intel® AVX2 instruction is `VGATHERDPS`.

Syntax

```
extern __m128 _mm_mask_i32gather_ps(__m128 def_vals, float const * base, __m128i vindex
__m128 vmask, const int scale);
```

```
extern __m256 _mm256_mask_i32gather_ps(__m256 def_vals, float const * base, __m256i
vindex __m256 vmask, const int scale);
```

Arguments

def_vals	the vector of single-precision FP values copied to the destination when the corresponding element of the single-precision FP mask is '0'.
base	the base address used to reference the loaded FP elements.

vindex	the vector of dword indices used to reference the loaded FP elements.
vmask	the vector of FP elements used as a vector mask; only the most significant bit of each data element is used as a mask.
scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics conditionally load 2/4 packed single-precision floating-point values from memory using dword indices according to mask values.

Below is the pseudo-code for the intrinsics:

`_mm_mask_i32gather_ps():`

```
result[31:0] = (vmask[31]==1) ? (mem[base+vindex[31:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[63:32]*scale]) : (def_vals[63:32]);
result[95:64] = (vmask[95]==1) ? (mem[base+vindex[95:64]*scale]) : (def_vals[95:64]);
result127:96] = (vmask[127]==1) ? (mem[base+vindex[127:96]*scale]) : (def_vals[127:96]);
```

`_mm256_mask_i32gather_ps():`

```
result[31:0] = (vmask[31]==1) ? (mem[base+vindex[31:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[63:32]*scale]) : (def_vals[63:32]);
result[95:64] = (vmask[95]==1) ? (mem[base+vindex[95:64]*scale]) : (def_vals[95:64]);
result127:96] = (vmask[127]==1) ? (mem[base+vindex[127:96]*scale]) : (def_vals[127:96]);
result[159:128] = (vmask[159]==1) ? (mem[base+vindex[159:128]*scale]) : (def_vals[159:128]);
result[191:160] = (vmask[191]==1) ? (mem[base+vindex[191:160]*scale]) : (def_vals[191:160]);
result[223:192] = (vmask[223]==1) ? (mem[base+vindex[223:192]*scale]) : (def_vals[223:192]);
result[255:224] = (vmask[255]==1) ? (mem[base+vindex[255:224]*scale]) : (def_vals[255:224]);
```

Returns

A 128/256-bit vector with conditionally gathered single-precision FP values.

_mm_i32gather_ps, _mm256_i32gather_ps

Gathers 2/4 packed single-precision floating point values from memory referenced by the given base address, dword indices, and scale. The corresponding Intel© AVX2 instruction is `VGATHERDPS`.

Syntax

```
extern __m128 _mm_mask_i32gather_ps(float const * base, __m128i vindex, const int
scale);
```

```
extern __m256 _mm256_mask_i32gather_ps(float const * base, __m256i vindex, const int
scale);
```

Arguments

base	the base address used to reference the loaded FP elements.

vindex	the vector of dword indices used to reference the loaded FP elements.
scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics load 2/4 packed single-precision floating-point values from memory using dword indices.

Below is the pseudo-code for the intrinsics:

`_mm_i32gather_ps()`:

```
result[31:0] = mem[base+vindex[31:0]*scale];
result[63:32] = mem[base+vindex[63:32]*scale];
result[95:64] = mem[base+vindex[95:64]*scale];
result127:96] = mem[base+vindex[127:96]*scale];
```

`_mm256_i32gather_ps()`:

```
result[31:0] = mem[base+vindex[31:0]*scale];
result[63:32] = mem[base+vindex[63:32]*scale];
result[95:64] = mem[base+vindex[95:64]*scale];
result127:96] = mem[base+vindex[127:96]*scale];
result[159:128] = mem[base+vindex[159:128]*scale];
result[191:160] = mem[base+vindex[191:160]*scale];
result[223:192] = mem[base+vindex[223:192]*scale];
result[255:224] = mem[base+vindex[255:224]*scale];
```

Returns

A 128/256-bit vector with unconditionally gathered single-precision FP values.

_mm_mask_i64gather_ps, _mm256_mask_i64gather_ps

Gathers 2/4 packed single-precision floating point values from memory referenced by the given base address, qword indices and scale, and using the given single-precision FP mask values. The corresponding Intel® AVX2 instruction is `VGATHERQPS`.

Syntax

```
extern __m128 _mm_mask_i64gather_ps(__m128 def_vals, float const * base, __m128i vindex, __m128 vmask, const int scale);
```

```
extern __m128 _mm256_mask_i64gather_ps(float const * base, __m256i vindex, __m256i vmask, const int scale);
```

Arguments

def_vals	the vector of single-precision FP values copied to the destination when the corresponding element of the single-precision FP mask is '0'.
base	the base address used to reference the loaded FP elements.

vindex	the vector of qword indices used to reference the loaded FP elements.
vmask	the vector of FP elements used as a vector mask; only the most significant bit of each data element is used as a mask.
scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics conditionally load 2/4 packed single-precision floating-point values from memory using qword indices and updates the destination operand. The intrinsic `_mm_mask_i64gather_ps()` also sets the upper 64-bits of the result to '0'.

Below is the pseudo-code for the intrinsics:

`_mm_mask_i64gather_ps():`

```
result[31:0] = (vmask[31]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[63:32]);
result[127:64] = 0;
```

`_mm256_mask_i64gather_ps():`

```
result[31:0] = (vmask[31]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[63:32]);
result[95:64] = (vmask[95]==1) ? (mem[base+vindex[191:128]*scale]) : (def_vals[95:64]);
result[127:96] = (vmask[127]==1) ? (mem[base+vindex[255:192]*scale]) : (def_vals[127:96]);
```

Returns

A 256/128-bit vector with conditionally gathered single-precision FP values.

_mm_i64gather_ps, _mm256_i64gather_ps

Gathers 2/4 packed single-precision floating point values from memory referenced by the given base address, qword indices and scale. The corresponding Intel® AVX2 instruction is `VGATHERQPS`.

Syntax

```
extern __m128 _mm_mask_i64gather_ps(float const * base, __m128i vindex, const int
scale);
```

```
extern __m128 _mm256_mask_i64gather_ps(float const * base, __m256i vindex, const int
scale);
```

Arguments

base	the base address used to reference the loaded FP elements.
vindex	the vector of qword indices used to reference the loaded FP elements.

scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics load 2/4 packed single-precision floating-point values from memory using qword indices and updates the destination operand. The intrinsic `_mm_i64gather_ps()` also sets the upper 64-bits of the result to '0'.

Below is the pseudo-code for the intrinsics:

`_mm_i64gather_ps()`:

```
result[31:0] = mem[base+vindex[63:0]*scale];
result[63:32] = mem[base+vindex[127:64]*scale];
result[127:64] = 0;
```

`_mm256_i64gather_ps()`:

```
result[31:0] = mem[base+vindex[63:0]*scale];
result[63:32] = mem[base+vindex[127:64]*scale];
result[95:64] = mem[base+vindex[191:128]*scale];
result[127:96] = mem[base+vindex[255:192]*scale];
```

Returns

A 128/256-bit vector with unconditionally gathered single-precision FP values.

_mm_mask_i32gather_epi32, _mm256_mask_i32gather_epi32

Gathers 2/4 doubleword values from memory referenced by the given base address, dword indices, and scale, using the given dword mask values. The corresponding Intel® AVX2 instruction is `VPGATHERDD`.

Syntax

```
extern __m128i _mm_mask_i32gather_epi32(__m128i def_vals, int const * base, __m128i vindex, __m128i vmask, const int scale);
```

```
extern __m256i _mm256_mask_i32gather_epi32(__m256i def_vals, int const * base, __m256i vindex, __m256i vmask, const int scale);
```

Arguments

def_val	the vector of dword values copied to the destination when the corresponding element of the vector mask is '0'.
base	the base address used to reference the loaded dword elements.
vindex	the vector of dword indices used to reference the loaded dword elements.
vmask	the vector of dword elements used as a vector mask; only the most significant bit of each dword is used as a mask.

scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics conditionally loads 2/4 doubleword values from memory referenced by the given base address, dword indices and scale, and using the given dword mask values.

Below is the pseudo-code for the intrinsics:

`_mm_mask_i32gather_epi32()`:

```
result[31:0] = (vmask[31]==1) ? (mem[base+vindex[31:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[63:32]*scale]) : (def_vals[63:32]);
result[95:64] = (vmask[95]==1) ? (mem[base+vindex[95:64]*scale]) : (def_vals[95:64]);
result127:96] = (vmask[127]==1) ? (mem[base+vindex[127:96]*scale]) : (def_vals[127:96]);
```

`_mm256_mask_i32gather_epi32()`:

```
result[31:0] = (vmask[31]==1) ? (mem[base+vindex[31:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[63:32]*scale]) : (def_vals[63:32]);
result[95:64] = (vmask[95]==1) ? (mem[base+vindex[95:64]*scale]) : (def_vals[95:64]);
result127:96] = (vmask[127]==1) ? (mem[base+vindex[127:96]*scale]) : (def_vals[127:96]);
result[159:128] = (vmask[159]==1) ? (mem[base+vindex[159:128]*scale]) : (def_vals[159:128]);
result[191:160] = (vmask[191]==1) ? (mem[base+vindex[191:160]*scale]) : (def_vals[191:160]);
result[223:192] = (vmask[223]==1) ? (mem[base+vindex[223:192]*scale]) : (def_vals[223:192]);
result[255:224] = (vmask[255]==1) ? (mem[base+vindex[255:224]*scale]) : (def_vals[255:224]);
```

Returns

A 128/256 vector with conditionally gathered integer32 values.

_mm_i32gather_epi32, _mm256_i32gather_epi32

Gathers 2/4 doubleword values from memory referenced by the given base address, dword indices, and scale. The corresponding Intel® AVX2 instruction is `VPGATHERDD`.

Syntax

`extern __m128i _mm_i32gather_epi32(int const * base, __m128i vindex, const int scale);`

`extern __m256i _mm256_i32gather_epi32(int const * base, __m256i vindex, const int scale);`

Arguments

base	the base address used to reference the loaded dword elements.
vindex	the vector of dword indices used to reference the loaded dword elements.
scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics load 2/4 doubleword values from memory using the base address, qword indices, and 32-bit scale.

Below is the pseudo-code for the intrinsics:

`_mm_i32gather_epi32()`:

```
result[31:0] = mem[base+vindex[31:0]*scale];
result[63:32] = mem[base+vindex[63:32]*scale];
result[95:64] = mem[base+vindex[95:64]*scale];
result127:96] = mem[base+vindex[127:96]*scale];
```

`_mm256_i32gather_epi32()`:

```
result[31:0] = mem[base+vindex[31:0]*scale];
result[63:32] = mem[base+vindex[63:32]*scale];
result[95:64] = mem[base+vindex[95:64]*scale];
result127:96] = mem[base+vindex[127:96]*scale];
result[159:128] = mem[base+vindex[159:128]*scale];
result[191:160] = mem[base+vindex[191:160]*scale];
result[223:192] = mem[base+vindex[223:192]*scale];
result[255:224] = mem[base+vindex[255:224]*scale];
```

Returns

A 128/256-bit vector with unconditionally gathered integer32 values.

_mm_mask_i32gather_epi64,_mm256_mask_i32gather_epi64

Gathers 2/4 quadword values from memory referenced by the given base address, dword indices, and scale, and using the given qword mask values. The corresponding Intel® AVX2 instruction is `VPGATHERDQ`.

Syntax

```
extern __m128i _mm_mask_i32gather_epi64(__m128i def_vals, __int64 const * base, __m128i vindex, __m128i vmask, const int scale);
```

```
extern __m256i _mm256_mask_i32gather_epi64(__m256i def_vals, __int64 const * base, __m128i vindex, __m256i vmask, const int scale);
```

Arguments

def_val	the vector of qword values copied to the destination when the corresponding element of the vector mask is '0'.
base	the base address used to reference the loaded qword elements.
vindex	the vector of dword indices used to reference the loaded qword elements.
vmask	the vector of qword elements used as a vector mask; only the most significant bit of each qword is used as a mask.

scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics conditionally load 2/4 quadword values from memory referenced by the given base address, dword indices and scale, and using the given qword mask values.

Below is the pseudo-code for the intrinsics:

`_mm_mask_i32gather_epi64():`

```
result[63:0] = (vmask[63]==1) ? (mem[base+vindex[31:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem[base+vindex[63:32]*scale]) : (def_vals[127:64]);
```

`_mm256_mask_i32gather_epi64():`

```
result[63:0] = (vmask[63]==1) ? (mem[base+vindex[31:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem[base+vindex[63:32]*scale]) : (def_vals[127:64]);
result[191:128] = (vmask[191]==1) ? (mem[base+vindex[95:64]*scale]) : (def_vals[191:128]);
result[255:192] = (vmask[255]==1) ? (mem[base+vindex[127:96]*scale]) : (def_vals[255:192]);
```

Returns

A 256/128-bit vector with conditionally gathered interger64 values.

_mm_i32gather_epi64,_mm256_i32gather_epi64

Gathers 2/4 quadword values from memory referenced by the given base address, dword indices and scale. The corresponding Intel® AVX2 instruction is `VPGATHERDQ`.

Syntax

```
extern __m128i _mm_i32gather_epi64(__int64 const * base, __m128i vindex, const int scale);
```

```
extern __m256i _mm256_i32gather_epi64(__int64 const * base, __m128i vindex, const int scale);
```

Arguments

base	the base address used to reference the loaded qword elements.
vindex	the vector of dword indices used to reference the loaded qword elements.
scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics load 2/4 quadword values from memory using the base address, dword indices, and 64-bit scale.

Below is the pseudo-code for the intrinsics:

`_mm_i32gather_epi64()`:

```
result[63:0] = mem[base+vindex[31:0]*scale];
result[127:64] = mem[base+vindex[63:32]*scale];
```

`_mm256_i32gather_epi64()`:

```
result[63:0] = mem[base+vindex[31:0]*scale];
result[127:64] = mem[base+vindex[63:32]*scale];
result[191:128] = mem[base+vindex[95:64]*scale];
result[255:192] = mem[base+vindex[127:96]*scale];
```

Returns

A 128/256-bit vector with unconditionally gathered integer64 values.

_mm_mask_i64gather_epi32,_mm256_mask_i64gather_epi32

Gathers 2/4 doubleword values from memory referenced by the given base address, qword indices and scale, and using the given dword mask values. The corresponding Intel© AVX2 instruction is `VPGATHERQD`.

Syntax

```
extern __m128i _mm_mask_i64gather_epi32(__m128i def_vals, int const * base, __m128i vindex, __m128i vmask, const int scale);
```

```
extern __m256i _mm256_mask_i64gather_epi32(__m128i def_vals, int const * base, __m256i vindex, __m128i vmask, const int scale);
```

Arguments

def_val	the vector of dword values copied to the destination when the corresponding element of the vector mask is '0'.
base	the base address used to reference the loaded dword elements.
vindex	the vector of qword indices used to reference the loaded dword elements.
vmask	the vector of dword elements used as a vector mask; only the most significant bit of each dword is used as a mask.
scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics conditionally load 2/4 doubleword values from memory using the base address, qword indices and 32-bit scale. The intrinsic `_mm_mask_i64gather_epi32()` also sets the upper 64-bits of the result to '0'.

Below is the pseudo-code for the intrinsics:

_mm_mask_i64gather_epi32():

```
result[31:0] = (vmask[31]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[63:32]);
result[127:64] = 0;
```

_mm256_mask_i64gather_epi32():

```
result[31:0] = (vmask[31]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[31:0]);
result[63:32] = (vmask[63]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[63:32]);
result[95:64] = (vmask[95]==1) ? (mem[base+vindex[191:128]*scale]) : (def_vals[95:64]);
result[127:96] = (vmask[127]==1) ? (mem[base+vindex[255:192]*scale]) : (def_vals[127:96]);
```

Returns

A 128/256-bit vector with conditionally gathered integer32 values.

_mm_i64gather_epi32,_mm256_i64gather_epi32

Gathers 2/4 doubleword values from memory referenced by the given base address, qword indices, and scale. The corresponding Intel® AVX2 instruction is `VPGATHERQD`.

Syntax

`extern __m128i _mm_i64gather_epi32(int const * base, __m128i vindex, const int scale);`

`extern __m128i _mm256_i64gather_epi32(int const * base, __m256i vindex, const int scale);`

Arguments

base	the base address used to reference the loaded dword elements.
vindex	the vector of qword indices used to reference the loaded dword elements.
scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics load 2/4 doubleword values from memory using the base address, qword indices, and 32-bit scale. The intrinsic `_mm_i64gather_epi32()` also sets the upper 64-bits of the result to '0'.

Below is the pseudo-code for the intrinsics:

_mm_i64gather_epi32():

```
result[31:0] = mem[base+vindex[63:0]*scale];
result[63:32] = mem[base+vindex[127:64]*scale];
result[127:64] = 0;
```

_mm256_i64gather_epi32():

```
result[31:0] = mem[base+vindex[63:0]*scale];
result[63:32] = mem[base+vindex[127:64]*scale];
result[95:64] = mem[base+vindex[191:128]*scale];
result[127:96] = mem[base+vindex[255:192]*scale];
```

Returns

A 128/256-bit vector with unconditionally gathered integer32 values.

_mm_mask_i64gather_epi64,_mm256_mask_i64gather_epi64

Gathers 2/4 quadword values from memory referenced by the given base address, qword indices and scale, and using the given qword mask values. The corresponding Intel® AVX2 instruction is `VPGATHERQQ`.

Syntax

```
extern __m128i _mm_mask_i64gather_epi64(__m128i def_vals, __int64 const * base, __m128i
vindex, __m128i vmask, const int scale);
```

```
extern __m256i _mm256_mask_i64gather_epi64(__m128i def_vals, __int64 const * base,
__m256i vindex, __m256i vmask, const int scale);
```

Arguments

def_val	the vector of qword values copied to the destination when the corresponding element of the vector mask is '0'.
base	the base address used to reference the loaded qword elements.
vindex	the vector of qword indices used to reference the loaded qword elements.
vmask	the vector of qword elements used as a vector mask; only the most significant bit of each qword is used as a mask.
scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics conditionally load 2/4 quadword values from memory using the base address, qword indices and 64-bit scale.

Below is the pseudo-code for the intrinsics:

`_mm_mask_i64gather_epi64()`:

```
result[63:0] = (vmask[63]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[127:64]);
```

`_mm256_mask_i64gather_epi64()`:

```
result[63:0] = (vmask[63]==1) ? (mem[base+vindex[63:0]*scale]) : (def_vals[63:0]);
result[127:64] = (vmask[127]==1) ? (mem[base+vindex[127:64]*scale]) : (def_vals[127:64]);
result[191:128] = (vmask[191]==1) ? (mem[base+vindex[191:128]*scale]) : (def_vals[191:128]);
result[255:192] = (vmask[255]==1) ? (mem[base+vindex[255:192]*scale]) : (def_vals[255:192]);
```

Returns

A 128/256-bit vector with conditionally gathered integer64 values.

_mm_i64gather_epi64,_mm256_i64gather_epi64

Gathers 2/4 quadword values from memory referenced by the given base address, qword indices, and scale. The corresponding Intel® AVX2 instruction is `VPGATHERQQ`.

Syntax

```
extern __m128i _mm_i64gather_epi64(__int64 const * base, __m128i vindex, const int scale);
```

```
extern __m256i _mm256_i64gather_epi64(__int64 const * base, __m256i vindex, const int scale);
```

Arguments

base	the base address used to reference the loaded qword elements.
vindex	the vector of qword indices used to reference the loaded qword elements.
scale	The compilation time literal constant, which is used as the vector indices scale to address the loaded elements. Possible values are one of the following: 1, 2, 4, 8.

Description

The intrinsics load 2/4 quadword values from memory using the base address, qword indices, and 64-bit scale.

Below is the pseudo-code for the intrinsics:

`_mm_i64gather_epi64()`:

```
result[63:0] = mem[base+vindex[63:0]*scale];
result[127:64] = mem[base+vindex[127:64]*scale];
```

`_mm256_i64gather_epi64()`:

```
result[63:0] = mem[base+vindex[63:0]*scale];
result[127:64] = mem[base+vindex[127:64]*scale];
result[191:128] = mem[base+vindex[191:128]*scale];
result[255:192] = mem[base+vindex[255:192]*scale];
```

Returns

A 128/256-bit vector with unconditionally gathered integer64 values.

Intrinsics for Logical Shift Operations

_mm256_sll_epi16/32/64

Logical shift of word/doubleword/quadword elements to left according to specified number. The corresponding Intel® AVX2 instruction is `VPSLLW`, `VPSLLD`, or `VPSLLQ`.

Syntax

```
extern __m256i _mm256_sll_epi16(__m256i s1, __m128i count);
extern __m256i _mm256_sll_epi32(__m256i s1, __m128i count);
extern __m256i _mm256_sll_epi64(__m256i s1, __m128i count);
```

Arguments

s1	integer source vector used for the operation
count	128-bit memory location used for the operation

Description

Performs logical shift of bits in the individual data elements (16-bit word, 32-bit doubleword, or 64-bit quadword) in source vector *s1* to the left by the number of bits specified in *count*. The empty low-order bytes are cleared (set to all '0'). If the value specified by *count* is greater than 15/31/63 (depending on the intrinsic being used), the destination vector is set to all '0'.

The *count* argument is a 128-bit memory location. Note that only the first 64-bits of a 128-bit count operand are checked to compute the count.

Returns

Result of the left-shift operation.

_mm256_slli_epi16/32/64

Logical shift of word/doubleword/quadword elements to left according to specified number. The corresponding Intel© AVX2 instruction is `VPSLLW`, `VPSLLD`, or `VPSLLQ`.

Syntax

```
extern __m256i _mm256_slli_epi16(__m256i s1, int count);
extern __m256i _mm256_slli_epi32(__m256i s1, int count);
extern __m256i _mm256_slli_epi64(__m256i s1, int count);
```

Arguments

s1	integer source vector used for the operation
count	8-bit immediate used for the operation

Description

Performs a logical shift of bits in the individual data elements (words, doublewords, or quadword) in source vector *s1* to the left by the number of bits specified in *count*. The empty low-order bytes are cleared (set to all '0'). If the value specified by *count* is greater than 15/31/63 (depending on the intrinsic being used), the destination vector is set to all 0s. The *count* argument is an 8-bit immediate.

Returns

Result of the left-shift operation.

_mm256_sllv_epi32/64

Logical shift of doubleword/quadword elements to left according variable values. The corresponding Intel® AVX2 instruction is `VPSLLVD` *or* `VPSLLVQ`*.*

Syntax

```
extern __m256i _mm256_sllv_epi32(__m256i s1, __m256i s2);
```

```
extern __m256i _mm256_sllv_epi64(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector providing variable values for shift operation

Description

Performs a logical shift of 32 or 64 bits (doublewords, or quadword) in the individual data elements in source vector *s1* to the left by the count value of corresponding data elements in source vector *s2*. As the bits in the data elements are shifted left, the empty low-order bits are cleared (set to '0').

The count values are specified individually in each data element of the second source vector. If the unsigned integer value specified in the respective data element of the second source vector is greater than 31 (for a doubleword), or 63 (for a quadword), then the destination data elements are set to '0'.

Returns

Result of the left-shift operation.

_mm_sllv_epi32/64

Logical shift of word/doubleword elements in a 128-bit vector to left according variable values. The corresponding Intel® AVX2 instruction is `VPSLLVD` *or* `VPSLLVQ`*.*

Syntax

```
extern __m128i _mm_sllv_epi32(__m128i s1, __m128i s2);
```

```
extern __m128i _mm_sllv_epi64(__m128i s1, __m128i s2);
```

Arguments

s1	128-bit integer source vector used for the operation
s2	128-bit integer source vector providing variable values for shift operation

Description

Performs a logical shift of 32 or 64 bits (doublewords, or quadword) in the individual data elements in source vector *s1* to the left by the count value of corresponding data elements in source vector *s2*. As the bits in the data elements are shifted left, the empty low-order bits are cleared (set to '0').

The count values are specified individually in each data element of the second source vector. If the unsigned integer value specified in the respective data element of the second source vector is greater than 31 (for a doubleword), or 63 (for a quadword), then the destination data elements are set to '0'.

Returns

Result of the left-shift operation.

_mm256_slli_si256

Logical shift of byte elements to left according to specified number. The corresponding Intel® AVX2 instruction is `VPSLLDQ`.

Syntax

```
extern __m256i _mm256_slli_si256(__m256i s1, const int count);
```

Arguments

s1	integer source vector used for the operation
count	8-bit immediate used for the operation

Description

Performs a logical shift of 8-bit [byte] elements within a 128-bit lane of the source vector *s1* to the left by the number of bytes specified in *count*. The empty low-order bytes are cleared (set to all '0'). If the value specified by *count* is greater than 15, the destination vector is set to all 0s. The *count* argument is an 8-bit immediate.

Returns

Result of the left-shift operation.

_mm256_srli_si256

Logical shift of byte elements to right according to specified number. The corresponding Intel® AVX2 instruction is `VPSRLDQ`.

Syntax

```
extern __m256i _mm256_srli_si256(__m256i s1, const int count);
```

Arguments

s1	integer source vector used for the operation
count	8-bit immediate used for the operation

Description

Performs a logical shift of 8-bit [byte] elements within a 128-bit lane of source vector *s1* to the right by the number of bytes specified in *count*. The empty low-order bytes are cleared (set to all '0'). If the value specified by *count* is greater than 15, the destination vector is set to all '0'. The *count* argument is an 8-bit immediate.

Returns

Result of the right-shift operation.

_mm256_srl_epi16/32/64

Logical shift of word/doubleword/quadword elements to right according to specified number. The corresponding Intel® AVX2 instruction is `VPSRLW`*,* `VPSRLD`*, or* `VPSRLQ`*.*

Syntax

```
extern __m256i _mm256_srl_epi16(__m256i s1, __m128i count);
```

```
extern __m256i _mm256_srl_epi32(__m256i s1, __m128i count);
```

```
extern __m256i _mm256_srl_epi64(__m256i s1, __m128i count);
```

Arguments

s1	integer source vector used for the operation
count	128-bit memory location used for the operation

Description

Performs a logical shift of the bits in the individual data elements (16-bit word, 32-bit doubleword, or 64-bit quadword) in source vector *s1* to the right by the number of bits specified in *count*. The empty low-order bytes are cleared (set to all '0'). If the value specified by *count* is greater than 15/31/63 (depending on the intrinsic being used), the destination vector is set to all '0'.

The *count* argument is a 128-bit memory location. Note that only the first 64-bits of a 128-bit count operand are checked to compute the count.

Returns

Result of the right-shift operation.

_mm256_srli_epi16/32/64

Logical shift of word/doubleword/quadword elements to right according to specified number. The corresponding Intel® AVX2 instruction is `VPSRLW`*,* `VPSRLD`*, or* `VPSRLQ`*.*

Syntax

```
extern __m256i _mm256_srli_epi16(__m256i s1, int count);
```

```
extern __m256i _mm256_srli_epi32(__m256i s1, int count);
```

```
extern __m256i _mm256_srli_epi64(__m256i s1, int count);
```

Arguments

s1	integer source vector used for the operation
count	8-bit immediate used for the operation

Description

Performs a logical shift of bits in the individual data elements (16-bit word, 32-bit doubleword, or 64-bit quadword) in source vector *s1* to the right by the number of bits specified in *count*. The empty low-order bytes are cleared (set to all '0'). If the value specified by *count* is greater than 15/31/63 (depending on the intrinsic being used), the destination vector is set to all '0'. The *count* argument is an 8-bit immediate.

Returns

Result of the right-shift operation.

_mm256_srlv_epi32/64

Logical shift of doubleword/quadword elements to right according variable values. The corresponding Intel© AVX2 instruction is `VPSRLVD` or `VPSRLVQ`.

Syntax

```
extern __m256i _mm256_srlv_epi32(__m256i s1, __m256i s2);
```

```
extern __m256i _mm256_srlv_epi64(__m256i s1, __m256i s2);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector providing variable values for shift operation

Description

Performs a logical shift of 32 or 64 bits (doublewords, or quadword) in the individual data elements in source vector *s1* to the right by the count value of corresponding data elements in source vector *s2*. As the bits in the data elements are shifted right, the empty low-order bits are cleared (set to '0').

The count values are specified individually in each data element of the second source vector. If the unsigned integer value specified in the respective data element of the second source vector is greater than 31 (for a doubleword), or 63 (for a quadword), then the destination data elements are set to '0'.

Returns

Result of the right-shift operation.

_mm_srlv_epi32/64

Logical shift of word/doubleword elements in a 128-bit vector to right according variable values. The corresponding Intel© AVX2 instruction is `VPSRLVD` or `VPSRLVQ`.

Syntax

```
extern __m128i _mm_srlv_epi32(__m128i s1, __m128i s2);
```

```
extern __m128i _mm_srlv_epi64(__m128i s1, __m128i s2);
```

Arguments

s1	128-bit integer source vector used for the operation
s2	128-bit integer source vector providing variable values for shift operation

Description

Performs a logical shift of 32 or 64 bits (doublewords, or quadword) in the individual data elements in source vector *s1* to the right by the count value of corresponding data elements in the source vector *s2*. As the bits in the data elements are shifted right, the empty low-order bits are cleared (set to '0').

The count values are specified individually in each data element of the second source vector. If the unsigned integer value specified in the respective data element of the second source vector is greater than 31 (for a doubleword), or 63 (for a quadword), then the destination data element are set to '0'.

Returns

Result of the right-shift operation.

Intrinsics for Insert/Extract Operations

_mm256_inserti128_si256

Inserts 128-bits of packed integer data of the second source vector into the destination vector at a 128-bit offset from imm8[0]. The corresponding Intel® AVX2 instruction is `VINSERTI128`*.*

Syntax

```
extern __m256i _mm256_inserti128_si256(__m256i a, __m128i b, const int mask);
```

Arguments

a	integer source vector
b	integer source vector
mask	integer constant specifying offset

Description

Inserts 128-bits of packed integer data from the second source operand (third operand) into the destination operand (first operand) at a 128-bit offset from `imm8[0]`. The remaining portions of the destination are written by the corresponding fields of the first source operand (second operand). The high 7 bits of the immediate are ignored.

Returns

_mm256_extracti128_si256

Extracts 128-bits of packed integer data of the second source vector into the destination vector at a 128-bit offset from imm8[0]. The corresponding Intel® AVX2 instruction is `VEXTRACTI128`*.*

Syntax

```
extern __m128i _mm256_extracti128_si256(__m256i a, int offset);
```

Arguments

a	integer source vector
offset	integer constant specifying offset

Description

Extract 128 bits (composed of integer data) from a, selected with imm, and store the result in dst.

Extracts 128-bits of packed integer data from source vector *a* with *offset*. The remaining portions of the destination are written by the corresponding fields of the source vector. The destination may be either an *XMM* register or a 128-bit memory location. The high 7 bits of the immediate are ignored.

Returns

_mm256_insert_epi8/16/32/64

Insert 8/16/32/64-bit integer into a vector of integers at the position specified by index.

Syntax

```
extern __m256i _mm256_insert_epi8(__m256i a, int8 i, const int index);
extern __m256i _mm256_insert_epi16(__m256i a, int16 i, const int index);
extern __m256i _mm256_insert_epi32(__m256i a, int32 i, const int index);
extern __m256i _mm256_insert_epi64(__m256i a, int64 i, const int index);
```

Arguments

a	integer source vector
i	integer value to insert
offset	integer constant specifying offset

Description

Insert an integer value, *i* into the corresponding position of an integer source vector, *a*, and return the resulting vector.

_mm256_extract_epi8/16/32/64

Extract integer byte or word from packed integer array element selected by index.

Syntax

```
extern int _mm256_extract_epi8(__m256i a, int offset);
extern int _mm256_extract_epi16(__m256i a, int offset);
extern int _mm256_extract_epi32(__m256i a, int offset);
extern int _mm256_extract_epi64(__m256i a, int offset);
```

Arguments

a	integer source vector
offset	integer constant specifying offset

Description

Returns extracted 8/16/32/64 bits of data of the source vector at offset position. Offset counts with element size granularity.

Upper bits of returned integer value are cleared.

Intrinsics for Masked Load/Store Operations

_mm_maskload_epi32/64, _mm256_maskload_epi32/64

Conditionally loads dwords/qwords from the specified memory location, depending on the mask bits associated with each data element. The corresponding Intel® AVX2 instruction is `VPMASKMOVD` *or* `VPMASKMOVQ`.

Syntax

```
extern __m128i _mm_maskload_epi32(int const * addr, __m128i mask);
extern __m256i _mm256_maskload_epi32(int const * addr, __m256i mask);
extern __m128i _mm_maskload_epi64(__int64 const * addr, __m128i mask);
extern __m256i _mm256_maskload_epi64(__int64 const * addr, __m256i mask);
```

Arguments

addr	pointer to data to be loaded
mask	integer source vector

Description

Conditionally loads 32/64-bit data elements from the memory referenced by the `addr` and stores it into the corresponding data element of the result vector. If an element of mask is 0, the 32/64-bit zero is written to the corresponding element of the result vector. The mask bit for each data element is the most significant bit of that element in mask.

Returns

Result of the masked load operation.

_mm_maskstore_epi32/64, _mm256_maskstore_epi32/64

Conditionally stores dwords/qwords from the source vector to the specified memory location, depending on the given mask bits associated with each data element. The corresponding Intel® AVX2 instruction is `VPMASKMOVD` *or* `VPMASKMOVQ`.

Syntax

```
extern void _mm_maskstore_epi32(int * addr, __m128i vmask, __m128i val);
extern void _mm256_maskstore_epi32(int * addr, __m256i vmask, __m256i val);
extern void _mm_maskstore_epi64(__int64 * addr, __m128i vmask, __m128i val);
extern void _mm256_maskstore_epi64(__int64 * addr, __m256i vmask, __m256i val);
```

Arguments

addr	pointer to data to be loaded
vmask	vector mask. If element of vmask is 0, then the value in the memory is unchanged

val	location from where the elements are written to vector located in memory and referenced by "*addr*"

Description

Conditionally stores 32/64-bit data elements from the source vector into the corresponding elements of the vector in memory referenced by `addr`. If an element of mask is 0, corresponding element of the result vector in memory stays unchanged. Only the most significant bit of each element in the vector mask is used.

Returns

Result of the masked store operation.

Intrinsics for Miscellaneous Operations

_mm256_alignr_epi8

Aligns elements of two source vectors depending on bits in a mask. The corresponding Intel® AVX2 instruction is `VPALIGNR`*.*

Syntax

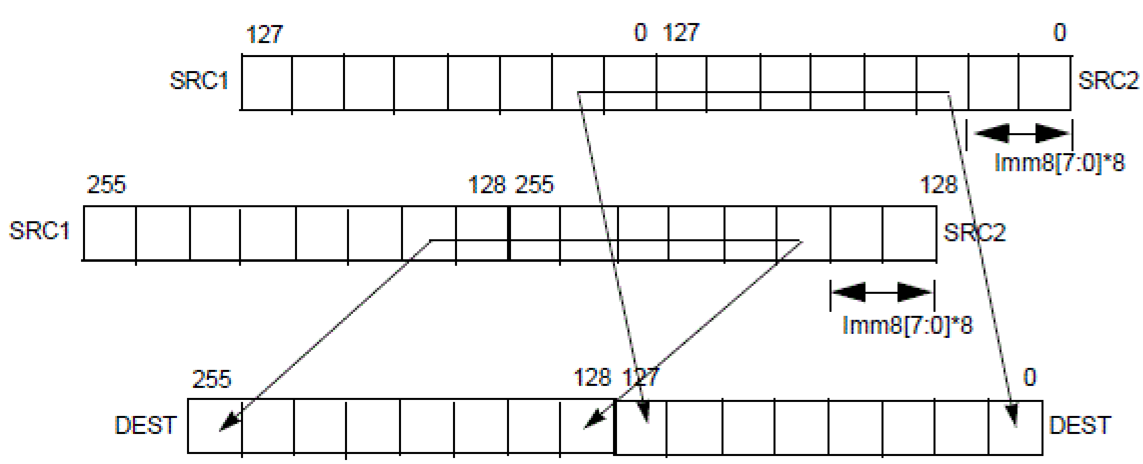
```
extern __m256i _mm256_alignr_epi8(__m256i s1, __m256i s2, const int mask);
```

Arguments

s1	integer source vector used for the operation
s2	integer source vector used for the operation
mask	8-bit immediate bits used for the operation

Description

Performs an alignment operation by concatenating two blocks of 16-byte data from the first and second source vectors, *s1* and *s2*, into an intermediate 32-byte composite, shifting the composite at byte granularity to the right by a constant immediate specified by mask, and extracting the right-aligned 16-byte result into the destination vector. The immediate value is considered unsigned.



Returns

Result of the alignment operation.

_mm256_movemask_epi8

Moves byte mask from source vector. The corresponding Intel® AVX2 instruction is `VPMOVMSKB`*.*

Syntax

```
extern int _mm256_movemask_epi8(__m256i s1);
```

Arguments

s1	integer source vector used for the operation.

Description

Creates a mask from the most significant bit of each byte of source vector *s1* and stores the result in the in the returned doubleword value/mask.

Returns

Result of the move mask operation.

_mm256_stream_load_si256

Loads 256-bit data from memory using non-temporal aligned hint. The corresponding Intel® AVX2 instruction is `VMOVNTDQA`*.*

Syntax

```
extern __m256i _mm256_stream_load_si256(__m256i const *);
```

Arguments

s1	integer source vector used for the operation.

Description

Loads 256-bit data from the source operand to the destination operand using a non-temporal hint if the memory source is write combining memory type.

Intrinsics for Operations to Manipulate Integer Data at Bit-Granularity

_bextr_u32/64

Extracts contiguous bits from the first source operand to the destination using an index value and length value specified in the second source operand. The corresponding Intel® AVX2 instruction is `BEXTR`*.*

Syntax

```
extern unsigned int _bextr_u32(unsigned int source, unsigned int sb, unsigned int bl);
```

```
extern unsigned __int64 _bextr_u64(unsigned __int64 s1, unsigned int sb, unsigned int
bl);
```

Arguments

source	the source from where the bits are extracted
sb	start bit, the number of the bit from where the contiguous bits are extracted
bl	bit length, the number of bits to be extracted

Description

Extracts contiguous bits from the first source operand to the destination using an index value and length value specified in the second source operand. The extracted bits are written to the destination starting from the least significant bit. All higher order bits in the destination starting at bit position *bl* are zeroed. The destination is cleared if no bits are extracted.

Returns

Result of the operation.

_blsi_u32/64

Extracts the lowest set bit from the source operand and set the corresponding bit in the destination. The corresponding Intel® AVX2 instruction is `BLSI`*.*

Syntax

```
extern unsigned int _blsi_u32(unsigned int source);
```

```
extern unsigned __int64 _blsi_u64(unsigned __int64 source);
```

Arguments

source	the source from where the bits are extracted

Description

Extracts the lowest set bit from the source operand and sets the corresponding bit in the destination. All other bits in the destination are set to 0. If no bits are set in the source operand, all the bits in the destination are set to 0.

Returns

Result of the operation.

_blsmsk_u32/64

Sets all the lower bits of the destination to "1" up to and including lowest set bit (=1) in the source operand. The corresponding Intel® AVX2 instruction is `BLSMSK`*.*

Syntax

```
extern unsigned int _blsmsk_u32(unsigned int s1);
```

```
extern unsigned __int64 _blsmsk_u64(unsigned __int64 s1);
```

Arguments

s1	the source operand used for the operation

Description

Sets all the lower bits of the destination to "1" up to and including lowest set bit (=1) in the source operand. If source operand is 0, all bits of the destination are set to 1.

Returns

Result of the operation

_blsr_u32/64

Copies all bits from the source operand to the destination and resets (=0) the bit position in the destination that corresponds to the lowest set bit of the source operand. The corresponding Intel® AVX2 instruction is `BLSR`*.*

Syntax

```
extern unsigned int _blsr_u32(unsigned int s1);
```

```
extern unsigned __int64 _blsr_u64(unsigned __int64 s1);
```

Arguments

s1	the source operand from where the bits are copied

Description

Copies all bits from the source operand to the destination and resets (=0) the bit position in the destination that corresponds to the lowest set bit of the source operand.

Returns

Result of the operation

_bzhi_u32/64

Copies the bits of the first source operand into the destination and clears the higher bits in the destination according to the index value specified by the second source operand. The corresponding Intel® AVX2 instruction is `BZHI`*.*

Syntax

```
extern unsigned int _bzhi_u32(unsigned int source, unsigned int index);
```

```
extern unsigned __int64 _bzhi_u64(unsigned __int64 source, unsigned int index);
```

Arguments

source	the source operand from where the bits are copied
index	index value according to which the bits are copied

Description

Copies the bits of the first source operand into the destination and clears the higher bits in the destination according to the index value. The index value is specified by bits `7:0` of the second source operand.

Returns

Result of the operation.

_pext_u32/64

Transfer either contiguous or non-contiguous bits in the first source operand to contiguous low order bit positions in the destination according to the mask values. The corresponding Intel® AVX2 instruction is `PEXT`.

Syntax

```
extern unsigned int _pext_u32(unsigned int source, unsigned int mask);
```

```
extern unsigned __int64 _pext_u64(unsigned __int64 s1, unsigned __int64 mask);
```

Arguments

source	the source operand from where the bits are transferred
mask	mask value according to which the bits are transferred

Description

The intrinsics use a mask in the second source operand to transfer either contiguous or non-contiguous bits in the first source operand to contiguous, low-order bit positions in the destination. For each bit set in the mask, the intrinsic extracts the corresponding bits from the first source operand and writes them into contiguous lower bits of the destination. The remaining upper bits of the destination are set to 0.

Returns

Result of the operation

_pdep_u32/64

Transfer/scatter contiguous low order bits in the first source operand into the destination according to the mask in the second source operand. The corresponding Intel® AVX2 instruction is `PDEP`.

Syntax

```
extern unsigned int _pdep_u32(unsigned int source, unsigned int mask);
```

```
extern unsigned __int64 _pdep_u64(unsigned __int64 source, unsigned __int64 mask);
```

Arguments

source	the source operand from where the bits are transferred

mask	the mask value according to which the bits are transferred

Description

The intrinsics use a mask in the second source operand to transfer/scatter contiguous, low-order bits in the first source operand into the destination. It takes the low bits from the first source operand and deposit them in the destination at the corresponding bit locations that are set in the mask. All other bits (bits not set in mask) in the destination are set to 0.

Returns

Result of the operation

_lzcnt_u32/64

Counts the number of leading zero bits in a source operand. Returns operand size as output when source operand is zero. The corresponding Intel® AVX2 instruction is `LZCNT`*.*

Syntax

```
extern unsigned int _lzcnt_u32(unsigned int source);
```

```
extern unsigned __int64 _lzcnt_u64(unsigned __int64 source);
```

Arguments

source	the source operand used for the operation

Description

Counts the number of leading most significant zero bits in a source operand returning the result into a destination when source operand is 0.

Returns

Result of the operation.

_tzcnt_u32/64

Counts the number of trailing least significant zero bits in source operand and returns the result in destination. When source operand is 0, it returns its size in bits. The corresponding Intel® AVX2 instruction is `TZCNT`*.*

Syntax

```
extern unsigned int _tzcnt_u32(unsigned int source);
```

```
extern unsigned __int64 _tzcnt_u64(unsigned __int64 source);
```

Arguments

source	the source operand used for the operation

Description

Searches the source operand for the least significant set bit. If a least significant 1 bit is found, its bit index is returned, otherwise the result is the number of bits in the operand size.

Returns

Result of the operation.

Intrinsics for Pack/Unpack Operations

_mm256_packs_epi16/32

Pack signed word/doubleword integers to signed byte/ words integers and saturates. The corresponding Intel© AVX2 instruction is `VPACKSSWB` *or* `VPACKSSDW`*.*

Syntax

```
extern __m256i _mm256_packs_epi16(__m256i a, __m256i b);
extern __m256i _mm256_packs_epi32(__m256i a, __m256i b);
```

Arguments

a	integer source vector used for the operation
b	integer source vector used for the operation

Description

The `_mm256_packs_epi16` intrinsic converts 16 packed signed word integers from the first and the second source operands into 32 packed signed byte integers. The `_mm256_packs_epi32` intrinsic converts eight packed signed doubleword integers from the first and the second source operands into 16 packed signed word integers.

Returns

Result of the pack operation.

_mm256_packus_epi16/32

Pack signed word/doubleword integers to unsigned byte/word integers and saturates. The corresponding Intel© AVX2 instruction is `VPACKUSWB` *or* `VPACKUSDW`*.*

Syntax

```
extern __m256i _mm256_packus_epi16(__m256i a, __m256i b);
extern __m256i _mm256_packus_epi32(__m256i a, __m256i b);
```

Arguments

a	integer source operand used for the operation
b	integer source operand used for the operation

Description

The `_mm256_packus_epi16` intrinsic converts 16 packed signed word integers from source operands *a* and *b* into 32 packed unsigned byte integers. The `_mm256_packus_epi32` intrinsic converts eight packed signed doubleword integers from the source operands *a* and *b* into 16 packed unsigned word integers.

Returns

Result of the pack operation.

_mm256_unpackhi_epi8/16/32/64

Unpacks and interleaves the high-order data elements of the source vector with the high-order data elements in the destination vector. The corresponding Intel® AVX2 instruction is `VPUNPCKHBW`*,* `VPUNPCKHWD`*,* `VPUNPCKHDQ`*, or* `VPUNPCKHQDQ`*.*

Syntax

```
extern __m256i _mm256_unpackhi_epi8(__m256i a, __m256i b);
extern __m256i _mm256_unpackhi_epi16(__m256i a, __m256i b);
extern __m256i _mm256_unpackhi_epi32(__m256i a, __m256i b);
extern __m256i _mm256_unpackhi_epi64(__m256i a, __m256i b);
```

Arguments

a	integer source operand used for the operation
b	integer source operand used for the operation

Description

Unpacks and interleaves the high-order signed or unsigned data elements (bytes, words, doublewords, and quadwords) of the source vector and the high-order signed or unsigned data elements (bytes, words, doublewords, and quadwords) in the destination vector. The low-order data elements are ignored.

Returns

Result of the interleave operation

_mm256_unpacklo_epi8/16/32/64

Unpacks and interleaves the low-order data elements of the source vector with the low-order data elements in the destination vector. The corresponding Intel® AVX2 instruction is `VPUNPCKLBW`*,* `VPUNPCKLWD`*,* `VPUNPCKLDQ`*, or* `VPUNPCKLQDQ`*.*

Syntax

```
extern __m256i _mm256_unpacklo_epi8(__m256i a, __m256i b);
extern __m256i _mm256_unpacklo_epi16(__m256i a, __m256i b);
extern __m256i _mm256_unpacklo_epi32(__m256i a, __m256i b);
extern __m256i _mm256_unpacklo_epi64(__m256i a, __m256i b);
```

Arguments

a	integer source vector used for the operation
b	integer source vector used for the operation

Description

Unpacks and interleaves the low-order signed or unsigned data elements (bytes, words, doublewords, and quadwords) of the source vector and the low-order signed or unsigned data elements (bytes, words, doublewords, and quadwords) in the destination operand. The high-order data elements are ignored.

Returns

Result of the interleave operation

Intrinsics for Packed Move with Extend Operations

_mm256_cvtepi8_epi16/32/64

Performs packed move with sign-extend on 8-bit signed integers to 16/32/64-bit integers. The corresponding Intel© AVX2 instruction is `VPMOVSXBW`*,*`VPMOVSXBD`*, or* `VPMOVSXBQ`*.*

Syntax

```
extern __m256i _mm256_cvtepi8_epi16(__m128i s1);
```

```
extern __m256i _mm256_cvtepi8_epi32(__m128i s1);
```

```
extern __m256i _mm256_cvtepi8_epi64(__m128i s1);
```

Arguments

s1	128-bit integer source vector used for the operation

Description

Performs a packed move with sign-extend operation to convert 8-bit [byte] integers in the low bytes of the source vector, *s1*, to 16-bit [word], 32-bit [doubleword], or 64-bit [quadword] integers, which are stored as packed signed word/doubleword/quadword integers in the destination vector.

Returns

Result of the sign-extend operation.

_mm256_cvtepi16_epi32/64

Performs packed move with sign-extend on 16-bit signed integers to 32/64-bit integers. The corresponding Intel© AVX2 instruction is `VPMOVSXWD` *or*`VPMOVSXWQ`*.*

Syntax

```
extern __m256i _mm256_cvtepi16_epi32(__m128i s1);
```

```
extern __m256i _mm256_cvtepi16_epi64(__m128i s1);
```

Arguments

s1	128-bit integer source vector used for the operation

Description

Performs a packed move with sign-extend operation to convert 16-bit [word] integers in the low bytes of the source vector, *s1*, to 32-bit [doubleword] or 64-bit [quadword] integers and stored as packed signed doubleword/quadword integers in the destination vector.

Returns

Result of the sign-extend operation.

_mm256_cvtepi32_epi64

Performs packed move with sign-extend on 32-bit signed integers to 64-bit integers. The corresponding Intel® AVX2 instruction is `VPMOVSXDQ`.

Syntax

```
extern __m256i _mm256_cvtepi32_epi64(__m128i s1);
```

Arguments

s1	128-bit integer source vector used for the operation

Description

Performs a packed move with sign-extend operation to convert 32-bit [doubleword] integers in the low bytes of the source vector, *s1*, to 64-bit [quadword] integers and stored as packed signed quadword integers in the destination vector.

Returns

Result of the sign-extend operation.

_mm256_cvtepu8_epi16/32/64

Performs packed move with zero-extend on 8-bit unsigned integers to 16/32/64-bit integers. The corresponding Intel® AVX2 instruction is `VPMOVZXBW`,`VPMOVZXBD`, *or* `VPMOVZXBQ`.

Syntax

```
extern __m256i _mm256_cvtepu8_epi16(__m128i s1);
extern __m256i _mm256_cvtepu8_epi32(__m128i s1);
extern __m256i _mm256_cvtepu8_epi64(__m128i s1);
```

Arguments

s1	128-bit integer source vector used for the operation

Description

Performs a packed move with zero-extend operation to convert 8-bit [byte] integers in the low bytes of the source vector, *s1*, to 16-bit [word], 32-bit [doubleword], or 64-bit [quadword] integers and stored as packed unsigned word/doubleword/quadword integers in the destination vector.

Returns

Result of the zero-extend operation.

_mm256_cvtepu16_epi32/64

Performs packed move with zero-extend on 16-bit unsigned integers to 32/64-bit integers. The corresponding Intel® AVX2 instruction is `VPMOVZXWD` *or* `VPMOVZXWQ`*.*

Syntax

```
extern __m256i _mm256_cvtepu16_epi32(__m128i s1);
```

```
extern __m256i _mm256_cvtepu16_epi64(__m128i s1);
```

Arguments

s1	128-bit integer source vector used for the operation

Description

Performs a packed move with zero-extend operation to convert 16-bit [word] integers in the low bytes of the source vector, *s1*, to 32-bit [doubleword] or 64-bit [quadword] integers and stored as packed signed doubleword/quadword integers in the destination vector.

Returns

Result of the zero-extend operation.

_mm256_cvtepu32_epi64

Performs packed move with zero-extend on 32-bit unsigned integers to 64-bit integers. The corresponding Intel® AVX2 instruction is `VPMOVZXDQ`*.*

Syntax

```
extern __m256i _mm256_cvtepu32_epi64(__m128i s1);
```

Arguments

s1	128-bit integer source vector used for the operation

Description

Performs a packed move with zero-extend operation to convert 32-bit [doubleword] integers in the low bytes of the source vector, *s1*, to 64-bit [quadword] integers and stored as packed signed quadword integers in the destination vector.

Returns

Result of the zero-extend operation.

Intrinsics for Permute Operations

_mm256_permutevar8x32_epi32

Permutes doubleword elements of the source vector into the destination vector. The corresponding Intel® AVX2 instruction is `VPERMD`*.*

Syntax

```
extern __m256i _mm256_permutevar8x32_epi32(__m256i val, __m256i offsets);
```

Arguments

val	the vector of 32-bit integer elements to be permuted
offsets	the vector of eight 3-bit offsets (specifying values in range [0 - 7]) for the permuted elements of 256-bit vector

Description

Use the offset values in each dword element of the vector *offsets* to select a dword element from the source vector *val*. The result element is copied to the corresponding element of destination vector. The intrinsic does NOT allow to copy the same element of the source vector to more than one element of the destination vector.

Below is the pseudo-code for the intrinsic:

```
RESULT[31:0] <- (VAL[255:0] >> (OFFSETS[2:0] * 32))[31:0];
RESULT[63:32] <- (VAL[255:0] >> (OFFSETS[34:32] * 32))[31:0];
RESULT[95:64] <- (VAL[255:0] >> (OFFSETS[66:64] * 32))[31:0];
RESULT[127:96] <- (VAL[255:0] >> (OFFSETS[98:96] * 32))[31:0];
RESULT[159:128] <- (VAL[255:0] >> (OFFSETS[130:128] * 32))[31:0];
RESULT[191:160] <- (VAL[255:0] >> (OFFSETS[162:160] * 32))[31:0];
RESULT[223:192] <- (VAL[255:0] >> (OFFSETS[194:192] * 32))[31:0];
RESULT[255:224] <- (VAL[255:0] >> (OFFSETS[226:224] * 32))[31:0];
```

Returns

Result of the permute operation.

_mm256_permutevar8x32_ps

Permutes single-precision floating-point elements of the source vector into the destination vector. The corresponding Intel® AVX2 instruction is `VPERMPS`.

Syntax

```
extern __m256i _mm256_permutevar8x32_ps(__m256 val, __m256i offsets);
```

Arguments

val	the vector of 32-bit single-precision floating-point elements to be permuted
offsets	the vector of eight 3-bit offsets (specifying values in range [0 - 7]) for the permuted elements of 256-bit vector

Description

Use the offset values in each dword element of the vector *offsets* to select a single-precision floating-point element from the source vector *val*. The result element is copied to the corresponding element of destination vector. The intrinsic does NOT allow to copy the same element of the source vector to more than one element of the destination vector.

Below is the pseudo-code for the intrinsic:

```
RESULT[31:0] <- (VAL[255:0] >> (OFFSETS[2:0] * 32))[31:0];
RESULT[63:32] <- (VAL[255:0] >> (OFFSETS[34:32] * 32))[31:0];
RESULT[95:64] <- (VAL[255:0] >> (OFFSETS[66:64] * 32))[31:0];
RESULT[127:96] <- (VAL[255:0] >> (OFFSETS[98:96] * 32))[31:0];
RESULT[159:128] <- (VAL[255:0] >> (OFFSETS[130:128] * 32))[31:0];
RESULT[191:160] <- (VAL[255:0] >> (OFFSETS[162:160] * 32))[31:0];
RESULT[223:192] <- (VAL[255:0] >> (OFFSETS[194:192] * 32))[31:0];
RESULT[255:224] <- (VAL[255:0] >> (OFFSETS[226:224] * 32))[31:0];
```

Returns

Result of the permute operation.

_mm256_permute4x64_epi64

Permutes quadword integer values of the source vector into the destination vector. The corresponding Intel© AVX2 instruction is `VPERMQ`*.*

Syntax

```
extern __m256i _mm256_permute4x64_epi64(__m256i val, const int control);
```

Arguments

val	the vector of 64-bit quadword integer elements to be permuted
control	an integer specified as an 8-bit immediate

Description

Use two-bit index values in the immediate byte to select a qword integer element from the source vector *val*. The result element is copied to the corresponding element of destination vector. The intrinsic allows to copy the same element of the source vector to more than one element of the destination vector.

Below is the pseudo-code for the intrinsic:

```
RESULT[63:0] <- (VAL[255:0] >> (CONTROL[1:0] * 64))[63:0];
RESULT[127:64] <- (VAL[255:0] >> (CONTROL[3:2] * 64))[63:0];
RESULT[191:128] <- (VAL[255:0] >> (CONTROL[5:4] * 64))[63:0];
RESULT[255:192] <- (VAL[255:0] >> (CONTROL[7:6] * 64))[63:0];
```

Returns

Result of the permute operation.

_mm256_permute4x64_pd

Permutes quadword double-precision floating-point values of the source vector into the destination vector. The corresponding Intel© AVX2 instruction is `VPERMPD`*.*

Syntax

```
extern __m256i _mm256_permute4x64_epi64(__m256d val, const int control);
```

Arguments

val	the vector of 64-bit qword double-precision floating-point elements to be permuted
control	an integer specified as an 8-bit immediate

Description

Use two-bit index values in the immediate byte to select a qword double-precision floating-point element from the source vector *val*. The result element is copied to the corresponding element of destination vector. The intrinsic allows to copy the same element of the source vector to more than one element of the destination vector.

Below is the pseudo-code for the intrinsic:

```
RESULT[63:0] <- (VAL[255:0] >> (CONTROL[1:0] * 64))[63:0];
RESULT[127:64] <- (VAL[255:0] >> (CONTROL[3:2] * 64))[63:0];
RESULT[191:128] <- (VAL[255:0] >> (CONTROL[5:4] * 64))[63:0];
RESULT[255:192] <- (VAL[255:0] >> (CONTROL[7:6] * 64))[63:0];
```

Returns

Result of the permute operation.

_mm256_permute2x128_si256

Permutes 128-bit integer data from the first source vector and the second source vector in the destination vector. The corresponding Intel® AVX2 instruction is `VPERM2I128`*.*

Syntax

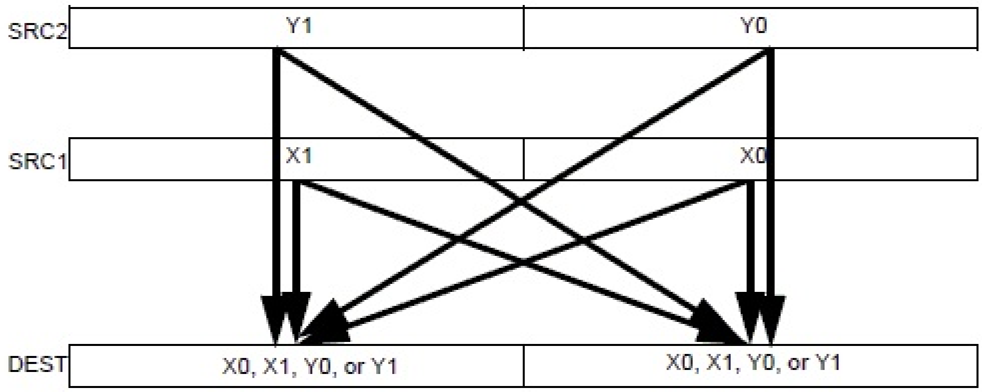
```
extern __m256i _mm256_permute2x128_si256(__m256i a, __m256i b, int control);
```

Arguments

a	integer source vector
b	integer source vector
control	8-bit immediate used for the operation

Description

Permutes 128-bit integer data from source vector `a` and source vector `b` using bits in the 8-bit immediate and stores results in the destination vector.



Returns

Result of the permute operation.

Intrinsics for Shuffle Operations

_mm256_shuffle_epi8

Shuffles bytes in the first source vector according to the shuffle control mask in the second source vector. The corresponding Intel© AVX2 instruction is `VPSHUFB`.

Syntax

`extern __m256i _mm256_shuffle_epi8(__m256i a, __m256i b);`

Arguments

a	integer source vector
b	integer source vector

Description

Performs shuffle operations of the signed or unsigned 8-bit integers in the source vector as specified by the shuffle control mask in the second source operand.

Below is the pseudocode interpreting `a`, `b`, and `r` as arrays of unsigned 8-bit integers:

```
for (i = 0; i < 16; i++){
  if (b[i] & 0x80){
    r[i] =  0;
  }
  else{
    r[i] = a[b[i] & 0x0F];
  }
  if (b[16+i] & 0x80){
    r[16+i] =  0;
  }
  else{
    r[16+i] = a[16+(b[16+i] & 0x0F)];
  }
}
```

Returns

Result of the shuffle operation.

_mm256_shuffle_epi32

Conditionally shuffles doublewords of the source vector in the destination vector at the locations selected with the immediate control operand. The corresponding Intel® AVX2 instruction is `VPSHUFD`.

Syntax

```
extern __m256i _mm256_shuffle_epi32(__m256i val, const int control);
```

Arguments

val	integer source vector
control	immediate control operand

Description

Performs shuffle operations of the signed or unsigned 32-bit integers in the source vector as specified by the control operand. The shuffle value must be an immediate.

Returns

Result of the shuffle operation.

_mm256_shufflehi_epi16

Shuffles the upper 4 high signed or unsigned words in each 128-bit lane of the source operand according to the shuffle control operand. The low qwords in each of 2 128-bit lanes of the source operand are copied to the corresponding low qwords of the result value. The corresponding Intel® AVX 2 instruction is `VPSHUFHW`.

Syntax

```
extern __m256i _mm256_shufflehi_epi16(__m256i val, const int control);
```

Arguments

val	integer source operand
control	immediate control mask

Description

Shuffles the upper four high signed or unsigned words in each 128-bit lane of the source operand according to the shuffle control operand. The low qwords in each of two 128-bit lanes of the source operand are copied to the corresponding low qwords of the result value. The shuffle control operand must be an immediate.

Below is the pseudo-code for the intrinsic:

```
RESULT[63:0] <- VAL[63:0]
RESULT[79:64] <- (VAL >> (CONTROL[1:0] *16))[79:64]
RESULT[95:80] <- (VAL >> (CONTROL[3:2] * 16))[79:64]
RESULT[111:96] <- (VAL >> (CONTROL[5:4] * 16))[79:64]
RESULT[127:112] <- (VAL >> (CONTROL[7:6] * 16))[79:64]
```

```
RESULT[191:128] <- VAL[191:128]
RESULT[207192] <- (VAL >> (CONTROL[1:0] *16))[207:192]
RESULT[223:208] <- (VAL >> (CONTROL[3:2] * 16))[207:192]
RESULT[239:224] <- (VAL >> (CONTROL[5:4] * 16))[207:192]

RESULT[255:240] <- (VAL >> (CONTROL[7:6] * 16))[207:192]
```

Returns

Result of the shuffle operation.

_mm256_shufflelo_epi16

Shuffles the low 4 signed or unsigned words in each 128-bit lane of the source operand according to the shuffle control operand. The high qwords in each of 2 128-bit lanes of the source operand are copied to the corresponding high qwords of the result value. The corresponding Intel© AVX 2 instruction is `VPSHUFLW`.

Syntax

```
extern __m256i _mm256_shufflelo_epi16(__m256i val, const int control);
```

Arguments

val	integer source vector
control	immediate control operand

Description

Shuffles the low four signed or unsigned words in each 128-bit lane of the source operand according to the shuffle control operand. The high qwords in each of 2 128-bit lanes of the source operand are copied to the corresponding high qwords of the result value. The shuffle value must be an immediate.

Below is the pseudo-code for the intrinsic:

```
RESULT[15:0] <- (VAL >> (CONTROL[1:0] *16))[15:0]
RESULT[31:16] <- (VAL >> (CONTROL[3:2] * 16))[15:0]
RESULT[47:32] <- (VAL >> (CONTROL[5:4] * 16))[15:0]
RESULT[63:48] <- (VAL >> (CONTROL[7:6] * 16))[15:0]
RESULT[127:64] <- VAL[127:64]
RESULT[143:128] <- (VAL >> (CONTROL[1:0] *16))[143:128]
RESULT[159:144] <- (VAL >> (CONTROL[3:2] * 16))[143:128]
RESULT[175:160] <- (VAL >> (CONTROL[5:4] * 16))[143:128]
RESULT[191:176] <- (VAL >> (CONTROL[7:6] * 16))[143:128]

RESULT[255:192] <- VAL[255:192]
```

Returns

Result of the shuffle operation.

Intrinsics for Intel® Transactional Synchronization Extensions (Intel® TSX)

Intel® Transactional Synchronization Extensions (Intel® TSX) Overview

Intel® Transactional Synchronization Extensions (Intel® TSX) allow the processor to determine dynamically whether threads need to serialize through lock-protected critical sections, and to perform serialization only when required. This lets the processor to expose and exploit concurrence hidden in an application due to dynamically unnecessary synchronization.

With Intel® TSX, programmer-specified code regions (also referred to as transactional regions) are executed transactionally. If the transactional execution completes successfully, then all memory operations performed within the transactional region will appear to have occurred instantaneously when viewed from other logical processors. A processor makes architectural updates performed within the region visible to other logical processors only on a successful commit, a process referred to as an atomic commit.

Intel® TSX also provides an `XTEST` instruction, allowing software to query whether the logical processor is transactionally executing in a transactional region identified by either Hardware Lock Elision (HLE) or Restricted Transactional Memory (RTM).

Since a successful transactional execution ensures an atomic commit, the processor executes the code region optimistically without explicit synchronization. If synchronization was unnecessary for that specific execution, execution can commit without any cross-thread serialization. If the processor cannot commit atomically, the optimistic execution fails. When this happens, the processor will roll back the execution, a process referred to as a transactional abort. On a transactional abort, the processor will discard all updates performed in the region, restore architectural state to appear as if the optimistic execution never occurred, and resume execution non-transactionally.

A processor can perform a transactional abort for numerous reasons. A primary cause is due to conflicting accesses between the transactionally executing logical processor and another logical processor. Such conflicting accesses may prevent a successful transactional execution. Memory addresses read from within a transactional region constitute the read-set of the transactional region and addresses written to within the transactional region constitute the write-set of the transactional region. Intel® TSX maintains the read- and write-sets at the granularity of a cache line. A conflicting access occurs if another logical processor either reads a location that is part of the transactional region’s write-set or writes a location that is a part of either the read- or write-set of the transactional region.

Conflicting access typically means serialization is required for this code region. Intel® TSX detects data conflicts at the granularity of a cache line, so unrelated data locations placed in the same cache line will be detected as conflicts. Transactional aborts may also occur due to limited transactional resources. The amount of data accessed in the region may exceed an implementation-specific capacity. Some instructions and system events may also cause transactional aborts. Frequent transactional aborts cause wasted cycles.

Intel® TSX provide two software interfaces to specify regions of code for transactional execution.

Hardware Lock Elision (HLE)

HLE is a legacy-compatible instruction set extension (comprising the `XACQUIRE` and `XRELEASE` prefixes) to specify transactional regions. HLE is for programmers who prefer the backward compatibility of the conventional mutual-exclusion programming model and would like to run HLE-enabled software on legacy hardware, but would like to take advantage of new lock elision capabilities on hardware with HLE support.

NOTE
Hardware Lock Elision (HLE) intrinsic functions apply to C/C++ applications for Windows* only.

Restricted Transactional Memory (RTM)

RTM is a new instruction set interface (comprising the `XBEGIN`, `XEND`, and `XABORT` instructions) for programmers to define transactional regions in a more flexible manner than that possible with HLE.

RTM is for programmers who prefer a flexible interface to the transactional execution hardware.

Intel® Transactional Synchronization Extensions (Intel® TSX) Programming Considerations

Typical programmer-identified regions are expected to transactionally execute and commit successfully. However, Intel® Transactional Synchronization Extensions (Intel® TSX) does not provide any such guarantee. A transactional execution may abort for many reasons. To take full advantage of the transactional capabilities, programmers should take into account programming considerations to increase the probability of their transactional execution committing successfully.

This section discusses various events that may cause transactional aborts. The architecture ensures that updates performed within a transaction that subsequently aborts execution will not become visible: Only a committed transactional execution updates architectural state. Transactional aborts never cause functional failures and only affect performance.

Instruction Based Considerations

Programmers can use any instruction safely inside a transaction, Hardware Lock Elision (HLE) or Restricted Transactional Memory (RTM) and can use transactions at any privilege level. Some instructions will always abort the transactional execution and cause execution to seamlessly and safely transition to a non-transactional path.

Intel® TSX allows for most common instructions to be used inside transactions without causing aborts. The following operations inside a transaction do not typically cause an abort:

- Operations on the instruction pointer register.
- Operations on general purpose registers (`GPR`s).
- Operations on the status flags (CF, OF, SF, PF, AF, and ZF).
- Operations on `XMM` and `YMM` registers.
- Operations on the `MXCSR` register.

> **NOTE**
> Programmers must be careful when intermixing Intel® Supplemental Streaming Extensions (Intel® SSE) and Intel® Advanced Vector Extensions (Intel® AVX) operations inside a transactional region. Intermixing Intel® SSE instructions accessing `XMM` registers and Intel® AVX instructions accessing `YMM` registers may cause transactions to abort.

Programmers may use `REP`/`REPNE` prefixed string operations inside transactions. However, long strings may cause aborts. Further, the use of `CLD` and `STD` instructions may cause aborts if they change the value of the DF flag. If DF is '1', the `STD` instruction will not cause an abort. Similarly, if DF is '0', the `CLD` instruction will not cause an abort.

Instructions not enumerated here as causing abort when used inside a transaction will typically not cause a transaction to abort (examples include but are not limited to `MFENCE`, `LFENCE`, `SFENCE`, `RDTSC`, `RDTSCP`, etc.).

The following instructions will abort transactional execution on any implementation:

- `XABORT`
- `CPUID`
- `PAUSE`

In some implementations, the following instructions may always cause transactional aborts. These instructions are not expected to be commonly used inside typical transactional regions. Programmers must not rely on these instructions to force a transactional abort, since whether they cause transactional aborts is implementation dependent.

- Operations on X87 and MMX™ architecture state. This includes all MMX™ and X87 instructions, including the `FXRSTOR` and `FXSAVE` instructions.
- **Update to non-status portion of EFLAGS:**`CLI`, `STI`, `POPFD`, `POPFQ`, `CLTS`.
- **Instructions that update segment registers, debug registers and/or control registers:**`MOV` to `DS`/`ES`/`FS`/`GS`/`SS`, `POPDS`/`ES`/`FS`/`GS`/`SS`, `LDS`, `LES`, `LFS`, `LGS`, `LSS`, `SWAPGS`, `WRFSBASE`, `WRGSBASE`, `LGDT`, `SGDT`, `LIDT`, `SIDT`, `LLDT`, `SLDT`, `LTR`, `STR`, `Far CALL`, `Far JMP`, `Far RET`, `IRET`, `MOV` to DRx, `MOV` to `CR0`/`CR2`/`CR3`/`CR4`/`CR8`, and `LMSW`.
- **Ring transitions:**`SYSENTER`, `SYSCALL`, `SYSEXIT`, and `SYSRET`.

- **TLB and Cacheability control:**`CLFLUSH`, `INVD`, `WBINVD`, `INVLPG`, `INVPCID`, and memory instructions with a non-temporal hint (`MOVNTDQA`, `MOVNTDQ`, `MOVNTI`, `MOVNTPD`, `MOVNTPS`, and `MOVNTQ`).
- **Processor state save:**`XSAVE`, `XSAVEOPT`, and `XRSTOR`.
- **Interrupts:**`INTn`, `INTO`.
- **IO:**`IN`, `INS`, `REP INS`, `OUT`, `OUTS`, `REP OUTS` and their variants.
- **VMX:** `VMPTRLD`, `VMPTRST`, `VMCLEAR`, `VMREAD`, `VMWRITE`, `VMCALL`, `VMLAUNCH`, `VMRESUME`, `VMXOFF`, `VMXON`, `INVEPT`, and `INVVPID`.
- **SMX:**`GETSEC`, `UD2`, `RSM`, `RDMSR`, `WRMSR`, `HLT`, `MONITOR`, `MWAIT`, `XSETBV`, `VZEROUPPER`, `MASKMOVQ`, and `V/MASKMOVDQU`.

Runtime Considerations

In addition to instruction-based considerations, runtime events may cause transactional execution to abort. These may be due to data access patterns or micro-architectural implementation causes. The following list is not a comprehensive discussion of all abort causes:

Any fault or trap in a transaction that must be exposed to software will be suppressed. Transactional execution will abort and execution will transition to a nontransactional execution as if the fault or trap had never occurred. If any exception is not masked, that will result in a transactional abort and it will be as if the exception had never occurred.

Synchronous exception events (#DE, #OF, #NP, #SS, #GP, #BR, #UD, #AC, #XF, #PF, #NM, #TS, #MF, #DB, #BP/INT3) that occur during transactional execution may cause an execution not to commit transactionally, and require a non-transactional execution. These events are suppressed as if they had never occurred. With HLE, since the non-transactional code path is identical to the transactional code path, these events will typically re-appear when the instruction that caused the exception is re-executed non-transactionally, causing the associated synchronous events to be delivered appropriately in the non-transactional execution.

Asynchronous events (NMI, SMI, INTR, IPI, PMI, etc.) occurring during transactional execution may cause the transactional execution to abort and transition to nontransactional execution. The asynchronous events will be queued and handled after the transactional abort is processed.

Transactions only support write-back cacheable memory type operations. A transaction may always abort if it includes operations on any other memory type. This includes instruction fetches to `UC` memory type.

Memory accesses within a transactional region may require the processor to set the Accessed and Dirty flags of the referenced page table entry. The behavior of how the processor handles this is implementation specific. Some implementations may allow the updates to these flags to become externally visible even if the transactional region subsequently aborts. Some Intel® TSX implementations may choose to abort the transactional execution if these flags need to be updated. Further, a processor's page-table walk may generate accesses to its own transactionally written but uncommitted state. Some Intel® TSX implementations may choose to abort the execution of a transactional region in such situations. The architecture ensures that if the transactional region aborts, the transactionally written state will not be made architecturally visible through the behavior of structures such as TLBs.

Executing self-modifying code transactionally may also cause transactional aborts. Programmers must continue to follow Intel recommended guidelines for writing self-modifying and cross-modifying code even when employing HLE and RTM.

While an implementation of RTM and HLE will typically provide sufficient resources for executing common transactional regions, implementation constraints and excessive sizes for transactional regions may cause a transactional execution to abort and transition to a non-transactional execution. The architecture provides no guarantee of the amount of resources available to do transactional execution and does not guarantee that a transactional execution will ever succeed.

Conflicting requests to a cache line accessed within a transactional region may prevent the transaction from executing successfully. For example, if logical processor *P0* reads line *A* in a transactional region and another logical processor *P1* writes *A* (either inside or outside a transactional region) then logical processor *P0* may abort if logical processor *P1*'s write interferes with processor *P0*'s ability to execute transactionally.

Similarly, if *P0* writes line *A* in a transactional region and *P1* reads or writes *A* (either inside or outside a transactional region), then *P0* may abort if *P1*'s access to *A* interferes with *P0*'s ability to execute transactionally. Other coherence traffic may at times appear as conflicting requests and may cause aborts. While these false conflicts may happen, they are expected to be uncommon. The conflict resolution policy to determine whether *P0* or *P1* aborts in the above scenarios implementation specific.

Intrinsics for Restricted Transactional Memory Operations

Restricted Transactional Memory Overview

Restricted Transactional Memory (RTM) provides a software interface for transactional execution. RTM provides three new instructions— `XBEGIN`, `XEND`, and `XABORT`—for programmers to start, commit, and abort transactional execution.

The programmer uses the `XBEGIN` instruction to specify the start of the transactional code region and the `XEND` instruction to specify the end of the transactional code region. The `XBEGIN` instruction takes an operand that provides a relative offset to the fallback instruction address if the RTM region could not be successfully executed transactionally.

A processor may abort RTM transactional execution for many reasons. The hardware automatically detects transactional abort conditions and restarts execution from the fallback instruction address with the architectural state corresponding to that at the start of the `XBEGIN` instruction and the `EAX` register updated to describe the abort status.

The `XABORT` instruction allows programmers to abort the execution of an RTM region explicitly. The `XABORT` instruction takes an 8-bit immediate argument that is loaded into the `EAX` register becoming available to software following an RTM abort.

RTM instructions do not have any data memory location associated with them. While the hardware provides no guarantees as to whether an RTM region will ever successfully commit transactionally, most transactions that follow the recommended guidelines are expected to successfully commit transactionally.

Programmers must always provide an alternative code sequence in the fallback path to guarantee the code completes execution. This may be as simple as acquiring a lock and executing the specified code region non-transactionally. Further, a transaction that always aborts on a given implementation may complete transactionally on a future implementation. Therefore, programmers must ensure the code paths for the transactional region and the alternative code sequence are functionally tested.

Detection of RTM Support

A processor supports RTM execution if CPUID.07H.EBX.RTM [bit 11] = 1. An application must check if the processor supports RTM before it uses the RTM instructions (`XBEGIN`, `XEND`, `XABORT`). These instructions will generate a #UD exception when used on a processor that does not support RTM.

RTM Abort Status Definition

RTM uses the `EAX` register to communicate abort status to software. Following an RTM abort the `EAX` register has the following definition.

EAX register bit position	**Meaning**
0	Set if abort caused by `XABORT` instruction.
1	If set, the transaction may succeed on a retry. This bit is always clear if bit '0' is set.

EAX register bit position	Meaning
2	Set if another logical processor conflicted with a memory address that was part of the transaction that aborted.
3	Set if an internal buffer overflowed.
4	Set if a debug breakpoint was hit.
5	Set if an abort occurred during execution of a nested transaction.
23:6	Reserved.
31:24	`XABORT` argument (only valid if bit '0' set, otherwise reserved).

The `EAX` abort status for RTM only provides the cause for aborts. It does not by itself encode whether an abort or commit occurred for the RTM region. The value of `EAX` can be '0' following an RTM abort. For example, a CPUID instruction when used inside an RTM region causes a transactional abort and may not satisfy the requirements for setting any of the `EAX` bits. This may result in an `EAX` value of '0'.

RTM Memory Ordering

A successful RTM commit causes all memory operations in the RTM region to appear to execute atomically. A successfully committed RTM region consisting of an `XBEGIN` followed by an `XEND`, even with no memory operations in the RTM region, has the same ordering semantics as a `LOCK` prefixed instruction. The `XBEGIN` instruction does not have fencing semantics. However, if an RTM execution aborts, all memory updates from within the RTM region are discarded and never made visible to any other logical processor.

Intel® Transactional Synchronization Extensions Programming Considerations

_xtest

Queries whether the processor is executing in a transactional region identified by restricted transactional memory (RTM) or hardware lock elision (HLE). The corresponding Intel® AVX2 instruction is `XTEST`*.*

Syntax

```
unsigned char _xtest(void);
```

Arguments

None.

Description

Queries the RTM or HLE execution status. If the `xtest` function is called inside an RTM or an active HLE region, then the `ZF` flag is cleared, else it is set.

NOTE

A processor supports the `xtest` instruction if it supports either HLE or RTM. An application must check either of these feature flags before using the `xtest` instruction. While the HLE prefixes are ignored on processors that do not support HLE, this instruction will generate a #UD exception when used on a processor that does not support either HLE or RTM.

Returns

Result of the query.

_xbegin

Specifies the start of a restricted transactional memory (RTM) code region and returns a value indicating status. The corresponding Intel® AVX2 instruction is `XBEGIN`*.*

Syntax

`unsigned int _xbegin(void);`

Arguments

None.

Description

Starts a RTM code region and returns a value indicating transaction successfully started or status from a transaction abort.

If the logical processor was not already in transactional execution, then the `xbegin` instruction causes the logical processor to start transactional execution. The `xbegin` instruction that transitions the logical processor into transactional execution is referred to as the outermost `xbegin` instruction.

The `xbegin` instruction specifies a relative offset to the fallback code path executed following a transactional abort. To promote proper program structure, this is not exposed in C++ code and the intrinsic function operates as if it invoked the following model code:

```
__inline unsigned int _xbegin() {
  unsigned status;
  __asm {
    move   eax, 0xFFFFFFFF
    xbegin _txnL1
    _txnL1:
    move   status, eax
  }
  return status;
}
```

When a transaction is successfully created the function will return 0xFFFFFFFF, which is never a valid status code for an aborted transaction. If the transaction aborts for any reason, the logical processor discards all architectural register and memory updates performed during the transaction execution and restores the architectural state to that corresponding to the outermost `xbegin` instruction. The EAX register is then updated with the status code of the aborted transaction, which can be used to transfer control to a fallback handler.

The instruction also specifies a relative offset to compute the address of the fallback code path following a transactional abort. On an RTM abort, the logical processor discards all architectural register and memory updates performed during the RTM execution and restores architectural state to that corresponding to the outermost `xbegin` instruction. The abort destination operand of the `xbegin` instruction is targeted to the following instruction so that there is no change in control flow whether the transaction aborts or not.

Returns

Returns value indicating transaction successfully started or status from a transaction abort.

_xend

Specifies the end of a restricted transactional memory (RTM) code region. The corresponding Intel® AVX2 instruction is `XEND`*.*

Syntax

`void _xend(void);`

Arguments

None.

Description

Specifies the end of restricted transactional memory code region. If this is the outermost transaction (including this `xend` instruction, the number of `xbegin` matches the number of `xend` instructions) then the processor will attempt to commit processor state automatically.

If the commit fails, the processor will rollback all register and memory updates performed during the RTM execution.

The logical processor will resume execution at the fallback address computed from the outermost `xbegin` instruction. The EAX register is updated to reflect RTM abort information. When `xend` is executed outside a transaction will cause a general protection fault (#GP).

The model instruction sequence for `xend` support is:

```
__inline void _xend() {
  __asm { xend }
}
```

Returns

Result of the query.

_xabort

Forces a restricted transactional memory (RTM) region to abort. The corresponding Intel® AVX2 instruction is `XABORT`*.*

Syntax

`void _xabort(const unsigned int imm);`

Arguments

None.

Description

Forces a RTM region to abort. All outstanding transactions are aborted and the logical processor resumes execution at the fallback address computed through the outermost `xbegin` transaction.

The EAX register is updated to reflect an `xabort` instruction caused the abort, and the imm8 argument will be provided in the upper eight bits of the return value (EAX register bits 31:24) containing the indicated immediate value. The argument of `xabort` function must be a compile time constant.

The model instruction sequence for `xabort` support is:

```
__inline void _xabort() {     __asm { xabort } }
```

Returns

Result of the query.

Intrinsics for Hardware Lock Elision Operations

Hardware Lock Elision Overview

> **NOTE**
> Hardware Lock Elision (HLE) intrinsic functions apply to C/C++ applications for Windows* only.

Hardware Lock Elision (HLE) provides a legacy compatible instruction set interface for transactional execution. HLE provides two new instruction prefix hints: `XACQUIRE` and `XRELEASE`.

The programmer uses the `XACQUIRE` prefix in front of the instruction that is used to acquire the lock that is protecting the critical section. The processor treats the indication as a hint to elide the write associated with the lock acquire operation. Even though the lock acquire has an associated write operation to the lock, the processor does not add the address of the lock to the transactional region's write-set nor does it issue any write requests to the lock. Instead, the address of the lock is added to the read-set and the logical processor enters transactional execution. If the lock was available before the `XACQUIRE` prefixed instruction, all other processors will continue to see it as available afterwards. Since the transactionally executing logical processor neither added the address of the lock to its write-set, nor performed externally visible write operations to it, other logical processors can read the lock without causing a data conflict. This allows other logical processors to enter and concurrently execute the lock-protected section. The processor automatically detects data conflicts that occur during the transactional execution and will perform a transactional abort if necessary.

The hardware ensures program order of operations on the lock, even though the eliding processor did not perform external write operations to the lock. If the eliding processor itself reads the value of the lock in the critical section, it will appear as if the processor had acquired the lock (the read will return the non-elided value). This behavior makes an HLE execution functionally equivalent to an execution without the HLE prefixes.

The programmer uses the `XRELEASE` prefix in front of the instruction that is used to release the lock protecting the critical section. This involves a write to the lock. If the instruction is restoring the value of the lock to the value it had prior to the `XACQUIRE` prefixed lock-acquire operation on the same lock, the processor elides the external write request associated with the release of the lock and does not add the address of the lock to the write-set. The processor then attempts to commit the transactional execution.

If multiple threads execute critical sections protected by the same lock, but they do not perform conflicting data operations, the threads can execute concurrently and without serialization. Even though the software uses lock acquisition operations on a common lock, the hardware recognizes this, elides the lock, and executes the critical sections on the two threads without requiring any communication through the lock — if such communication was dynamically unnecessary.

If the processor is unable to execute the region transactionally, it will execute the region non-transactionally and without elision. HLE-enabled software has the same forward progress guarantees as the underlying non-HLE lock-based execution. For successful HLE execution, the lock and the critical section code must follow certain guidelines. These guidelines only affect performance; not following these guidelines will not cause functional failure.

Hardware without HLE support will ignore the `XACQUIRE` and `XRELEASE` prefix hints and will not perform any elision. These prefixes correspond to the `REPNE`/`REPE` IA-32 architecture prefixes ignored on the instructions where `XACQUIRE` and `XRELEASE` are valid. Importantly, HLE is compatible with the existing lock-based programming model. Improper use of hints will not cause functional bugs though it may expose latent bugs already in the code.

Intel® Transactional Synchronization Extensions Programming Considerations

HLE Acquire _InterlockedCompareExchange Functions

Performs an atomic compare-and-exchange operation on the specified values and attempts to begin a HLE transaction if supported by the executing platform. This intrinsic function applies to C/C++ applications for Windows only.

Syntax

```
long _InterlockedCompareExchange_HLEAcquire(long volatile *Destination, long Exchange,
long Comparand);
```

```
__int64 _InterlockedCompareExchange64_HLEAcquire(__int64 volatile *Destination, __int64
Exchange, __int64 Comparand);
```

```
void * _InterlockedCompareExchangePointer_HLEAcquire(void * volatile *Destination, void
* Exchange, void * Comparand);
```

Parameters

`Destination [in, out]`	pointer to the destination value
`Exchange [in]`	value which will be written at Destination if the comparison matches.
`Comparand [in]`	value to compare to the value referenced by Destination.

Description

Performs an atomic compare-and-exchange operation on the specified values, and also attempts to begin a HLE transaction if the executing platform supports it.

These functions compare two specified values and replaces one of them with a third value if the compared values are equal.

Returns

Returns the initial value referenced by the `Destination` parameter.

HLE Acquire _InterlockedExchangeAdd Functions

Performs an atomic addition of two values and attempts to begin a HLE transaction if supported by the executing platform. This intrinsic function applies to C/C++ applications for Windows only.

Syntax

```
long _InterlockedExchangeAdd_HLEAcquire(long volatile *Addend, long Value);
```

```
__int64 _InterlockedExchangeAdd64_HLEAcquire(__int64 volatile *Addend, __int64 Value);
```

Parameters

`Addend [in, out]`	pointer to the addend which will be replaced with the result of the addition
`Value [in]`	value to be added to the value referenced by the `Addend`parameter

Description

Performs an atomic addition of two values, and also attempts to begin a HLE transaction if the executing platform supports it.

Returns

The function returns the initial value referenced by the `Addend` parameter.

HLE Release _InterlockedCompareExchange Functions

Performs an atomic compare-and-exchange operation on the specified values and releases pending active HLE transaction. This intrinsic function applies to C/C++ applications for Windows only.

Syntax

```
long _InterlockedCompareExchange_HLERelease(long volatile *Destination, long Exchange, long Comparand);
```

```
__int64 _InterlockedCompareExchange64_HLERelease(__int64 volatile *Destination, __int64 Exchange, __int64 Comparand);
```

```
void * _InterlockedCompareExchangePointer_HLERelease(void * volatile *Destination, void * Exchange, void * Comparand);
```

Parameters

`Destination [in, out]`	pointer to the destination value
`Exchange [in]`	value which will be written at Destination if the comparison matches.
`Comparand [in]`	value to compare to the value referenced by Destination.

Description

Performs an atomic compare-and-exchange operation on the specified values and releases a pending HLE transaction (if one is active).

The function compares two specified values and replaces one of them with a third value if the compared values are equal.

Returns

Returns the initial value referenced by the `Destination` parameter.

HLE Release _InterlockedExchangeAdd Functions

Performs an atomic addition of two values and releases pending active HLE transaction. This intrinsic function applies to C/C++ applications for Windows only.

Syntax

```
long _InterlockedExchangeAdd_HLERelease(long volatile *Addend, long Value);
```

```
__int64 _InterlockedExchangeAdd64_HLERelease(__int64 volatile *Addend, __int64 Value);
```

Parameters

`Addend [in, out]`	pointer to the addend which will be replaced with the result of the addition
`Value [in]`	value to be added to the value referenced by the `Addend` parameter

Description

Performs an atomic addition of two values and releases a pending HLE transaction (if one is active).

Returns

Returns the initial value referenced by the `Addend` parameter.

HLE Release _Store Functions

Stores the specified value at the specified address and releases pending active HLE transaction. This intrinsic function applies to C/C++ applications for Windows only.

Syntax

`void _Store_HLERelease(long volatile *Destination, long Value);`

`void _Store64_HLERelease(__int64 volatile *Destination, __int64 Value);`

`void _StorePointer_HLERelease(void * volatile *Destination, void * Value);`

Parameters

`Destination[out]`	pointer to the destination value
`Value [in]`	value to store at `Destination`.

Description

Stores the specified value at the specified address and releases a pending HLE transaction if one is active.

Returns

Nothing.

Function Prototype and Macro Definitions

To use the prototypes and macro definitions shown in Group 1, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Group 1: Function Prototypes:

```
unsigned int _xbegin(void);
void _xend(void);
void _xabort(const unsigned int imm);
unsigned char _xtest(void);
```

The following macro definitions are included in the `immintrin.h` header file:

Group 1: Macro Definitions:

```
#define _XBEGIN_STARTED (~0u)
#define _XABORT_EXPLICIT (1 << 0)
#define _XABORT_RETRY (1 << 1)
#define _XABORT_CONFLICT (1 << 2)
#define _XABORT_CAPACITY (1 << 3)
#define _XABORT_DEBUG (1 << 4)
#define _XABORT_NESTED (1 << 5)
```

Group 2: Function Macros

The following function Macros are *not* included in `immintrin.h` header file. If you want to use them, you need to define them in your applications.

For the HW with RTM support

```
#define __try_transaction(x) if ((x =_xbegin()) == _XBEGIN_STARTED)
#define __try_else _xend() } else
#define __transaction_abort(c) _xabort(c)
```

For the HW with no RTM support

```
#define __try_transaction(x) if (0) {
#define __try_else } else
#define __transaction_abort(c)
```

x is an unsigned integer type local variable for programmers to access RTM transaction abort code and holds the return value of `_xbegin()`. *c* is an unsigned integer compile-time constant value that is returned in the upper bits of *x* when `_xabort(c)` is executed.

A usage sample code of macros

```
 foo() { // user macros
int status;
__try_transaction (status) {
''' ''' '''
transaction code ….
 }
__try_else {
if (status & _XABORT_CONFLICT) {
 … code
}
}
}
```

Pseudo-ASM code

```
foo() { or eax 0xffffffff
xbegin L1 L1: mov status, eax
cmp eax 0xffffffff jnz
L2 transaction code

// when abort happens, HW restarts from L1
xend jmp L3 L2: abort
handler code L3: ret
}
```

The compiler will convert the macros to the instruction sequence with a proper branching for speculative execution path and alternative execution path.

The above example is similar to the usage example, except `__try_transaction` and `__try_else` macros are used instead of RTM intrinsic functions.

Intrinsics for Intel® Advanced Vector Extensions

Intel® Advanced Vector Extensions (Intel® AVX) intrinsics are assembly-coded functions that call on Intel® AVX instructions, which are new vector SIMD instruction extensions for IA-32 and Intel® 64 architectures. Intel® AVX intrinsics are architecturally similar to Intel® Streaming SIMD Extensions (Intel® SSE) and double-precision floating-point portions of Intel® Streaming SIMD Extensions 2 (Intel® SSE2).

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intel® AVX intrinsics introduce 256-bit vector processing capability, and are supported on IA-32 and Intel® 64 architectures built from 32nm process technology and beyond. They map directly to Intel® AVX new instructions and other enhanced 128-bit SIMD instructions.

The first generation Intel® AVX provides 256-bit SIMD register support, 256-bit vector floating-point instructions, enhancements to 128-bit SIMD instructions, and support for three and four operand syntax.

Functional Overview

Intel® AVX provides comprehensive functional improvements over previous generations of SIMD instruction extensions. The functional improvements include:

- **256-bit floating-point arithmetic primitives:** Intel® AVX enhances existing 128-bit floating-point arithmetic instructions with 256-bit capabilities for floating-point processing.
- **Enhancements for flexible SIMD data movements:** Intel® AVX provides a number of new data movement primitives to enable efficient SIMD programming in relation to loading non-unit-strided data into SIMD registers, intra-register SIMD data manipulation, conditional expression and branch handling, etc. Enhancements for SIMD data movement primitives cover 256-bit and 128-bit vector floating-point data, and across 128-bit integer SIMD data processing using VEX-encoded instructions.

Details about the Intel® AVX Intrinsics

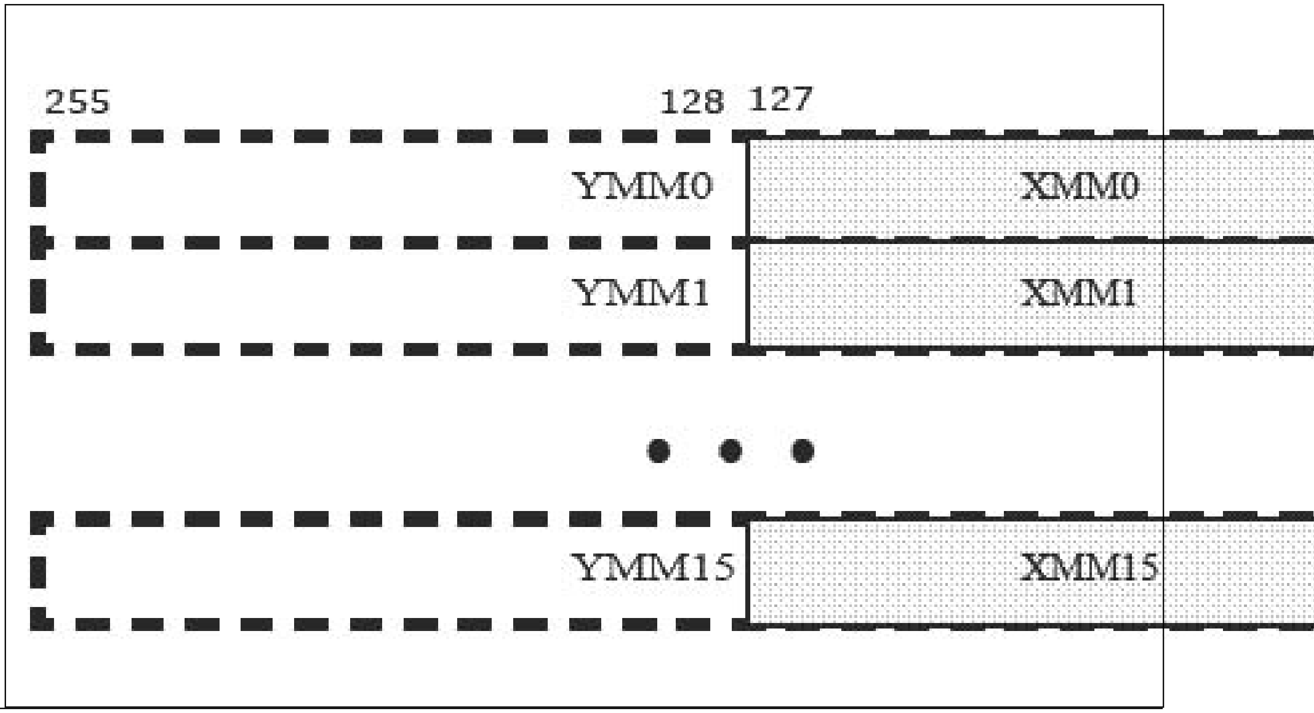
Details of Intel® Advanced Vector Extensions Intrinsics

Intel® Advanced Vector Extensions (Intel® AVX) intrinsics map directly to Intel® AVX instructions and other enhanced 128-bit single-instruction multiple data processing (SIMD) instructions. Intel® AVX instructions are architecturally similar to extensions of the existing Intel® 64 architecture-based vector streaming SIMD portions of Intel® Streaming SIMD Extensions (Intel® SSE) instructions, and double-precision floating-point portions of Intel® Streaming SIMD Extensions 2 (Intel® SSE2) instructions. However, Intel® AVX introduces the following architectural enhancements:

- Support for 256-bit wide vectors and SIMD register set.
- Instruction syntax support three and four operand syntax, to improve instruction programming flexibility and efficiency for new instruction extensions.
- Enhancement of legacy 128-bit SIMD instruction extensions to support three-operand syntax and to simplify compiler vectorization of high-level language expressions.
- Instruction encoding format using a new prefix (referred to as VEX) to provide compact, efficient encoding for three-operand syntax, vector lengths, compaction of legacy SIMD prefixes and REX functionality.
- Intel® AVX data types allow packing of up to 32 elements in a register if bytes are used. The number of elements depends upon the element type: eight single-precision floating point types or four double-precision floating point types.

Intel® Advanced Vector Extensions Registers

Intel® AVX adds 16 registers (`YMM0-YMM15`), each 256 bits wide, aliased onto the 16 SIMD (`XMM0-XMM15`) registers. The Intel® AVX new instructions operate on the `YMM` registers. Intel® AVX extends certain existing instructions to operate on the `YMM` registers, defining a new way of encoding up to three sources and one destination in a single instruction.



Because each of these registers can hold more than one data element, the processor can process more than one data element simultaneously. This processing capability is also known as single-instruction multiple data processing (SIMD).

For each computational and data manipulation instruction in the new extension sets, there is a corresponding C intrinsic that implements that instruction directly. This frees you from managing registers and assembly programming. Further, the compiler optimizes the instruction scheduling so that your executable runs faster.

Intel® Advanced Vector Extensions Types

The Intel® AVX intrinsic functions use three new C data types as operands, representing the new registers used as operands to the intrinsic functions. These are `__m256`, `__m256d`, and `__m256i` data types.

The `__m256` data type is used to represent the contents of the extended SSE register, the `YMM` register, used by the Intel® AVX intrinsics. The `__m256` data type can hold eight 32-bit floating-point values.

The `__m256d` data type can hold four 64-bit double precision floating-point values.

The `__m256i` data type can hold thirty-two 8-bit, sixteen 16-bit, eight 32-bit, or four 64-bit integer values.

The compiler aligns the `__m256`, `__m256d`, and `__m256i` local and global data to 32-byte boundaries on the stack. To align `integer`, `float`, or `double` arrays, use the `__declspec(align)` statement.

The Intel® AVX intrinsics also use Intel® SSE2 data types like `__m128`, `__m128d`, and `__m128i` for some operations. See Details of Intrinsics topic for more information.

VEX Prefix Instruction Encoding Support for Intel® AVX

Intel® AVX introduces a new prefix, referred to as VEX, in the Intel® 64 and IA-32 instruction encoding format. Instruction encoding using the VEX prefix provides several capabilities:

- direct encoding of a register operand within the VEX prefix.
- efficient encoding of instruction syntax operating on 128-bit and 256-bit register sets.
- compaction of REX prefix functionality.
- compaction of SIMD prefix functionality and escape byte encoding.

- providing relaxed memory alignment requirements for most VEX-encoded SIMD numeric and data processing instruction semantics with memory operand as compared to instructions encoded using SIMD prefixes.

The VEX prefix encoding applies to SIMD instructions operating on YMM registers, XMM registers, and in some cases with a general-purpose register as one of the operands. The VEX prefix is not supported for instructions operating on MMX™ or x87 registers.

It is recommended to use Intel® AVX intrinsics with option `[Q]xAVX`, because their corresponding instructions are encoded with the VEX-prefix. The `[Q]xAVX` option forces other packed instructions to be encoded with VEX too. As a result there are fewer performance stalls due to Intel® AVX to legacy Intel® SSE code transitions.

Naming and Usage Syntax

Most Intel® AVX intrinsic names use the following notational convention:

```
_mm256_<intrin_op>_<suffix>(<data type> <parameter1>, <data type> <parameter2>, <data type>
<parameter3>)
```

The following table explains each item in the syntax.

`_mm256/` `_mm128`	Prefix representing the size of the result. Usually, this corresponds to the Intel® AVX vector register size of 256 bits, but certain comparison and conversion intrinsics yield a 128-bit result.
`<intrin_op>`	Indicates the basic operation of the intrinsic; for example, add for addition and sub for subtraction.
`<suffix>`	Denotes the type of data the instruction operates on. The first one or two letters of each suffix denote whether the data is packed (*p*), extended packed (*ep*), or scalar (*s*). The remaining letters and numbers denote the type, with notation as follows: • **s:** single-precision floating point • **d:** double-precision floating point • **i128:** signed 128-bit integer • **i64:** signed 64-bit integer • **u64:** unsigned 64-bit integer • **i32:** signed 32-bit integer • **u32:** unsigned 32-bit integer • **i16:** signed 16-bit integer • **u16:** unsigned 16-bit integer • **i8:** signed 8-bit integer • **u8:** unsigned 8-bit integer • **ps:** packed single-precision floating point • **pd:** packed double-precision floating point • **sd:** scalar double-precision floating point • **epi32:** extended packed 32-bit integer • **si256:** scalar 256-bit integer
`<data type>`	Parameter data types: `__m256`, `__m256d`, `__m256i`, `__m128`, `__m128d`, `__m128i`, `const`, `int`, etc.
`<parameter1>`	Represents a source vector register: `m1`/`s1`/`a`
`<parameter2>`	Represents another source vector register: `m2`/`s2`/`b`
`<parameter3>`	Represents an integer value: `mask`/`select`/`offset`

The third parameter is an integer value whose bits represent a conditionality based on which the intrinsic performs an operation.

Example Usage

```
extern __m256d _mm256_add_pd(__m256d m1, __m256d m2);
```

where,

add	indicates that an addition operation must be performed
pd	indicates packed double-precision floating-point value

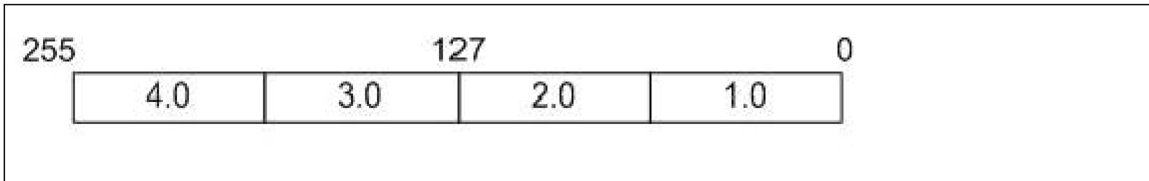
The packed values are represented in right-to-left order, with the lowest value used for scalar operations. Consider the following example operation:

```
double a[4] = {1.0, 2.0, 3.0, 4.0};
__m256d t = _mm256_load_pd(a);
```

The result is the following:

```
__m256d t = _mm256_set_pd(4.0, 3.0, 2.0, 1.0);
```

In other words, the `YMM` register that holds the value `t` appears as follows:



The " scalar " element is 1.0. Due to the nature of the instruction, some intrinsics require their arguments to be immediates (constant integer literals).

`__declspec(align)` declaration

Details of Intrinsics (general)

Intrinsics for Arithmetic Operations

_mm256_add_pd

Adds float64 vectors. The corresponding Intel® AVX instruction is `VADDPD`.

Syntax

```
extern __m256d _mm256_add_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation

Description

Performs a SIMD addition of four packed double-precision floating-point elements (float64 elements) in the first source vector *m1* with four float64 elements in the second source vector *m2*.

Returns

Result of the addition operation.

_mm256_add_ps

Adds float32 vectors. The corresponding Intel® AVX instruction is `VADDPS`*.*

Syntax

```
extern __m256 _mm256_add_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation

Description

Performs a SIMD addition of eight packed single-precision floating-point elements (float32 elements) in the first source vector *m1* with eight float32 elements in the second source vector *m2*.

Returns

Result of the addition operation.

_mm256_addsub_pd

Adds odd float64 elements and subtracts even float64 elements of vectors. The corresponding Intel® AVX instruction is `VADDSUBPD`*.*

Syntax

```
extern __m256d _mm256_addsub_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation

Description

Performs a SIMD addition of the odd packed double-precision floating-point elements (float64 elements) from the first source vector *m1* to the odd float64 elements of the second source vector *m2*.

Simultaneously, the intrinsic performs subtraction of the even double-precision floating-point elements of the second source vector *m2* from the even float64 elements of the first source vector *m1*.

Returns

Result of the operation is stored in the result vector, which is returned by the intrinsic.

_mm256_addsub_ps

Adds odd float32 elements and subtracts even float32 elements of vectors. The corresponding Intel® AVX instruction is `VADDSUBPS`*.*

Syntax

```
extern __m256 _mm256_addsub_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation

Description

Performs a SIMD addition of the odd single-precision floating-point elements (float32 elements) in the first source vector *m1* with the odd float32 elements in the second source vector *m2*.

Simultaneously, the intrinsic performs subtraction of the even single-precision floating-point elements (float32 elements) in the second source vector, *m2*, from the even float32 elements in the first source vector, *m1*.

Returns

Result of the operation stored in the result vector.

_mm256_hadd_pd

Adds horizontal pairs of float64 elements of two vectors. The corresponding Intel® AVX instruction is `VHADDPD`*.*

Syntax

```
extern __m256d _mm256_hadd_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation

Description

Performs a SIMD addition of adjacent (horizontal) pairs of double-precision floating-point elements (float64 elements) ins the first source vector *m1* with adjacent pairs of float64 elements in the second source vector *m2*.

Returns

Result of the addition operation.

_mm256_hadd_ps

Adds horizontal pairs of float32 elements of two vectors. The corresponding Intel® AVX instruction is `VHADDPS`*.*

Syntax

```
extern __m256 _mm256_hadd_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation

Description

Performs a SIMD addition of adjacent (horizontal) pairs of single-precision floating-point elements (float32 elements) in the first source vector *m1* with adjacent pairs of float32 elements in the second source vector *m2*.

Returns

Returns the result of the addition operation.

_mm256_sub_pd

Subtracts float64 vectors. The corresponding Intel® AVX instruction is `VSUBPD`*.*

Syntax

```
extern __m256d _mm256_sub_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation

Description

Performs a SIMD subtraction of four packed double-precision floating-point elements (float64 elements) of the second source vector *m2* from the first source vector *m1*.

Returns

Returns the result of the subtraction operation.

_mm256_sub_ps

Subtracts float32 vectors. The corresponding Intel® AVX instruction is `VSUBPS`*.*

Syntax

```
extern __m256 _mm256_sub_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation

Description

Performs a SIMD subtraction of eight packed single-precision floating-point elements (float32 elements) of the second source vector *m2* from the first source vector *m1*.

Returns

Returns the result of the subtraction operation.

_mm256_hsub_pd

Subtracts horizontal pairs of float64 elements of two vectors. The corresponding Intel® AVX instruction is `VHSUBPD`.

Syntax

```
extern __m256d _mm256_hsub_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation

Description

Performs a SIMD subtraction of adjacent (horizontal) pairs of double-precision floating-point elements (float64 elements) in the second source vector *m2* from adjacent pairs of float64 elements in the first source vector *m1*.

Returns

Result of the subtraction operation.

_mm256_hsub_ps

Subtracts horizontal pairs of float32 elements of two vectors. The corresponding Intel® AVX instruction is `VHSUBPS`.

Syntax

```
extern __m256 _mm256_hsub_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation

Description

Performs a SIMD subtraction of adjacent (horizontal) pairs of single-precision floating-point elements (float32 elements) in the second source vector *m2* from adjacent pairs of float32 elements in the first source vector *m1*.

Returns

Returns the result of the subtraction operation.

_mm256_mul_pd

Multiplies float64 vectors. The corresponding Intel® AVX instruction is `VMULPD`.

Syntax

```
extern __m256d _mm256_mul_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation

Description

Performs a SIMD multiplication of four packed double-precision floating-point elements (float64 elements) in the first source vector, *m1* , with four float64 elements in the second source vector, *m2*.

Returns

Result of the multiplication operation.

_mm256_mul_ps

Multiplies float32 vectors. The corresponding Intel® AVX instruction is `VMULPS`.

Syntax

```
extern __m256 _mm256_mul_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation

Description

Performs a SIMD multiplication of eight packed single-precision floating-point elements (float32 elements) in the first source vector *m1* with eight float32 elements in the second source vector *m2*.

Returns

Result of the multiplication operation.

_mm256_div_pd

Divides float64 vectors. The corresponding Intel® AVX instruction is `VDIVPD`.

Syntax

```
extern __m256d _mm256_div_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 vector used for the operation

m2	float64 vector also used for the operation

Description

Performs a SIMD division of four packed double-precision floating-point elements (float64 elements) in the first source vector *m1* with four float64 elements in the second source vector *m2*.

Returns

Result of the division operation.

_mm256_div_ps

Divides float32 vectors. The corresponding Intel® AVX instruction is `VDIVPS`*.*

Syntax

```
extern __m256 _mm256_div_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation

Description

Performs a SIMD division of eight packed single-precision floating-point elements (float32 elements) in the first source vector *m1* with eight float32 elements in the second source vector *m2*.

Returns

Result of the division operation.

_mm256_dp_ps

Calculates the dot product of float32 vectors. The corresponding Intel® AVX instruction is `VDPPS`*.*

Syntax

```
extern __m256 _mm256_dp_ps(__m256 m1, __m256 m2, const int mask);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation
mask	a constant of integer type where the high four bits of the mask determine how the resultant elements are summed and the low four bits determine whether the summed resultant value is to be broadcast to the destination vector or not

Description

First performs a SIMD multiplication of the lower four packed single-precision floating-point elements (float32 elements) from the first source vector *m1* with corresponding elements in the second source vector *m2*.

Each of the four resulting single-precision elements is conditionally summed depending on the high four bits in the *mask* parameter.

The resulting summed value is broadcast to each of the lower 4 positions in the destination vector, if the corresponding lower bit of the *mask* is "1". If the corresponding lower bit of the *mask* is zero, the corresponding lower element in the destination vector is set to zero.

The process is then replicated with the high elements of the source vectors.

Returns

Result of the operation.

_mm256_sqrt_pd

Computes the square root of double-precision floating point values. The corresponding Intel® AVX instruction is `VSQRTPD`*.*

Syntax

```
extern __m256d _mm256_sqrt_pd(__m256d a);
```

Arguments

a	float64 source vector

Description

Performs a SIMD computation of the square roots of the two or four packed double-precision floating-point values (float64 values) in the source vector and returns the result of the square root operation.

Returns

Result of the square root operation.

_mm256_sqrt_ps

Computes the square root of single-precision floating point values. The corresponding Intel® AVX instruction is `VSQRTPS`*.*

Syntax

```
extern __m256 _mm256_sqrt_ps(__m256 a);
```

Arguments

a	float32 source vector

Description

Performs a SIMD computation of the square roots of the eight packed single-precision floating-point values (float32 values) in the source vector and returns the result of the square root operation.

Returns

Result of the square root operation.

_mm256_rsqrt_ps

Computes approximate reciprocals of square roots of float32 values.The corresponding Intel® AVX instruction is `VRSQRTPS`*.*

Syntax

```
extern __m256 _mm256_rsqrt_ps(__m256 a);
```

Arguments

a	float32 source vector

Description

Performs a computation of the reciprocal of the square roots of eight single-precision floating point elements of the source vector *a* and returns the result as a vector.

Returns

Result of the reciprocal square root operation.

_mm256_rcp_ps

Computes approximate reciprocals of float32 values. The corresponding Intel® AVX instruction is `VRCPPS`*.*

Syntax

```
extern __m256 _mm256_rcp_ps(__m256 a);
```

Arguments

a	float32 source vector

Description

Performs a computation of the reciprocal of eight single-precision floating point elements of the source vector *a* and returns the result as a vector.

Returns

Result of the reciprocal operation.

Intrinsics for Bitwise Operations

_mm256_and_pd

Performs bitwise logical AND operation on float64 vectors. The corresponding Intel® AVX instruction is `VANDPD`*.*

Syntax

```
extern __m256d _mm256_and_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation

Description

Performs a bitwise logical AND of the four packed double-precision floating-point elements (float64 elements) of the first source vector *m1*, and corresponding elements in the second source vector *m2*.

Returns

Result of the bitwise operation.

_mm256_and_ps

Performs bitwise logical AND operation on float32 vectors. The corresponding Intel® AVX instruction is `VANDPS`.

Syntax

```
extern __m256 _mm256_and_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation

Description

Performs a bitwise logical AND of the eight packed single-precision floating-point elements (float32 elements) of the first source vector *m1*, and corresponding elements in the second source vector *m2.*

Returns

Result of the bitwise operation.

_mm256_andnot_pd

Performs bitwise logical AND NOT operation on float64 vectors. The corresponding Intel® AVX instruction is `VANDNPD`.

Syntax

```
extern __m256d _mm256_andnot_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation

Description

Performs a bitwise logical AND NOT of the four packed double-precision floating-point elements (float64 elements) of the first source vector *m1*, and corresponding elements in the second source vector *m2*.

Returns

Result of the bitwise operation.

_mm256_andnot_ps

Performs bitwise logical AND NOT operation on float32 vectors.The corresponding Intel© AVX instruction is `VANDNPS`.

Syntax

```
extern __m256 _mm256_andnot_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation

Description

Performs a bitwise logical AND NOT of the eight packed single-precision floating-point elements (float32 elements) of the first source vector *m1*, and corresponding elements in the second source vector *m2*.

Returns

Result of the bitwise operation.

_mm256_or_pd

Performs bitwise logical OR operation on float64 vectors. The corresponding Intel© AVX instruction is `VORPD`.

Syntax

```
extern __m256d _mm256_or_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation

Description

Performs a bitwise logical OR of the four packed double-precision floating-point elements (float64 elements) of the first source vector *m1*, and corresponding elements in the second source vector *m2*.

Returns

Result of the bitwise operation.

_mm256_or_ps

Performs bitwise logical OR operation on float32 vectors. The corresponding Intel© AVX instruction is `VORPS`.

Syntax

```
extern __m256 _mm256_or_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation

Description

Performs a bitwise logical OR of the eight packed single-precision floating-point elements (float32 elements) of the first source vector *m1*, and corresponding elements in the second source vector *m2*.

Returns

Result of the bitwise operation.

_mm256_xor_pd

Performs bitwise logical XOR operation on float64 vectors. The corresponding Intel® AVX instruction is `VXORPD`*.*

Syntax

```
extern __m256d _mm256_xor_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation

Description

Performs a bitwise logical XOR of the four packed double-precision floating-point elements (float64 elements) of the first source vector *m1*, and corresponding elements in the second source vector *m2*.

Returns

Result of the bitwise operation.

_mm256_xor_ps

Performs bitwise logical XOR operation on float32 vectors. The corresponding Intel® AVX instruction is `VXORPS`*.*

Syntax

```
extern __m256 _mm256_xor_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation

Description

Performs a bitwise logical XOR of the eight packed single-precision floating-point elements (float32 elements) of the first source vector *m1*, and corresponding elements in the second source vector, *m2*.

Returns

Result of the bitwise operation.

Intrinsics for Blend and Conditional Merge Operations

_mm256_blend_pd

Performs a conditional blend/merge of float64 vectors. The corresponding Intel© AVX instruction is `VBLENDPD`*.*

Syntax

```
extern __m256d _mm256_blend_pd(__m256d m1, __m256d m2, const int mask);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation
mask	a constant of integer type that is the mask for the operation

Description

Performs a conditional merge of four packed double-precision floating point elements (float64 elements) of two vectors according to the immediate bits of the *mask* parameter.

The *mask* parameter defines a constant integer. The immediate bits [3:0] in the *mask* determine from which source vector elements are copied into the resulting vector.

If the bits in *mask* are "1" then the corresponding elements of the second source vector are copied into the resulting vector. If the bits are "0" then the corresponding elements of the first source vector are copied into the resulting vector. Thus a merging/blending of the elements of the two source vectors occurs when this intrinsic is used.

Returns

Result of the merge/blend operation.

_mm256_blend_ps

Performs a conditional blend/merge of float32 vectors. The corresponding Intel© AVX instruction is `VBLENDPS`*.*

Syntax

```
extern __m256 _mm256_blend_ps(__m256 m1, __m256 m2, const int mask);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation

mask	a constant of integer type that is the mask for the operation

Description

Performs a conditional merge of eight packed single-precision floating point elements (float32 elements) of two vectors according to the immediate bits of the *mask* parameter.

The *mask* parameter defines a constant integer. The immediate bits [7:0] in the mask determine from which source vector elements are copied into the resulting vector.

If the bits in *mask* are "1" then the corresponding elements of the second source vector are copied into the resulting vector. If the bits are "0" then the corresponding elements of the first source vector are copied into the resulting vector. Thus a merging/blending of the elements of the two source vectors occurs when this intrinsic is used.

Returns

Result of the merge/blend operation.

_mm256_blendv_pd

Performs conditional blend/merge of float64 vectors. The corresponding Intel® AVX instruction is `VBLENDVPD`*.*

Syntax

```
extern __m256d _mm256_blendv_pd(__m256d m1, __m256d m2, __m256d mask);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation
mask	float64 vector with mask for the operation

Description

Performs a conditional merge of four packed double-precision floating point elements (float64 elements) of two vectors according to the most significant bits of the *mask* parameter elements.

The *mask* parameter defines a mask for the operation. The most significant bit of the corresponding double-precision floating-point elements in the *mask* determines whether the corresponding double-precision floating-point element in the resulting vector is copied from the second source or first source.

If the bit in the *mask* is "1" then the corresponding element of the second source vector is copied into the resulting vector. If the bit is "0" then the corresponding element of the first source vector is copied into the resulting vector. Thus a merging/blending of the elements of the two source vectors occurs when this intrinsic is used.

Returns

Result of the blend operation.

_mm256_blendv_ps

Performs conditional blend/merge of float32 vectors. The corresponding Intel® AVX instruction is `VBLENDVPS`*.*

Syntax

```
extern __m256 _mm256_blendv_ps(__m256 m1, __m256 m2, __m256 mask);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation
mask	float32 vector with the mask for the operation; defined such that the "1" in the most significant bits of an element indicate that corresponding elements of the second source vector are copied into the result, while "0" bits indicate that corresponding elements of the first source vector are copied into the result

Description

Performs a conditional merge of eight packed single-precision floating point elements (float32 elements) of two vectors according to the most significant bits of the *mask* parameter.

The *mask* parameter defines a mask for the operation. The most significant bit of the corresponding single-precision floating-point elements in the *mask* determines whether the corresponding single-precision floating-point element in the resulting vector is copied from the second source or first source.

If the bit in the *mask* is "1" then the corresponding element of the second source vector is copied into the resulting vector. If the bit is "0" then the corresponding element of the first source vector is copied into the resulting vector. Thus a merging/blending of the elements of the two source vectors occurs when this intrinsic is used.

Returns

Result of the blend operation.

Intrinsics for Compare Operations

_mm_cmp_pd, _mm256_cmp_pd

Compares packed 128-bit and 256-bit float64 vector elements. The corresponding Intel® AVX instruction is `VCMPPD`*.*

Syntax

```
extern __m128d _mm_cmp_pd(__m128d m1, __m128d m2, const int predicate);
extern __m256d _mm256_cmp_pd(__m256d m1, __m256d m2, const int predicate);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation
predicate	an immediate operand that specifies the type of comparison to be performed of the packed values; see `immintrin.h` file for the values to specify the type of comparison

Description

Performs a SIMD compare of the four packed double-precision floating-point (float64) values in the first source operand, *m1*, and the second source operand, *m2*, and returns the results of the comparison.

The `_mm_cmp_pd` intrinsic is used for comparing 128-bit float64 values while the `_m256_cmp_pd` intrinsic is used for comparing 256-bit float64 values.

The comparison *predicate* parameter (immediate) specifies the type of comparison performed on each of the pairs of packed values.

Returns

Result of the compare operation.

_mm_cmp_ps, _mm256_cmp_ps

Compares packed float32 elements of two vectors. The corresponding Intel® AVX instruction is `VCMPPS`*.*

Syntax

```
extern __m128 _mm_cmp_ps(__m128 m1, __m128 m2, const int predicate);
```

```
extern __m256 _mm256_cmp_ps(__m256 m1, __m256 m2, const int predicate);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation
predicate	an immediate operand that specifies the type of comparison to be performed of the packed values; see `immintrin.h` file for the values to specify the type of comparison

Description

Performs a SIMD compare of the eight packed single-precision floating-point (float32) values in the first source operand, *m1*, and the second source operand, *m2*, and returns the results of the comparison.

The `_mm_cmp_ps` intrinsic is used for comparing 128-bit float32 values while the `_mm256_cmp_ps` intrinsic is used for comparing 256-bit float32 values.

The comparison *predicate* parameter (immediate) specifies the type of comparison performed on each of the pairs of packed values.

Returns

Result of the compare operation.

_mm_cmp_sd

Compares scalar float64 vectors. The corresponding Intel® AVX instruction is `VCMPSD`*.*

Syntax

```
extern __m128d _mm_cmp_sd(__m128d m1, __m128d m2, const int predicate);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation
predicate	an immediate operand that specifies the type of comparison to be performed of the packed values; see `immintrin.h` file for the values to specify the type of comparison

Description

Performs a compare operation of the low double-precision floating-point values (float64 values) in the first source operand, *m1*, and the second source operand, *m2*, and returns the result.

The comparison *predicate* parameter (immediate operand) specifies the type of comparison performed on each of the pairs of values.

Returns

Result of the compare operation.

_mm_cmp_ss

Compares scalar float32 values. The corresponding Intel© AVX instruction is `VCMPSS`*.*

Syntax

```
extern __m128 _mm_cmp_ss(__m128 m1, __m128 m2, const int predicate);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation
predicate	an immediate operand that specifies the type of comparison to be performed of the packed values; see `immintrin.h` file for the values to specify the type of comparison

Description

Performs a compare operation of the low single-precision floating-point values (float32 values) in the first source operand, *m1*, and the second source operand, *m2*, and returns the results.

The comparison predicate parameter (immediate) specifies the type of comparison performed.

Returns

Result of the compare operation.

Intrinsics for Conversion Operations

_mm256_cvtepi32_pd

Converts extended packed 32-bit integer values to packed double-precision floating point values.The corresponding Intel® AVX instruction is `VCVTDQ2PD`*.*

Syntax

```
extern __m256 _mm256_cvtepi32_pd(__m128i m1);
```

Arguments

m1	integer source vector/operand

Description

Converts four packed signed doubleword integers in the source vector *m1* into four packed double-precision floating-point values.

Returns

Result of the conversion operation.

_mm256_cvtepi32_ps

Converts extended packed 32-bit integer values to packed single-precision floating point values. The corresponding Intel® AVX instruction is `VCVTDQ2PS`*.*

Syntax

```
extern __m256 _mm256_cvtepi32_ps(__m256i m1);
```

Arguments

m1	integer source vector /operand

Description

Converts eight packed signed doubleword integers in the source vector *m1* to eight packed single-precision floating-point values.

Returns

Result of the conversion operation.

_mm256_cvtpd_epi32

Converts packed double-precision float values to extended 32-bit integer values.The corresponding Intel® AVX instruction is `VCVTPD2DQ`*.*

Syntax

```
extern __m128i _mm256_cvtpd_epi32(__m256d m1);
```

Arguments

m1	float64 source vector

Description

Converts four packed double-precision floating-point values in the source vector *m1* to four packed signed doubleword integer (extended 32-bit integer) values in the destination.

Returns

Result of the conversion operation.

_mm256_cvtps_epi32

Converts packed single-precision float values to extended 32-bit integer values. The corresponding Intel® AVX instruction is `VCVTPS2DQ`*.*

Syntax

```
extern __m256i _mm256_cvtps_epi32(__m256 m1);
```

Arguments

m1	float32 source vector

Description

Converts eight packed single-precision floating point values in the source vector *m1* to eight signed doubleword integer (extended 32-bit integer) values.

Returns

Result of the conversion operation.

_mm256_cvtpd_ps

Converts packed float64 values to packed float32 values. The corresponding Intel® AVX instruction is `VCVTPD2PS`*.*

Syntax

```
extern __m128 _mm256_cvtpd_ps(__m256d m1);
```

Arguments

m1	float64 source vector

Description

Converts four packed double-precision floating point values (float64 values) in the source vector *m1* to eight packed single-precision floating-point values (float32 values).

Returns

Result of the conversion operation.

_mm256_cvtps_pd

Converts packed float32 values to packed floati64 values. The corresponding Intel® AVX instruction is `VCVTPS2PD`*.*

Syntax

```
extern __m256d _mm256_cvtps_pd(__m128 m1);
```

Arguments

m1	128-bit float32 source vector

Description

Converts four packed single-precision floating point values (float32 values) in the source vector *m1* to four packed double-precision floating point values (float64 values).

Returns

Result of the conversion operation.

_mm256_cvttp_epi32

Converts packed float64 values to truncated extended 32-bit integer values. The corresponding Intel® AVX instruction is `VCVTTPD2DQ`*.*

Syntax

```
extern __m128i _mm256_cvttpd_epi32(__m256d m1);
```

Arguments

m1	float64 source vector

Description

Converts four packed double-precision floating-point values (float64 values) in the source vector to four packed signed doubleword integer (extended 32-bit integer) values in the destination.

When a conversion is inexact, a truncated (round towards zero) value is returned. If a converted result is larger than the maximum signed doubleword integer, the floating-point invalid exception is raised. If this exception is masked, the indefinite integer value (80000000H) is returned.

Returns

Result of the conversion operation.

_mm256_cvttps_epi32

Converts packed float32 values to truncated extended 32-bit integer values. The corresponding Intel® AVX instruction is `VCVTTPS2DQ`*.*

Syntax

```
extern __m256i _mm256_cvttps_epi32(__m256 m1);
```

Arguments

m1	float32 source vector

Description

Converts eight packed single-precision floating-point values (float32 values) in the source vector to eight packed signed doubleword integer (extended 32-bit integer) values in the destination.

When a conversion is inexact, a truncated (round towards zero) value is returned. If a converted result is larger than the maximum signed doubleword integer, the floating-point invalid exception is raised; if this exception is masked, the indefinite integer value (80000000H) is returned.

Returns

Result of the conversion operation.

_mm256_cvtsi256_si32

Extracts a 32-bit integer value.

Syntax

```
int _mm256_cvtsi256_si32(__m256i a);
```

Arguments

a	256-bit integer source vector

Description

Copies the least significant 32 bits of *a* to a 32-bit integer.

Returns

Result of the conversion operation.

_mm256_cvtsd_f64

Extracts a double precision floating point value.

Syntax

```
double _mm256_cvtsd_f64(__m256d a);
```

Arguments

a	float64 source vector

Description

This intrinsic extracts a double precision floating point value from the first vector element of an `__m256d`. It does so in the most efficient manner possible in the context used.

Returns

Result of the conversion operation.

_mm256_cvtss_f32

Extracts a single precision floating point value.

Syntax

```
float _mm256_cvtss_f32(__m256 a);
```

Arguments

a	float32 source vector

Description

Extracts a single precision floating point value from the first vector element of an `__m256`. It does so in the most efficient manner possible in the context used.

Returns

Result of the conversion operation.

Intrinsics to Determine Minimum and Maximum Values

_mm256_max_pd

Determines the maximum of float64 vectors. The corresponding Intel© AVX instruction is `VMAXPD`.

Syntax

```
extern __m256d _mm256_max_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation

Description

Performs a SIMD compare of the packed double-precision floating-point (float64) elements in the first source vector *m1* and the second source vector *m2*, and returns the maximum value for each pair.

Returns

Maximum value of the compare operation.

_mm256_max_ps

Determines the maximum of float32 vectors. The corresponding Intel© AVX instruction is `VMAXPS`.

Syntax

```
extern __m256 _mm256_max_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation

Description

Performs a SIMD compare of the packed single-precision floating-point (float32) elements in the first source vector *m1* and the second source vector *m2*, and returns the maximum value for each pair.

Returns

Maximum value of the compare operation.

_mm256_min_pd

Determines the minimum of float64 vectors. The corresponding Intel® AVX instruction is `VMINPD`*.*

Syntax

```
extern __m256d _mm256_min_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation

Description

Performs a SIMD compare of the packed double-precision floating-point (float64) elements in the first source vector *m1* and the second source vector *m2*, and returns the minimum value for each pair.

Returns

Minimum value of the compare operation.

_mm256_min_ps

Determines the minimum of float32 vectors.The corresponding Intel® AVX instruction is `VMINPS`*.*

Syntax

```
extern __m256 _mm256_min_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation

Description

Performs a SIMD compare of the packed single-precision floating-point (float32) elements in the first source vector *m1* and the second source vector *m2*, and returns the minimum value for each pair.

Returns

Minimum value of the compare operation.

Intrinsics for Load and Store Operations

_mm256_broadcast_pd

Loads and broadcasts packed double-precision floating point values.The corresponding Intel® AVX instruction is `VBROADCASTF128`*.*

Syntax

```
extern __m256d _mm256_broadcast_pd(__m128d const *a);
```

Arguments

**a*	pointer to a memory location that can hold constant float64 values

Description

Loads 128-bit float64 values from the specified address pointed to by *a*, and broadcasts it to two elements in the destination 256-bit vector.

Returns

Result of the load and broadcast operation.

_mm256_broadcast_ps

Loads and broadcasts packed single-precision floating point values. The corresponding Intel® AVX instruction is `VBROADCASTF128`*.*

Syntax

```
extern __m256 _mm256_broadcast_ps(__m128 const *a);
```

Arguments

**a*	pointer to a memory location that can hold constant 128-bit float32 values

Description

Loads 128-bit float32 values from the specified address pointed to by *a*, and broadcasts it to all elements in the destination 256-bit vector.

Returns

Result of the load and broadcast operation.

_mm256_broadcast_sd

Loads and broadcasts scalar double-precision floating point values to a 256-bit destination operand. The corresponding Intel® AVX instruction is `VBROADCASTSD`*.*

Syntax

```
extern __m256d _mm256_broadcast_sd(double const *a);
```

Arguments

**a*	pointer to a memory location that can hold constant scalar float64 values

Description

Loads scalar double-precision floating-point values from the specified address *a*, and broadcasts it to all four elements in the destination vector.

Returns

Result of the load and broadcast operation.

_mm256_broadcast_ss, _mm_broadcast_ss

Loads and broadcasts 256/128-bit scalar single-precision floating point values to a 256/128-bit destination operand. The corresponding Intel® AVX instruction is `VBROADCASTSS`.

Syntax

```
extern __m256 _mm256_broadcast_ss(float const *a);
```

```
extern __m128 _mm_broadcast_ss(float const *a);
```

Arguments

**a*	pointer to a memory location that can hold constant 256-bit or 128-bit float32 values

Description

Loads scalar single-precision floating-point values from the specified address pointed to by *a*, and broadcasts it to elements in the destination vector.

The `_m256_broadcast_ss` intrinsic broadcasts the loaded values to all eight elements in the 256-bit destination vector.

The `_mm_broadcast_ss` intrinsic broadcasts the loaded values to all four elements in the 128-bit destination vector.

Returns

Result of the load and broadcast operation.

_mm256_load_pd

Moves packed double-precision floating point values from aligned memory location to a destination vector. The corresponding Intel® AVX instruction is`VMOVAPD`.

Syntax

```
extern __m256d _mm256_load_pd(double const *a);
```

Arguments

**a*	pointer to a memory location that can hold constant float64 values; the address must be 32-byte aligned

Description

Loads packed double-precision floating point values (float64 values) from the 256-bit aligned memory location pointed to by *a*, into a destination float64 vector, which is retured by the intrinsic.

Returns

A 256-bit vector with float64 values.

_mm256_load_ps

Moves packed single-precision floating point values from aligned memory location to a destination vector. The corresponding Intel© AVX instruction is`VMOVAPS`*.*

Syntax

```
extern __m256 _mm256_load_ps(float const *a);
```

Arguments

**a*	pointer to a memory location that can hold constant float32 values; the address must be 32-byte aligned

Description

Loads packed single-precision floating point values (float32 values) from the 256-bit aligned memory location pointed to by *a*, into a destination float32 vector, which is retured by the intrinsic.

Returns

A 256-bit vector with float32 values.

_mm256_load_si256

Moves integer values from aligned memory location to a destination vector. The corresponding Intel© AVX instruction is`VMOVDQA`*.*

Syntax

```
extern __m256i _mm256_load_si256(__m256i const *a);
```

Arguments

**a*	pointer to a memory location that can hold constant integer values; the address must be 32-byte aligned

Description

Loads integer values from the 256-bit aligned memory location pointed to by **a*, into a destination integer vector, which is returned by the intrinsic.

Returns

A 256-bit vector with integer values.

_mm256_loadu_pd

Moves packed double-precision floating point values from unaligned memory location to a destination vector. The corresponding Intel© AVX instruction is `VMOVUPD`*.*

Syntax

```
extern __m256d _mm256_loadu_pd(double const *a);
```

Arguments

**a*	pointer to a memory location that can hold constant float64 values;

Description

Loads packed double-precision floating point values (float64 values) from the 256-bit unaligned memory location pointed to by *a*, into a destination float64 vector, which is retured by the intrinsic.

Returns

A 256-bit vector with float64 values.

_mm256_loadu_ps

Moves packed single-precision floating point values from unaligned memory location to a destination vector. The corresponding Intel® AVX instruction is`VMOVUPS`*.*

Syntax

```
extern __m256 _mm256_loadu_ps(float const *a);
```

Arguments

**a*	pointer to a memory location that can hold constant float32 values

Description

Loads packed single-precision floating point values (float32 values) from the 256-bit unaligned memory location pointed to by *a*, into a destination float32 vector, which is retured by the intrinsic.

Returns

A 256-bit vector with float32 values.

_mm256_loadu_si256

Moves integer values from unaligned memory location to a destination vector. The corresponding Intel® AVX instruction is`VMOVDQU`*.*

Syntax

```
extern __m256i _mm256_loadu_si256(__m256i const *a);
```

Arguments

**a*	pointer to a memory location that can hold constant integer values

Description

Loads integer values from the 256-bit unaligned memory location pointed to by **a*, into a destination integer vector, which is returned by the intrinsic.

Returns

A 256-bit vector with integer values.

_mm256_maskload_pd, _mm_maskload_pd

Loads packed double-precision floating point values according to mask values. The corresponding Intel® AVX instruction is `VMASKMOVPD`.

Syntax

```
extern __m256d _mm256_maskload_pd(double const *a, __m256i mask);
```

```
extern __m128d _mm_maskload_pd(double const *a, __m128i mask);
```

Arguments

**a*	pointer to a 256/128-bit memory location that can hold constant float64 values
mask	integer value calculated based on the most-significant-bit of each quadword of a mask register

Description

Loads packed double-precision floating point (float64) values from the 256/128-bit memory location pointed to by *a*, into a destination register using the *mask* value.

The *mask* is calculated from the most significant bit of each qword of the *mask* register. If any of the bits of the *mask* is set to zero, the corresponding value from the memory location is not loaded, and the corresponding field of the destination vector is set to zero.

Returns

A 256/128-bit register with float64 values.

_mm256_maskload_ps, _mm_maskload_ps

Loads packed single-precision floating point values according to mask values. The corresponding Intel® AVX instruction is `VMASKMOVPS`.

Syntax

```
extern __m256 _mm256_maskload_ps(float const *a, __m256i mask);
```

```
extern __m128 _mm_maskload_ps(float const *a, __m128i mask);
```

Arguments

**a*	pointer to a 256/128-bit memory location that can hold constant float32 values
mask	integer value calculated based on the most-significant-bit of each doubleword of a mask register

Description

Loads packed single-precision floating point (float32) values from the 256/128-bit memory location pointed to by *a*, into a destination register using the *mask* value.

The *mask* is calculated from the most significant bit of each dword of the *mask* register. If any of the bits of the *mask* is set to zero, the corresponding value from the memory location is not loaded, and the corresponding field of the destination vector is set to zero.

Returns

A 256/128-bit register with float32 values.

_mm256_store_pd

Moves packed double-precision floating point values from a float64 vector to an aligned memory location. The corresponding Intel© AVX instruction is`VMOVAPD`*.*

Syntax

```
extern void _mm256_store_pd(double *a, __m256d b);
```

Arguments

**a*	pointer to a memory location that can hold double-precision floating point (float64) values; the address must be 32-byte aligned
b	float64 vector

Description

Performs a store operation by moving packed double-precision floating point values (float64 values) from a float64 vector, *b*, to a 256-bit aligned memory location, pointed to by *a*.

Returns

Nothing

_mm256_store_ps

Moves packed single-precision floating point values from a float32 vector to an aligned memory location. The corresponding Intel© AVX instruction is`VMOVAPS`*.*

Syntax

```
extern void _mm256_store_ps(float *a, __m256 b);
```

Arguments

**a*	pointer to a memory location that can hold single-precision floating point (float32) values; the address must be 32-byte aligned
b	float32 vector

Description

Performs a store operation by moving packed single-precision floating point values (float32 values) from a float32 vector, *b*, to a 256-bit aligned memory location, pointed to by *a*.

Returns

Nothing.

_mm256_store_si256

Moves values from a integer vector to an aligned memory location. The corresponding Intel® AVX instruction is `VMOVDQA`*.*

Syntax

```
extern void _mm256_store_si256(__m256i *a, __m256i b);
```

Arguments

**a*	pointer to a memory location that can hold scalar integer values; the address must be 32-byte aligned.
b	integer vector

Description

Performs a store operation by moving integer values from a 256-bit integer vector, *b*, to a 256-bit aligned memory location, pointed to by *a*.

Returns

Nothing.

_mm256_storeu_pd

Moves packed double-precision floating point values from a float64 vector to an unaligned memory location. The corresponding Intel® AVX instruction is`VMOVUPD`*.*

Syntax

```
extern void _mm256_storeu_pd(double *a, __m256d b);
```

Arguments

**a*	pointer to a memory location that can hold double-precision floating point (float64) values
b	float64 vector

Description

Performs a store operation by moving packed double-precision floating point values (float64 values) from a float64 vector, *b*, to a 256-bit unaligned memory location, pointed to by *a*.

Returns

Nothing.

_mm256_storeu_ps

Moves packed single-precision floating point values from a float32 vector to an unaligned memory location. The corresponding Intel® AVX instruction is`VMOVUPS`*.*

Syntax

```
extern void _mm256_storeu_ps(float *a, __m256 b);
```

Arguments

**a*	pointer to a memory location that can hold single-precision floating point (float32) values
b	float32 vector

Description

Performs a store operation by moving packed single-precision floating point values (float32 values) from a float32 vector, *b*, to a 256-bit unaligned memory location, pointed to by *a*.

Returns

Nothing.

_mm256_storeu_si256

Moves values from a integer vector to an unaligned memory location. The corresponding Intel® AVX instruction is `VMOVDQU`*.*

Syntax

```
extern void _mm256_storeu_si256(__m256i *a, __m256i b);
```

Arguments

**a*	pointer to a memory location that can hold scalar integer values
b	integer vector

Description

Performs a store operation by moving integer values from a 256-bit integer vector, *b*, to a 256-bit unaligned memory location, pointed to by *a*.

Returns

Nothing.

_mm256_stream_pd

Moves packed double-precision floating-point values using non-temporal hint. The corresponding Intel® AVX instruction is `VMOVNTPD`*.*

Syntax

```
extern void _mm256_stream_pd(double *p, __m256d a);
```

Arguments

**p*	pointer to a memory location that can hold double-precision floating point (float64) values; the address must be 32-byte aligned
a	float64 vector

Description

Performs a store operation by moving packed double-precision floating point values (float64 values) from a float64 vector, *a*, to a 256-bit aligned memory location, pointed to by *p*, using a non-temporal hint to prevent caching of the data during the write to memory.

Returns

Result of the streaming/store operation.

_mm256_stream_ps

Moves packed single-precision floating-point values using non-temporal hint. The corresponding Intel® AVX instruction is `VMOVNTPS`*.*

Syntax

```
extern void _mm256_stream_ps(float *p, __m256 a);
```

Arguments

**p*	pointer to a memory location that can hold single-precision floating point (float32) values; the address must be 32-byte aligned
a	float32 vector

Description

Performs a store operation by moving packed single-precision floating point values (float32 values) from a float32 vector, *a*, to a 256-bit aligned memory location, pointed to by *p*, using a non-temporal hint to prevent caching of the data during the write to memory.

Returns

Result of the streaming/store operation.

_mm256_stream_si256

Moves packed integer values using non-temporal hint. The corresponding Intel® AVX instruction is `VMOVNTDQ`*.*

Syntax

```
extern void _mm256_stream_si256(__m256i *p, __m256i a);
```

Arguments

**p*	pointer to a memory location that can hold scalar integer values; the address must be 32-byte aligned

a	integer vector

Description

Performs a store operation by moving scalar integer values from an integer vector *a*, to a 256-bit aligned memory location, pointed to by *p*, using a non-temporal hint to prevent caching of the data during the write to memory.

Returns

Result of the streaming/store operation.

_mm256_maskstore_pd, _mm_maskstore_pd

Stores packed double-precision floating point values according to mask values. The corresponding Intel® AVX instruction is `VMASKMOVPD`*.*

Syntax

```
extern void _mm256_maskstore_pd(double *a, __m256i mask, __m256d b);
```

```
extern void _mm_maskstore_pd(double *a, __m128i mask, __m128d b);
```

Arguments

**a*	pointer to a 256/128-bit memory location that can hold constant double-precision floating point (float64) values
mask	integer value calculated based on the most-significant-bit of each quadword of a mask register
b	a 256/128-bit float64 vector

Description

Performs a store operation by moving packed double-precision floating point (float64) values from a vector, *b*, to a 256/128-bit memory location, pointed to by *a*, using a *mask*.

The *mask* is calculated from the most significant bit of each qword of the *mask* register. If any of the bits of the mask are set to zero, the corresponding value from the float64 vector is not loaded, and the corresponding field of the destination memory location is left unchanged.

> **NOTE**
> Stores are atomic. Faults do not occur for memory locations for which all corresponding mask bits are set to zero.

Returns

Nothing.

_mm256_maskstore_ps, _mm_maskstore_ps

Stores packed single-precision floating point values according to mask values. The corresponding Intel® AVX instruction is `VMASKMOVPS`*.*

Syntax

```
extern void _mm256_maskstore_ps(float *a, __m256i mask, __m256 b);
```

```
extern void _mm_maskstore_ps(float *a, __m128i mask, __m128 b);
```

Arguments

**a*	pointer to a 256/128-bit memory location that can hold constant single-precision floating point (float32) values
mask	integer value calculated based on the most-significant-bit of each quadword of a mask register
b	a 256/128-bit float32 vector

Description

Performs a store operation by moving packed single-precision floating point (float32) values from a vector, *b*, to a 256/128-bit memory location, pointed to by *a*, using a *mask*.

The *mask* is calculated from the most significant bit of each qword of the *mask* register. If any of the bits of the mask are set to zero, the corresponding value from the float32 vector is not loaded, and the corresponding field of the destination memory location is left unchanged.

> **NOTE**
> Stores are atomic. Faults do not occur for memory locations for which all corresponding mask bits are set to zero.

Returns

Nothing.

Intrinsics for Miscellaneous Operations

_mm256_extractf128_pd

Extracts 128-bit packed float64 values. The corresponding Intel© AVX instruction is `VEXTRACTF128`*.*

Syntax

```
extern __m128d _mm256_extractf128_pd(__m256d m1, const int offset);
```

Arguments

m1	float64 source vector
offset	a constant integer value that represents the 128-bit offset from where extraction must start

Description

Extracts 128-bit packed double-precision floating point values (float64 values) from the source vector *m1*, starting from the location specified by the value in the *offset* parameter.

Returns

Result of the extraction operation.

_mm256_extractf128_ps

Extracts 128-bit float32 values. The corresponding Intel© AVX instruction is `VEXTRACTF128`.

Syntax

```
extern __m128 _mm256_extractf128_ps(__m256 m1, const int offset);
```

Arguments

m1	float32 source vector
offset	a constant integer value that represents the 128-bit offset from where extraction must start

Description

Extracts 128-bit packed single-precision floating point values (float32 values) from the source vector *m1*, starting from the location specified by the value in the *offset* parameter.

Returns

Result of the extraction operation.

_mm256_extractf128_si256

Extracts 128-bit scalar integer values. The corresponding Intel© AVX instruction is `VEXTRACTF128`.

Syntax

```
extern __m128i _mm256_extractf128_si256(__m256i m1, const int offset);
```

Arguments

m1	integer source vector
offset	a constant integer value that represents the offset from where extraction must start

Description

Extracts 128-bit scalar integer values from the source vector *m1*, starting from the location specified by the value in the *offset* parameter.

Returns

Result of the extraction operation.

_mm256_insertf128_pd

Inserts 128 bits of packed float64 values. The corresponding Intel© AVX instruction is `VINSERTF128`.

Syntax

```
extern __m256d _mm256_insertf128_pd(__m256d a, __m128d b, int offset);
```

Arguments

a	256-bit float64 source vector
b	128-bit float64 source vector
offset	an integer value that represents the 128-bit offset where the insertion must start

Description

Performs an insertion of 128 bits of packed double-precision floating-point values (float64 values) from the second source vector *b* into a destination at a 128-bit offset specified by the *offset* parameter. The remaining portions of the destination are written by the corresponding elements of the first source vector *a*.

Returns

Result of the insertion operation.

_mm256_insertf128_ps

Inserts 128 bits of packed float32 values. The corresponding Intel® AVX instruction is `VINSERTF128`*.*

Syntax

```
extern __m256 _mm256_insertf128_ps(__m256 a, __m128 b, int offset);
```

Arguments

a	256-bit float32 source vector
b	128-bit float32 source vector
offset	an integer value that represents the 128-bit offset where the insertion must start

Description

Performs an insertion of 128 bits of packed single-precision floating-point values (float32 values) from the second source vector *b*, into a destination at a 128-bit offset specified by the *offset* parameter. The remaining portions of the destination are written by the corresponding elements of the first source vector *a*.

Returns

Result of the insertion operation.

_mm256_insertf128_si256

Inserts 128 bits of packed scalar integer values . The corresponding Intel® AVX instruction is `VINSERTF128`*.*

Syntax

```
extern __m256i _mm256_insertf128_si256(__m256i a, __m128i b, int offset);
```

Arguments

a	256-bit integer source vector
b	128-bit integer source vector
offset	an integer value that represents the 128-bit offset where the insertion must start

Description

Performs an insertion of 128 bits of packed scalar integer values from the second source vector *b*, into a destination at a 128-bit offset specified by the *offset* parameter. The remaining portions of the destination are written by the corresponding elements of the first source vector *a*.

Returns

Result of the insertion operation.

_mm256_lddqu_si256

Moves unaligned integer from memory. The corresponding Intel® AVX instruction is `VLDDQU`.

Syntax

```
extern __m256i _mm256_lddqu_si256(__m256i const *a);
```

Arguments

**a*	points to a memory location from where unaligned integer value must be moved

Description

Fetches 32 bytes of data, starting at a memory address specified by the *a* parameter, and places them in a destination. This intrinsic calls the corresponding instruction `VLDDQU`, which performs an operation functionally similar to the `VMOVDQU` instruction.

Returns

Result of the move operation.

_mm256_movedup_pd

Duplicates even-indexed double-precision floating point values. The corresponding Intel® AVX instruction is `VMOVDDUP`.

Syntax

```
extern __m256d _mm256_movedup_pd(__m256d a);
```

Arguments

a	float64 source vector

Description

Performs a duplication of even-indexed double-precision floating-point values (float64 values) in the source vector *a*, and returns the result.

Returns

Result of the duplication operation.

_mm256_movehdup_ps

Duplicates odd-indexed single-precision floating point values. The corresponding Intel® AVX instruction is `VMOVSHDUP`.

Syntax

```
extern __m256 _mm256_movehdup_ps(__m256 a);
```

Arguments

a	float32 source vector

Description

Performs a duplication of odd-indexed single-precision floating-point values (float32 values) in the source vector *a*, and returns the result.

Returns

Result of the duplication operation.

_mm256_moveldup_ps

Duplicates even-indexed single-precision floating point values. The corresponding Intel® AVX instruction is `VMOVSLDUP`.

Syntax

```
extern __m256 _mm256_moveldup_ps(__m256 a);
```

Arguments

a	float32 source vector

Description

Performs a duplication of even-indexed single-precision floating-point values (float32 values) in the source vector *a*, and returns the result.

Returns

Result of the duplication operation.

_mm256_movemask_pd

Extracts float64 sign mask. The corresponding Intel® AVX instruction is `VMOVMSKPD`.

Syntax

```
extern int _mm256_movemask_pd(__m256d a);
```

Arguments

a	float64 source vector

Description

Performs an extract operation of sign bits from four double-precision floating point elements (float64 elements) of the source vector *a*, and composes them into bitmasks.

Returns

An integer bitmask of four meaningful bits.

_mm256_movemask_ps

Extracts float32 sign mask. The corresponding Intel® AVX instruction is `VMOVMSKPS`*.*

Syntax

```
extern int _mm256_movemask_ps(__m256 a;
```

Arguments

a	float32 source vector

Description

Performs an extract operation of sign bits from eight single-precision floating point elements (float32 elements) of the source vector *a*, and composes them into bitmasks.

Returns

An integer bitmask of eight meaningful bits.

_mm256_round_pd

Rounds off double-precision floating point values to nearest upper/lower integer depending on rounding mode. The corresponding Intel® AVX instruction is`VROUNDPD`*.*

Syntax

```
extern __m256d _mm256_round_pd(__m256d a, int iRoundMode);
```

Arguments

a	float64 vector
iRoundMode	A hexadecimal value dependent on rounding mode: • For rounding off to upper integer, the value is `0x0A` • For rounding off to lower integer, the value is `0x09`

Description

Rounds off the elements of a float64 vector *a* to the nearest upper/lower integer value. Two shortcuts, in the form of `#defines`, are used to achieve these two separate operations:

```
#define _mm256_ceil_pd(a)    _mm256_round_pd((a), 0x0A)
```

```
#define _mm256_floor_pd(a)   _mm256_round_pd((a), 0x09)
```

These `#defines` tell the preprocessor to replace all instances of `_mm256_ceil_pd(a)` with `_mm256_round_pd((a), 0x0A)` and all instances of `_mm256_floor_pd(a)` with `_mm256_round_pd((a), 0x09)`.

For example, if you write the following:

```
__m256 a, b;
```

```
a = _mm256_ceil_pd(b);
```

the preprocessor will modify it to:

```
a = _mm256_round_pd(b, 0x0a);
```

The Precision Floating Point Exception is signaled according to the (immediate operand) *iRoundMode* value.

Returns

Result of the rounding off operation as a vector with double-precision floating point values.

_mm256_round_ps

Rounds off single-precision floating point values to nearest upper/lower integer depending on rounding mode. The corresponding Intel© AVX instruction is`VROUNDPS`*.*

Syntax

```
extern __m256 _mm256_round_ps(__m256 a, int iRoundMode );
```

Arguments

a	float32 vector
iRoundMode	A hexadecimal value dependent on rounding mode: • For rounding off to upper integer, the value is `0x0A` • For rounding off to lower integer, the value is `0x09`

Description

Rounds off the elements of a float32 vector *a* to the nearest upper/lower integer value. Two shortcuts, in the form of `#defines`, are used to achieve these two separate operations:

```
#define _mm256_ceil_ps(a)    _mm256_round_ps((a), 0x0A)
#define _mm256_floor_ps(a)   _mm256_round_ps((a), 0x09)
```

These `#defines` tells the preprocessor to replace all instances of `_mm256_ceil_ps(a)` with `_mm256_round_ps((a), 0x0A)` and all instances of `_mm256_floor_ps(a)` with `_mm256_round_ps((a), 0x09)`.

For example, if you write the following:

```
__m256 a, b;
a = _mm256_ceil_ps(b);
```

the preprocessor will modify it to:

```
a = _mm256_round_ps(b, 0x0a);
```

The Precision Floating Point Exception is signaled according to the (immediate operand) *iRoundMode* value.

Returns

Result of the rounding off operation as a vector with single-precision floating point values.

_mm256_set_pd

Initializes 256-bit vector with float64 values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256d _mm256_set_pd(double, double, double, double);
```

Arguments

double	a float64 value to be initialized into the 256-bit vector; there are four *double* parameters, one for each float64 vector element

Description

Initializes a 256-bit vector with double-precision floating point values (float64 values) as specified by the *double* parameter.

Returns

A float64 vector initialized with specified double-precision floating point values.

_mm256_set_ps

Initializes 256-bit vector with float32 values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256 _mm256_set_ps(float, float, float, float, float, float, float, float);
```

Arguments

float	a float32 value to be initialized into the 256-bit vector; there are eight *float* parameters, one for each float32 vector element

Description

Initializes a 256-bit vector with single-precision floating point values (float32 values) as specified by the *float* parameter.

Returns

A float32 vector initialized with specified single-precision floating point values.

_mm256_set_epi8/16/32/64x

Initializes 256-bit vector with integer values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256i _mm256_set_epi8(char e31, char e30, char e29, char e28, char e27, char
e26, char e25, char e24, char e23, char e22, char e21, char e20, char e19, char e18,
char e17, char e16, char e15, char e14, char e13, char e12, char e11, char e10, char
e9, char e8, char e7, char e6, char e5, char e4, char e3, char e2, char e1, char e0);
```

```
extern __m256i _mm256_set_epi316(short e15, short e14, short e13, short e12, short e11,
short e10, short e9, short e8, short e7, short e6, short e5, short e4, short e3, short
e2, short e1, short e0);
```

```
extern __m256i _mm256_set_epi32(int e7, int e6, int e5, int e4, int e3, int e2, int e1,
int e0);
```

```
extern __m256i _mm256_set_epi64x(__int64 e3, __int64 e2, __int64 e1, __int64 e0);
```

Arguments

e_n	An 8/16/32/64-bit integer value to be initialized into the 256-bit vector. For each variant, there is one integer parameter for each 8/16/32/64-bit integer vector element.

Description

Initializes a 256-bit vector with extended packed integer values (8/16/32/64-bit values) as specified by the e_n parameter.

Returns

An 8/16/32/64-bit integer vector initialized with specified extended packed integer values.

_mm256_setr_pd

Initializes 256-bit vector with float64 values in reverse of specified order. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256d _mm256_setr_pd(double, double, double, double);
```

Arguments

double	a float64 value to be initialized into the 256-bit vector; there are four *double* parameters, one for each float64 vector element

Description

Initializes a 256-bit vector with double-precision floating point values (float64 values) in reverse order as specified by the *double* parameter.

Returns

A float64 vector initialized with specified double-precision floating point values in reverse.

_mm256_setr_ps

Initializes 256-bit vector with float32 values in reverse of specified order. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256 _mm256_setr_ps(float, float, float, float, float, float, float, float);
```

Arguments

float	a float32 value to be initialized into the 256-bit vector; there are eight *float* parameters, one for each float32 vector element

Description

Initializes a 256-bit vector with single-precision floating point values (float32 values) in reverse order as specified by the *float* parameter.

Returns

A float32 vector initialized with specified single-precision floating point values in reverse.

_mm256_setr_epi32

Initializes 256-bit vector with integer values in reverse of specified order. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256i _mm256_setr_epi32(int, int, int, int, int, int, int, int);
```

```
extern __m256i _mm256_setr_epi8(char e31, char e30, char e29, char e28, char e27, char
e26, char e25, char e24, char e23, char e22, char e21, char e20, char e19, char e18,
char e17, char e16, char e15, char e14, char e13, char e12, char e11, char e10, char
e9, char e8, char e7, char e6, char e5, char e4, char e3, char e2, char e1, char e0);
```

```
extern __m256i _mm256_setr_epi316(short e15, short e14, short e13, short e12, short
e11, short e10, short e9, short e8, short e7, short e6, short e5, short e4, short e3,
short e2, short e1, short e0);
```

```
extern __m256i _mm256_setr_epi32(int e7, int e6, int e5, int e4, int e3, int e2, int
e1, int e0);
```

```
extern __m256i _mm256_setr_epi64x(__int64 e3, __int64 e2, __int64 e1, __int64 e0);
```

Arguments

e_n	An 8/16/32/64-bit integer value to be initialized into the 256-bit vector. For each variant, there is one integer parameter for each 8/16/32/64-bit integer vector element.

Description

Initializes a 256-bit vector with extended packed integer values (8/16/32/64-bit values), in reverse order, as specified by the e_n parameter.

Returns

An 8/16/32/64-bit integer vector initialized with specified extended packed integer values in reverse.

_mm256_set1_pd

Initializes 256-bit vector with scalar double-precision floating point values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256d _mm256_set1_pd(double);
```

Arguments

double	a float64 value to be initialized into the 256-bit vector; there is one *double* parameter to initialize each float64 vector element

Description

Initializes a 256-bit vector with scalar double-precision floating point values (float64 values) as specified by the *double* parameter.

Returns

A float64 vector with all elements set to the specified scalar double-precision floating point value.

_mm256_set1_ps

Initializes 256-bit vector with scalar single-precision floating point values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256 _mm256_set1_ps(float);
```

Arguments

float	a float32 value to be initialized into the 256-bit vector; there is one *float* parameter to initialize each float32 vector element

Description

Initializes a 256-bit vector with scalar single-precision floating point values (float32 values) as specified by the *float* parameter.

Returns

A float32 vector with all elements set to the specified scalar single-precision floating point value.

_mm256_set1_epi32

Initializes 256-bit vector with scalar integer values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256i _mm256_set1_epi8(char a);
```

```
extern __m256i _mm256_set1_epi16(short a);
extern __m256i _mm256_set1_epi32(int a);
extern __m256i _mm256_set1_epi64x(long long a);
```

Arguments

a	An 8/16/32/64-bit integer value to be initialized into the 256-bit vector. For each variant, there is one integer parameter for each 8/16/32/64-bit integer vector element.

Description

Initializes a 256-bit vector with scalar integer values (8/16/32/64-bit values) as specified by the *a* parameter.

Returns

An 8/16/32/64-bit integer vector with all elements set to the specified scalar integer value.

_mm256_setzero_pd

Sets float64 YMM registers to zero. No corresponding Intel© AVX instruction.

Syntax

```
extern __m256d _mm256_setzero_pd(void);
```

Arguments

None

Description

Sets all the elements of a float64 vector to zero and returns the float64 vector. This is a utility intrinsic that helps during programming.

Returns

A float64 vector with all elements set to zero.

_mm256_setzero_ps

Sets float32 YMM registers to zero. No corresponding Intel© AVX instruction.

Syntax

```
extern __m256 _mm256_setzero_ps(void);
```

Arguments

None

Description

Sets all the elements of a float32 vector to zero and returns the float32 vector. This is a utility intrinsic that helps during programming.

Returns

A float32 vector with all elements set to zero.

_mm256_setzero_si256

Sets integer YMM registers to zero. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256i _mm256_setzero_si256(void);
```

Arguments

None

Description

Sets all the elements of an integer vector to zero and returns the integer vector. This is a utility intrinsic that helps during programming.

Returns

An integer vector with all elements set to zero.

_mm256_zeroall

Zeroes all YMM registers. The corresponding Intel® AVX instruction is `VZEROALL`.

Syntax

```
extern void _mm256_zeroall(void);
```

Arguments

None

Description

Zeroes all `YMM` registers. This intrinsic is useful to clear all the YMM registers when transitioning between Intel® Advanced Vector Extensions (Intel® AVX) instructions and legacy Intel® Supplemental SIMD Extensions (Intel® SSE) instructions.

There is no transition penalty if an application clears the bits of all `YMM` registers (sets to '0') via `VZEROALL`, the corresponding instruction for this intrinsic, before transitioning between Intel® Advanced Vector Extensions (Intel® AVX) instructions and legacy Intel® Supplemental SIMD Extensions (Intel® SSE) instructions.

Returns

Nothing

_mm256_zeroupper

Zeroes the upper bits of the YMM registers. The corresponding Intel® AVX instruction is `VZEROUPPER`.

Syntax

```
extern void _mm256_zeroupper(void);
```

Arguments

None

Description

Zeroes the upper 128 bits of all YMM registers. The lower 128 bits that correspond to the XMM registers are left unmodified.

This intrinsic is useful to clear the upper bits of the YMM registers when transitioning between Intel® Advanced Vector Extensions (Intel® AVX) instructions and legacy Intel® Supplemental SIMD Extensions (Intel® SSE) instructions. There is no transition penalty if an application clears the upper bits of all YMM registers (sets to '0') via VZEROUPPER, the corresponding instruction for this intrinsic, before transitioning between Intel® Advanced Vector Extensions (Intel® AVX) instructions and legacy Intel® Supplemental SIMD Extensions (Intel® SSE) instructions.

Returns

Result of the operation.

Intrinsics for Packed Test Operations

_mm256_testz_si256

Performs a packed bit test of two integer vectors to set the ZF flag. The corresponding Intel® AVX instruction is VPTEST*.*

Syntax

```
extern int _mm256_testz_si256(__m256i s1, __m256i s2);
```

Arguments

s1	first source integer vector
s2	second source integer vector

Description

Allows setting of the ZF flag. The ZF flag is set based on the result of a bitwise AND operation between the first and second source vectors. The corresponding instruction VPTEST sets the ZF flag if all the resulting bits are 0. If the resulting bits are non-zeros, the instruction clears the ZF flag.

Returns

Non-zero if ZF flag is set

Zero if the ZF flag is not set

_mm256_testc_si256

Performs a packed bit test of two integer vectors to set the CF flag. The corresponding Intel® AVX instruction is VPTEST*.*

Syntax

```
extern int _mm256_testc_si256(__m256i s1, __m256i s2);
```

Arguments

s1	first source integer vector

s2	second source integer vector

Description

Allows setting of the CF flag. The CF flag is set based on the result of a bitwise AND and logical NOT operation between the first and second source vectors. The corresponding instruction, `VPTEST`, sets the CF flag if all the resulting bits are 0. If the resulting bits are non-zeros, the instruction clears the CF flag.

Returns

Non-zero if CF flag is set

Zero if the CF flag is not set

_mm256_testnzc_si256

Performs a packed bit test of two integer vectors to set ZF and CF flags. The corresponding Intel® AVX instruction is `VPTEST`*.*

Syntax

```
extern int _mm256_testnzc_si256(__m256i s1, __m256i s2);
```

Arguments

s1	first source integer vector
s2	second source integer vector

Description

Performs a packed bit test of *s1* and *s2* vectors using `VTESTPD`*s1*, *s2* instruction and checks the status of the ZF and CF flags. The intrinsic returns 1 if both ZF and CF flags are not 1 (that is, both flags are not set), otherwise returns 0 (that is, one of the flags is set) .

The `VTESTPD` instruction performs a bitwise comparison of all the sign bits of the integer elements in the first source operand and corresponding sign bits in the second source operand. If the AND of the first source operand sign bits with the second source operand sign bits produces all zeros, the ZF flag is set else the ZF flag is clear. If the AND of the inverted first source operand sign bits with the second source operand sign bits produces all zeros the CF flag is set, else the CF flag is clear.

Returns

1: indicates that both ZF and CF flags are clear

0: indicates that either ZF or CF flag is set

_mm256_testz_pd, _mm_testz_pd

Performs a packed bit test of two float64 256-bit or 128-bit vectors to set the ZF flag. The corresponding Intel® AVX instruction is `VTESTPD`*.*

Syntax

```
extern int _mm256_testz_pd(__m256d s1, __m256d s2);

extern int _mm_testz_pd(__m128d s1, __m128d s2);
```

Arguments

s1	first float64 source vector
s2	second float64 source vector

Description

Compute the bitwise AND of the two vectors s1 and s2, representing double-precision (64-bit) floating-point elements, producing an intermediate value, and set ZF to 1 if the sign bit of each 64-bit element in the intermediate value is zero, otherwise set ZF to 0. Compute the bitwise AND NOT of s1 and s2, producing an intermediate value, and set CF to 1 if the sign bit of each 64-bit element in the intermediate value is zero, otherwise set CF to 0. Return the ZF value.

> **NOTE**
> Intel® Advanced Vector Extensions (Intel® AVX) instructions include a full compliment of 128-bit SIMD instructions. Such Intel® AVX instructions, with vector length of 128-bits, zeroes the upper 128 bits of the `YMM` register. The lower 128 bits of the `YMM` register is aliased to the corresponding SIMD `XMM` register.

Returns

Non-zero if ZF flag is set

Zero if the ZF flag is not set

_mm256_testz_ps, _mm_testz_ps

Performs a packed bit test of two float32 256-bit or 128-bit vectors to set the ZF flag. The corresponding Intel® AVX instruction is `VTESTPS`.

Syntax

```
extern int _mm256_testz_ps(__m256 s1, __m256 s2);
```

```
extern int _mm_testz_ps(__m128 s1, __m128 s2);
```

Arguments

s1	first source float32 vector
s2	second source float32 vector

Description

Compute the bitwise AND of the two vectors s1 and s2, representing single-precision (32-bit) floating-point elements, producing an intermediate value, and set ZF to 1 if the sign bit of each 32-bit element in the intermediate value is zero, otherwise set ZF to 0. Compute the bitwise AND NOT of s1 and s2, producing an intermediate value, and set CF to 1 if the sign bit of each 32-bit element in the intermediate value is zero, otherwise set CF to 0. Return the ZF value.

NOTE
Intel® Advanced Vector Extensions (Intel® AVX) instructions include a full compliment of 128-bit SIMD instructions. Such Intel® AVX instructions, with vector length of 128-bits, zeroes the upper 128 bits of the YMM register. The lower 128 bits of the YMM register is aliased to the corresponding SIMD XMM register.

Returns

Non-zero if ZF flag is set

Zero if the ZF flag is not set

_mm256_testc_pd, _mm_testc_pd

Performs a packed bit test of two 256-bit or 128-bit float64 vectors to set the CF flag. The corresponding Intel® AVX instruction is `VTESTPD`.

Syntax

```
extern int _mm256_testc_pd(__m256d s1, __m256d s2);
extern int _mm_testc_pd(__m128d s1, __m128d s2);
```

Arguments

s1	first source float64 vector
s2	second source float64 vector

Description

Compute the bitwise AND of the two vectors s1 and s2, representing double-precision (64-bit) floating-point elements, producing an intermediate value, and set ZF to 1 if the sign bit of each 64-bit element in the intermediate value is zero, otherwise set ZF to 0. Compute the bitwise AND NOT of s1 and s2, producing an intermediate value, and set CF to 1 if the sign bit of each 64-bit element in the intermediate value is zero, otherwise set CF to 0. Return the CF value.

NOTE
Intel® Advanced Vector Extensions (Intel® AVX) instructions include a full compliment of 128-bit SIMD instructions. Such Intel® AVX instructions, with vector length of 128-bits, zeroes the upper 128 bits of the YMM register. The lower 128 bits of the YMM register is aliased to the corresponding SIMD XMM register.

Returns

Non-zero if CF flag is set

Zero if the CF flag is not set

_mm256_testc_ps, _mm_testc_ps

Performs a packed bit test of two 256-bit or 128-bit float32 vectors to set the CF flag. The corresponding Intel® AVX instruction is `VTESTPS`.

Syntax

```
extern int _mm256_testc_ps(__m256 s1, __m256 s2);
extern int _mm_testc_ps(__m128 s1, __m128 s2);
```

Arguments

s1	first source float32 vector
s2	second source float32 vector

Description

Compute the bitwise AND of the two vectors s1 and s2, representing single-precision (32-bit) floating-point elements, producing an intermediate value, and set ZF to 1 if the sign bit of each 32-bit element in the intermediate value is zero, otherwise set ZF to 0. Compute the bitwise AND NOT of s1 and s2, producing an intermediate value, and set CF to 1 if the sign bit of each 32-bit element in the intermediate value is zero, otherwise set CF to 0. Return the ZF value.

> **NOTE**
> Intel® Advanced Vector Extensions (Intel® AVX) instructions include a full compliment of 128-bit SIMD instructions. Such Intel® AVX instructions, with vector length of 128-bits, zeroes the upper 128 bits of the YMM register. The lower 128 bits of the YMM register is aliased to the corresponding SIMD XMM register.

Returns

Non-zero if CF flag is set

Zero if the CF flag is not set

_mm256_testnzc_pd, _mm_testnzc_pd

Performs a packed bit test of two 256-bit float64 or 128-bit float64 vectors to check ZF and CF flag settings. The corresponding Intel® AVX instruction is `VTESTPD`*.*

Syntax

```
extern int _mm256_testnzc_pd(__m256d s1, __m256d s2);
extern int _mm_testnzc_pd(__m128d s1, __m256d s2);
```

Arguments

s1	first source float64 vector
s2	second source float64 vector

Description

Performs a packed bit test of *s1* and *s2* vectors using `VTESTPD`*s1*, *s2* instruction and checks the status of the ZF and CF flags. The intrinsic returns 1 if both ZF and CF flags are not 1 (that is, both flags are not set), otherwise returns 0 (that is, one of the flags is set).

The `VTESTPD` instruction performs a bitwise comparison of all the sign bits of the double-precision elements in the first source operand and corresponding sign bits in the second source operand. If the AND of the first source operand sign bits with the second source operand sign bits produces all zeros, the ZF flag is set else the ZF flag is clear. If the AND of the inverted first source operand sign bits with the second source operand sign bits produces all zeros the CF flag is set, else the CF flag is clear.

The `_mm_testnzc_pd` intrinsic checks the ZF and CF flags according to results of the 128-bit float64 source vectors. The `_m256_testnzc_pd` intrinsic checks the ZF and CF flags according to the results of the 256-bit float64 source vectors.

> **NOTE**
> Intel® Advanced Vector Extensions (Intel® AVX) instructions include a full compliment of 128-bit SIMD instructions. Such Intel® AVX instructions, with vector length of 128-bits, zeroes the upper 128 bits of the YMM register. The lower 128 bits of the YMM register is aliased to the corresponding SIMD XMM register.

Returns

1: indicates that both ZF and CF flags are clear

0: indicates that either ZF or CF flag is set

_mm256_testnzc_ps, _mm_testnzc_ps

Performs a packed bit test of two 256-bit or 128-bit float32 vectors to check ZF and CF flag settings. The corresponding Intel® AVX instruction is `VTESTPS`*.*

Syntax

```
extern int _mm256_testnzc_ps(__m256 s1, __m256 s2);
```

```
extern int _mm_testnzc_ps(__m128 s1, __m128 s2);
```

Arguments

s1	first source float32 vector
s2	second source float32 vector

Description

Performs a packed bit test of *s1* and *s2* vectors using `VTESTPD`*s1*, *s2* instruction and checks the status of the ZF and CF flags. The intrinsic returns 1 if both ZF and CF flags are not 1 (that is, both flags are not set), otherwise returns 0 (that is, one of the flags is set).

The `VTESTPD` instruction performs a bitwise comparison of all the sign bits of the single-precision elements in the first source operand and corresponding sign bits in the second source operand. If the AND of the first source operand sign bits with the second source operand sign bits produces all zeros, the ZF flag is set else the ZF flag is clear. If the AND of the inverted first source operand sign bits with the second source operand sign bits produces all zeros the CF flag is set, else the CF flag is clear.

The `_mm_testnzc_ps` intrinsic checks the ZF and CF flags according to results of the 128-bit float32 source vectors. The `_m256_testnzc_ps` intrinsic checks the ZF and CF flags according to the results of the 256-bit float32 source vectors.

NOTE
Intel® Advanced Vector Extensions (Intel® AVX) instructions include a full compliment of 128-bit SIMD instructions. Such Intel® AVX instructions, with vector length of 128-bits, zeroes the upper 128 bits of the YMM register. The lower 128 bits of the YMM register is aliased to the corresponding SIMD XMM register.

Returns

1: indicates that both ZF and CF flags are clear

0: indicates that either ZF or CF flag is set

Intrinsics for Permute Operations

_mm256_permute_pd, _mm_permute_pd

Permutes 256-bit or 128-bit float64 values into a 256-bit or 128-bit destination vector. The corresponding Intel® AVX instruction is `VPERMILPD`.

Syntax

```
extern __m256d _mm256_permute_pd(__m256d m1, int control);
```

```
extern __m128d _mm_permute_pd(__m128d m1, int control);
```

Arguments

m1	a 256-bit or 128-bit float64 vector
control	an integer specified as an 8-bit immediate; • for the 256-bit *m1* vector this integer contains four 1-bit control fields in the low 4 bits of the immediate • for the 128-bit *m1* vector this integer contains two 1-bit control fields in the low 2 bits of the immediate

Description

The `_mm256_permute_pd` intrinsic permutes double-precision floating point elements (float64 elements) in the 256-bit source vector *m1*, according to a specified 1-bit control field, *control*, and stores the result in a destination vector.

The `_mm_permute_pd` intrinsic permutes double-precision floating point elements (float64 elements) in the 128-bit source vector *m1*, according to a specified 1-bit control field, *control*, and stores the result in a destination vector.

Returns

A 256-bit or 128-bit float64 vector with permuted values.

_mm256_permute_ps, _mm_permute_ps

Permutes 256-bit or 128-bit float32 values into a 256-bit or 128-bit destination vector. The corresponding Intel® AVX instruction is `VPERMILPS`.

Syntax

```
extern __m256 _mm256_permute_ps(__m256 m1, int control);
```

```
extern __m128 _mm_permute_ps(__m128 m1, int control);
```

Arguments

m1	a 256-bit or 128-bit float32 vector
control	an integer specified as an 8-bit immediate; • for the 256-bit *m1* vector this integer contains four 2-bit control fields in the low 8 bits of the immediate • for the 128-bit *m1* vector this integer contains two 2-bit control fields in the low 4 bits of the immediate

Description

The `_mm256_permute_ps` intrinsic permutes single-precision floating point elements (float32 elements) in the 256-bit source vector *m1*, according to a specified 2-bit control field, *control*, and stores the result in a destination vector.

The `_mm_permute_ps` intrinsic permutes single-precision floating point elements (float32 elements) in the 128-bit source vector *m1*, according to a specified 2-bit control field, *control*, and stores the result in a destination vector.

Returns

A 256-bit or 128-bit float32 vector with permuted values.

_mm256_permutevar_pd, _mm_permutevar_pd

Permutes float64 values into a 256-bit or 128-bit destination vector. The corresponding Intel® AVX instruction is `VPERMILPD`.

Syntax

```
extern __m256d _mm256_permutevar_pd(__m256d m1, __m256i control);
```

```
extern __m128d _mm_permutevar_pd(__m128d m1, __m128i control);
```

Arguments

m1	a 256-bit or 128-bit float64 vector
control	a vector with 1-bit control fields, one for each corresponding element of the source vector

- for the 256-bit *m1* source vector this *control* vector contains four 1-bit control fields in the low 4 bits of the immediate
- for the 128-bit *m1* source vector this *control* vector contains two 1-bit control fields in the low 2 bits of the immediate

Description

Permutes double-precision floating-point values in the source vector, *m1*, according to the the 1-bit control fields in the low bytes of corresponding elements of a shuffle control. The result is stored in a destination vector.

Returns

A 256-bit or 128-bit float64 vector with permuted values.

_mm_permutevar_ps, _mm256_permutevar_ps

Permutes float32 values into a 256-bit or 128-bit destination vector. The corresponding Intel® AVX instruction is `VPERMILPS`*.*

Syntax

```
extern __m256 _mm256_permutevar_ps(__m256 m1, __m256i control);
```

```
extern __m128 _mm_permutevar_ps(__m128 m1, __m128i control);
```

Arguments

m1 — a 256-bit or 128-bit float32 vector

control — a vector with 2-bit control fields, one for each corresponding element of the source vector

- for the 256-bit *m1* source vector this *control* vector contains eight 2-bit control fields
- for the 128-bit *m1* source vector this *control* vector contains four 2-bit control fields

Description

Permutes single-precision floating-point values in the source vector, *m1*, according to the the 2-bit control fields in the low bytes of corresponding elements of a shuffle control. The result is stored in a destination vector.

Returns

A 256-bit or 128-bit float32 vector with permuted values.

_mm256_permute2f128_pd

Permutes 128-bit double-precision floating point containing fields into a 256-bit destination vector. The corresponding Intel® AVX instruction is `VPERM2F128`*.*

Syntax

```
extern __m256d _mm256_permute2f128_pd(__m256d m1, __m256d m2, int control);
```

Arguments

m1	a 256-bit float64 source vector
m2	a 256-bit float64 source vector
control	an immediate byte that specifies two 2-bit control fields and two additional bits which specify zeroing behavior.

Description

Permutes 128-bit floating-point-containing fields from the first source vector *m1* and second source vector *m2*, by using bits in the 8-bit *control* argument.

Returns

A 256-bit float64 vector with permuted values.

_mm256_permute2f128_ps

Permutes 128-bit single-precision floating point containing fields into a 256-bit destination vector. The corresponding Intel® AVX instruction is `VPERM2F128`.

Syntax

```
extern __m256 _mm256_permute2f128_ps(__m256 m1, __m256 m2, int control);
```

Arguments

m1	a 256-bit float32 source vector
m2	a 256-bit float32 source vector
control	an immediate byte that specifies two 2-bit control fields and two additional bits which specify zeroing behavior.

Description

Permutes 128-bit floating-point-containing fields from the first source vector *m1* and second source vector *m2*, by using bits in the 8-bit *control* argument.

Returns

A 256-bit float32 vector with permuted values.

_mm256_permute2f128_si256

Permutes 128-bit integer containing fields into a 256-bit destination vector. The corresponding Intel® AVX instruction is `VPERM2F128`.

Syntax

```
extern __m256i _mm256_permute2f128_si256(__m256i m1, __m256i m2, int control);
```

Arguments

m1	a 256-bit integer source vector
m2	a 256-bit integer source vector
control	an immediate byte that specifies two 2-bit control fields and two additional bits which specify zeroing behavior.

Description

Permutes 128-bit integer-containing fields from the first source vector *m1* and second source vector *m2*, by using bits in the 8-bit *control* argument.

Returns

A 256-bit integer vector with permuted values.

Intrinsics for Shuffle Operations

_mm256_shuffle_pd

Shuffles float64 vectors. The corresponding Intel® AVX instruction is `VSHUFPD`*.*

Syntax

```
extern __m256d _mm256_shuffle_pd(__m256d m1, __m256d m2, const int select);
```

Arguments

m1	float64 vector used for the operation
m2	float64 vector also used for the operation
select	a constant of integer type that determines which elements of the source vectors are moved to the result

Description

Moves or shuffles either of the two packed double-precision floating-point elements (float64 elements) from the double quadword in the source vectors to the low and high quadwords of the double quadword of the result.

The elements of the first source vector are moved to the low quadword while the elements of the second source vector are moved to the high quadword of the result. The constant defined by the *select* parameter determines which of the two elements of the source vectors are moved to the result.

Returns

Result of the shuffle operation.

_mm256_shuffle_ps

Shuffles float32 vectors. The corresponding Intel® AVX instruction is `VSHUFPS`*.*

Syntax

```
extern __m256 _mm256_shuffle_ps(__m256 m1, __m256 m2, const int select);
```

Arguments

m1	float32 vector used for the operation
m2	float32 vector also used for the operation
select	a constant of integer type which determines which elements of the source vectors move to the result

Description

Moves or shuffles two of the packed single-precision floating-point elements (float32 elements) from the double quadword in the source vectors to the low and high quadwords of the double quadword of the result.

The elements of the first source vector are moved to the low quadword while the elements of the second source vector are moved to the high quadword of the result. The constant defined by the *select* parameter determines which of the two elements of the source vectors are moved to the result.

Returns

Result of the shuffle operation.

Intrinsics for Unpack and Interleave Operations

_mm256_unpackhi_pd

Unpacks and interleaves high packed double-precision floating point values. The corresponding Intel® AVX instruction is `VUNPCKHPD`*.*

Syntax

```
extern __m256d _mm256_unpackhi_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 source vector
m2	float64 source vector

Description

Performs an interleaved unpack operation of high double-precision floating point values of the two source vectors *m1* and *m2*, and returns the result of the operation.

Returns

A vector with unpacked interleaved double-precision floating point values.

_mm256_unpackhi_ps

Unpacks and interleaves high packed single-precision floating point values. The corresponding Intel® AVX instruction is `VUNPCKHPS`*.*

Syntax

```
extern __m256 _mm256_unpackhi_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 source vector
m2	float32 source vector

Description

Performs an interleaved unpack operation of high single-precision floating point values of the two source vectors *m1* and *m2*, and returns the result of the operation.

Returns

A vector with unpacked interleaved single-precision floating point values.

_mm256_unpacklo_pd

Unpacks and interleaves low packed double-precision floating point values. The corresponding Intel® AVX instruction is `VUNPCKLPD`*.*

Syntax

```
extern __m256d _mm256_unpacklo_pd(__m256d m1, __m256d m2);
```

Arguments

m1	float64 source vector
m2	float64 source vector

Description

Performs an interleaved unpack operation of low double-precision floating point values of the two source vectors *m1* and *m2*, and returns the result of the operation.

Returns

A vector with unpacked interleaved double-precision floating point values.

_mm256_unpacklo_ps

Unpacks and interleaves low packed single-precision floating point values. The corresponding Intel® AVX instruction is `VUNPCKLPS`*.*

Syntax

```
extern __m256 _mm256_unpacklo_ps(__m256 m1, __m256 m2);
```

Arguments

m1	float32 source vector
m2	float32 source vector

Description

Performs an interleaved unpack operation of low single-precision floating point values of the two source vectors *m1* and *m2*, and returns the result of the operation.

Returns

A vector with unpacked interleaved single-precision floating point values.

Support Intrinsics for Vector Typecasting Operations

_mm256_castpd_ps

Typecasts double-precision floating point values to single-precision floating point values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256 _mm256_castpd_ps(__m256d a);
```

Arguments

a	float64 source vector

Description

Performs a typecast operation from double-precision floating point values (float64 values) to single-precision floating point values (float32 values). This intrinsic does not introduce extra moves to the generated code. Source operand bits are passed unchanged to the result.

Returns

A vector with single-precision floating point values.

_mm256_castps_pd

Typecasts single-precision floating point values to double-precision floating point values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256d _mm256_castps_pd(__m256 a);
```

Arguments

a	float32 source vector

Description

Performs a typecast operation from single-precision floating point values (float32 values) to double-precision floating point values (float64 values). This intrinsic does not introduce extra moves to the generated code. Source operand bits are passed unchanged to the result.

Returns

A vector with double-precision floating point values.

_mm256_castpd_si256

Typecasts double-precision floating point values to integer values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256i _mm256_castpd_si256(__m256d a);
```

Arguments

a	float64 source vector

Description

Performs a typecast operation from double-precision floating point values (float64 values) to integer values. This intrinsic does not introduce extra moves to the generated code. Source operand bits are passed unchanged to the result.

Returns

A vector with 256-bit integer values.

_mm256_castps_si256

Typecasts single-precision floating point values to integer values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256i _mm256_castps_si256(__m256 a);
```

Arguments

a	float32 source vector

Description

Performs a typecast operation from single-precision floating point values (float32 values) to integer values. This intrinsic does not introduce extra moves to the generated code. Source operand bits are passed unchanged to the result.

Returns

A vector with 256-bit integer values.

_mm256_castsi256_pd

Typecasts 256-bit integer values to double-precision floating point values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256d _mm256_castsi256_pd(__m256i a);
```

Arguments

a	256-bit integer vector

Description

Performs a typecast operation from 256-bit integer values to double-precision floating point values (float64 values). This intrinsic does not introduce extra moves to the generated code. Source operand bits are passed unchanged to the result.

Returns

A vector with double-precision floating point values.

_mm256_castsi256_ps

Typecasts 256-bit integer values to single-precision floating point values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256 _mm256_castsi256_ps(__m256i a);
```

Arguments

a	256-bit integer source vector

Description

Performs a typecast operation from 256-bit integer values to single-precision floating point values (float32 values). This intrinsic does not introduce extra moves to the generated code. Source operand bits are passed unchanged to the result.

Returns

A vector with single-precision floating point values.

_mm256_castpd128_pd256

Typecasts 128-bit double-precision floating point values to 256-bit double-precision floating point values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256d _mm256_castpd128_pd256(__m128d a);
```

Arguments

a	128-bit float64 vector

Description

Performs a typecast operation from 128-bit double-precision floating point values to 256-bit double-precision floating point values.

The lower 128-bits of the 256-bit resulting vector contains the source vector values; the upper 128-bits of the resulting vector are undefined. This intrinsic does not introduce extra moves to the generated code.

Returns

A vector with 256-bit double-precision floating point values. The upper bits of the resulting vector are undefined.

_mm256_castpd256_pd128

Typecasts 256-bit double-precision floating point values to 128-bit double-precision floating point values. No corresponding Intel© AVX instruction.

Syntax

```
extern __m128d _mm256_castpd256_pd128(__m256d a);
```

Arguments

a	256-bit float64 source vector

Description

Performs a typecast operation from 256-bit double-precision floating point values to 128-bit double-precision floating point values.

The lower 128-bits of the source vector are passed unchanged to the result. This intrinsic does not introduce extra moves to the generated code.

Returns

A vector with 128-bit double-precision floating point values.

_mm256_castps128_ps256

Typecasts 128-bit single-precision floating point values to 256-bit single-precision floating point values. No corresponding Intel© AVX instruction.

Syntax

```
extern __m256 _mm256_castps128_ps256(__m128 a);
```

Arguments

a	128-bit float32 source vector

Description

Performs a typecast operation from 128-bit single-precision floating point values to 256-bit single-precision floating point values.

The lower 128-bits of the 256-bit resulting vector contains the source vector values; the upper 128-bits of the resulting vector are undefined. This intrinsic does not introduce extra moves to the generated code.

Returns

A vector with 256-bit single-precision floating point values. The upper bits of the resulting vector are undefined.

_mm256_castps256_ps128

Typecasts 256-bit single-precision floating point values to 128-bit single-precision floating point values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m128 _mm256_castps256_ps128(__m256 a);
```

Arguments

a	256-bit float32 source vector

Description

Performs a typecast operation from 256-bit single-precision floating point values to 128-bit single-precision floating point values.

The lower 128-bits of the source vector are passed unchanged to the result. This intrinsic does not introduce extra moves to the generated code.

Returns

A vector with 128-bit single-precision floating point values.

_mm256_castsi128_si256

Typecasts 128-bit integer values to 256-bit integer values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256i _mm256_castsi128_si256(__m128i a);
```

Arguments

a	128-bit integer source vector

Description

Performs a typecast operation from 128-bit integer values to 256-bit integer values.

The lower 128-bits of the 256-bit resulting vector contains the source vector values; the upper 128-bits of the resulting vector are undefined. This intrinsic does not introduce extra moves to the generated code.

Returns

A vector with 256-bit integer values. The upper bits of the resulting vector are undefined.

_mm256_castsi256_si128

Typecasts 256-bit integer values to 128-bit integer values. No corresponding Intel® AVX instruction.

Syntax

```
extern __m128i _mm256_castsi256_si128(__m256i a);
```

Arguments

a	256-bit integer source vector

Description

Performs a typecast operation from 256-bit integer values to 128-bit integer values.

The lower 128-bits of the source vector are passed unchanged to the result. This intrinsic does not introduce extra moves to the generated code.

Returns

A vector with 128-bit integer values.

Intrinsics Generating Vectors of Undefined Values

_mm256_undefined_ps()

Returns a vector of eight single precision floating point elements. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256 _mm256_undefined_ps(void);
```

Description

This intrinsic returns a vector of eight single precision floating point elements. The content of the vector is not specified. The prototype of this intrinsic is in the `immintrin.h` header file.

Returns

A vector of eight single precision floating point elements.

See Also

Intrinsics Returning Vectors of Undefined Values

_mm256_undefined_pd()

Returns a vector of four double precision floating point elements. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256d _mm256_undefined_pd(void);
```

Description

This intrinsic returns a vector of four double precision floating point elements. The content of the vector is not specified. The prototype of this intrinsic is in the `immintrin`.h header file.

Returns

A vector of four double precision floating point elements.

See Also

Intrinsics Returning Vectors of Undefined Values

_mm256_undefined_si256

Returns a vector of eight packed doubleword integer elements. No corresponding Intel® AVX instruction.

Syntax

```
extern __m256i _mm256_undefined_si256(void);
```

Description

This intrinsic returns a vector of eight packed doubleword integer elements. The content of the vector is not specified. The prototype of this intrinsic is in the `immintrin.h` header file.

Returns

A vector of eight packed doubleword integer elements.

Intrinsics Returning Vectors of Undefined Values

Intrinsics for Intel® Streaming SIMD Extensions 4 (Intel® SSE4)

The intrinsics in this section correspond to Intel® Streaming SIMD Extensions 4 (Intel® SSE4) instructions.

Efficient Accelerated String and Text Processing

Overview: Efficient Accelerated String and Text Processing

The intrinsics in this section correspond to Intel® Streaming SIMD Extensions 4 (Intel® SSE4) Efficient Accelerated String and Text Processing instructions.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Packed Compare Intrinsics

These Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsics perform packed comparisons. Some of these intrinsics could map to more than one instruction; the Intel® C++ Compiler selects the instruction to generate.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® SSE4 Instruction
`_mm_cmpestri`	Packed comparison, generates index	`PCMPESTRI`
`_mm_cmpestrm`	Packed comparison, generates mask	`PCMPESTRM`

Intrinsic Name	Operation	Corresponding Intel® SSE4 Instruction
`_mm_cmpistri`	Packed comparison, generates index	`PCMPISTRI`
`_mm_cmpistrm`	Packed comparison, generates mask	`PCMPISTRM`
`_mm_cmpestrz`	Packed comparison	`PCMPESTRM` or `PCMPESTRI`
`_mm_cmpestrc`	Packed comparison	`PCMPESTRM` or `PCMPESTRI`
`_mm_cmpestrs`	Packed comparison	`PCMPESTRM` or `PCMPESTRI`
`_mm_cmpestro`	Packed comparison	`PCMPESTRM` or `PCMPESTRI`
`_mm_cmpestra`	Packed comparison	`PCMPESTRM` or `PCMPESTRI`
`_mm_cmpistrz`	Packed comparison	`PCMPISTRM` or`PCMPISTRI`
`_mm_cmpistrc`	Packed comparison	`PCMPISTRM` or `PCMPISTRI`
`_mm_cmpistrs`	Packed comparison	`PCMPISTRM` or `PCMPISTRI`
`_mm_cmpistro`	Packed comparison	`PCMPISTRM` or `PCMPISTRI`
`_mm_cmpistra`	Packed comparison	`PCMPISTRM` or `PCMPISTRI`

_mm_cmpestri

```
int _mm_cmpestri(__m128i src1, int len1, __m128i src2, int len2, const int mode);
```

Performs a packed comparison of string data with explicit lengths, generating an index and storing the result in `ECX`.

_mm_cmpestrm

```
__m128i _mm_cmpestrm(__m128i src1, int len1, __m128i src2, int len2, const int mode);
```

Performs a packed comparison of string data with explicit lengths, generating a mask and storing the result in `XMM0`.

_mm_cmpistri

```
int _mm_cmpistri(__m128i src1, __m128i src2, const int mode);
```

Performs a packed comparison of string data with implicit lengths, generating an index and storing the result in `ECX`.

_mm_cmpistrm

```
__m128i _mm_cmpistrm(__m128i src1, __m128i src2, const int mode);
```

Performs a packed comparison of string data with implicit lengths, generating a mask and storing the result in `XMM0`.

_mm_cmpestrz

`int _mm_cmpestrz(__m128i src1, int len1, __m128i src2, int len2, const int mode);`

Performs a packed comparison of string data with explicit lengths. Returns '1' if `ZFlag == 1`, otherwise '0'.

_mm_cmpestrc

`int _mm_cmpestrc(__m128i src1, int len1, __m128i src2, int len2, const int mode);`

Performs a packed comparison of string data with explicit lengths. Returns '1' if `CFlag == 1`, otherwise '0'.

_mm_cmpestrs

`int _mm_cmpestrs(__m128i src1, int len1, __m128i src2, int len2, const int mode);`

Performs a packed comparison of string data with explicit lengths. Returns '1' if `SFlag == 1`, otherwise '0'.

_mm_cmpestro

`int _mm_cmpestro(__m128i src1, int len1, __m128i src2, int len2, const int mode);`

Performs a packed comparison of string data with explicit lengths. Returns '1' if `OFlag == 1`, otherwise '0'.

_mm_cmpestra

`int _mm_cmpestra(__m128i src1, int len1, __m128i src2, int len2, const int mode);`

Performs a packed comparison of string data with explicit lengths. Returns '1' if `CFlag == 0` and `ZFlag == 0`, otherwise '0'.

_mm_cmpistrz

`int _mm_cmpistrz(__m128i src1, __m128i src2, const int mode);`

Performs a packed comparison of string data with implicit lengths. Returns '1' if `(ZFlag == 1)`, otherwise '0'.

_mm_cmpistrc

`int _mm_cmpistrc(__m128i src1, __m128i src2, const int mode);`

Performs a packed comparison of string data with implicit lengths. Returns '1' if `(CFlag == 1)`, otherwise '0'.

_mm_cmpistrs

`int _mm_cmpistrs(__m128i src1, __m128i src2, const int mode);`

Performs a packed comparison of string data with implicit lengths. Returns '1' if `(SFlag == 1)`, otherwise '0'.

_mm_cmpistro

`int _mm_cmpistro(__m128i src1, __m128i src2, const int mode);`

Performs a packed comparison of string data with implicit lengths. Returns '1' if `(OFlag == 1)`, otherwise '0'.

_mm_cmpistra

`int _mm_cmpistra(__m128i src1, __m128i src2, const int mode);`

Performs a packed comparison of string data with implicit lengths. Returns '1' if `(ZFlag == 0 and CFlag == 0)`, otherwise '0'.

Application Targeted Accelerators Intrinsics

These Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsics extend the capabilities of Intel® architectures by adding performance-optimized, low-latency, lower power fixed-function accelerators on the processor die to benefit specific applications.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsics marked with * are implemented only on Intel® 64 architecture. The rest of the intrinsics are implemented on both IA-32 and Intel® 64 architectures.

Intrinsic Name	Operation	Corresponding Intel® SSE4 Instruction
`_mm_popcnt_u32`	Counts number of set bits in a data operation	`POPCNT`
`_mm_popcnt_u64*`	Counts number of set bits in a data operation	`POPCNT`
`_mm_crc32_u8`	Accumulates cyclic redundancy check	`CRC32`
`_mm_crc32_u16`	Performs cyclic redundancy check	`CRC32`
`_mm_crc32_u32`	Performs cyclic redundancy check	`CRC32`
`_mm_crc32_u64*`	Performs cyclic redundancy check	`CRC32`

_mm_popcnt_u32

`unsigned int _mm_popcnt_u32(unsigned int v);`

Counts the number of set bits in a data operation.

_mm_popcnt_u64

`__int64 _mm_popcnt_u64(unsigned __int64 v);`

Counts the number of set bits in a data operation.

NOTE
Use only on Intel® 64 architecture.

_mm_crc32_u8

`unsigned int _mm_crc32_u8(unsigned int crc, unsigned char v);`

Starting with initial value in the first operand, accumulates CRC32 value for the second operand and stores the result in the destination operand. Accumulates CRC32 on r/m8.

_mm_crc32_u16

```
unsigned int _mm_crc32_u16(unsigned int crc, unsigned short v);
```

Starting with initial value in the first operand, accumulates CRC32 value for the second operand and stores the result in the destination operand. Accumulates CRC32 on r/m16.

_mm_crc32_u32

```
unsigned int _mm_crc32_u32(unsigned int crc, unsigned int v);
```

Starting with initial value in the first operand, accumulates CRC32 value for the second operand and stores the result in the destination operand. Accumulates CRC32 on r/m32.

_mm_crc32_u64

```
unsigned __int64 _mm_crc32_u64(unsigned __int64 crc, unsigned __int64 v);
```

Starting with initial value in the first operand, accumulates CRC32 value for the second operand and stores the result in the destination operand. Accumulates CRC32 on r/m64.

NOTE
Use only on Intel® 64 architecture.

Vectorizing Compiler and Media Accelerators

Overview: Vectorizing Compiler and Media Accelerators

The intrinsics in this section correspond to Intel® Streaming SIMD Extensions 4 (Intel® SSE4) Vectorizing Compiler and Media Accelerators instructions.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Packed Blending Intrinsics

These Intel® Streaming SIMD Extensions 4 (Intel® SSE4) intrinsics pack multiple operations in a single instruction. Blending conditionally copies one field in the source onto the corresponding field in the destination. The prototypes for these intrinsics are in the `smmintrin.h` file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Syntax	Operation	Corresponding Intel® SSE4 Instruction
`__m128 _mm_blend_ps(__m128 v1, __m128 v2, const int mask);`	Selects single precision float data from two sources using constant mask	BLENDPS

Intrinsic Syntax	Operation	Corresponding Intel® SSE4 Instruction
`__m128d _mm_blend_pd(__m128d v1, __m128d v2, const int mask)`	Selects double precision float data from two sources using constant mask	BLENDPD
`__m128 _mm_blendv_ps(__m128 v1, __m128 v2, __m128 v3)`	Selects single precision float data from two sources using variable mask	BLENDVPS
`__m128d _mm_blendv_pd(__m128d v1, __m128d v2, __m128d v3)`	Selects double precision float data from two sources using variable mask	BLENDVPD
`__m128i _mm_blendv_epi8(__m128i v1, __m128i v2, __m128i mask)`	Selects integer bytes from two sources using variable mask	PBLENDVB
`__m128i _mm_blend_epi16(__m128i v1, __m128i v2, const int mask)`	Selects integer words from two sources using constant mask	PBLENDW

Floating Point Dot Product Intrinsics

These Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsics enable floating point single-precision and double-precision dot products. The prototypes for these intrinsics are in the `smmintrin.h` file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic	Operation	Corresponding Intel® SSE4 Instruction
`_mm_dp_pd`	Double-precision dot product	DPPD
`_mm_dp_ps`	Single-precision dot product	DPPS

_mm_dp_pd

```
__m128d _mm_dp_pd( __m128d a, __m128d b, const int mask);
```

Calculates the dot product of double-precision packed values with mask-defined summing and zeroing of the parts of the result.

_mm_dp_ps

```
__m128 _mm_dp_ps( __m128 a, __m128 b, const int mask);
```

Calculates the dot product of single-precision packed values with mask-defined summing and zeroing of the parts of the result.

Packed Format Conversion Intrinsics

These Intel® Streaming SIMD Extensions 4 (Intel® SSE4) intrinsics convert a packed integer to a zero-extended or sign-extended integer with wider type. The prototypes for these intrinsics are in the `smmintrin.h` file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Syntax	Operation	Corresponding Intel® SSE4 Instruction
`__m128i _mm_cvtepi8_epi32(__m128i a)`	Sign extend four bytes into four doublewords	`PMOVSXBD`
`__m128i _mm_cvtepi8_epi64 (__m128i a)`	Sign extend two bytes into two quadwords	`PMOVSXBQ`
`__m128i _mm_cvtepi8_epi16(__m128i a)`	Sign extend eight bytes into eight words	`PMOVSXBW`
`__m128i _mm_cvtepi32_epi64(__m128i a)`	Sign extend two doublewords into two quadwords	`PMOVSXDQ`
`__m128i _mm_cvtepi16_epi32(__m128i a)`	Sign extend four words into four doublewords	`PMOVSXWD`
`__m128i _mm_cvtepi16_epi64(__m128i a)`	Sign extend two words into two quadwords	`PMOVSXWQ`
`__m128i _mm_cvtepu8_epi32(__m128i a)`	Zero extend four bytes into four doublewords	`PMOVZXBD`
`__m128i _mm_cvtepu8_epi64(__m128i a)`	Zero extend two bytes into two quadwords	`PMOVZXBQ`
`__m128i _mm_cvtepu8_epi16(__m128i a)`	Zero extend eight bytes into eight words	`PMOVZXBW`
`__m128i _mm_cvtepu32_epi64(__m128i a)`	Zero extend two doublewords into two quadwords	`PMOVZXDQ`
`__m128i _mm_cvtepu16_epi32(__m128i a)`	Zero extend four words into four doublewords	`PMOVZXWD`
`__m128i _mm_cvtepu16_epi64(__m128i a)`	Zero extend two words into two quadwords	`PMOVZXWQ`

Packed Integer Min/Max Intrinsics

These Intel® Streaming SIMD Extensions 4 (Intel® SSE4) intrinsics compare packed integers in the destination operand and the source operand, and return the minimum or maximum for each packed operand in the destination operand. The prototypes for these intrinsics are in the `smmintrin.h` file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Syntax	Operation	Corresponding Intel® SSE4 Instruction
`__m128i _mm_max_epi8( __m128i a, __m128i b)`	Calculates maximum of signed packed integer bytes	`PMAXSB`
`__m128i _mm_max_epi32( __m128i a, __m128i b)`	Calculates maximum of signed packed integer doublewords	`PMAXSD`
`__m128i _mm_max_epu32( __m128i a, __m128i b)`	Calculates maximum of unsigned packed integer doublewords	`PMAXUD`
`__m128i _mm_max_epu16( __m128i a, __m128i b)`	Calculates maximum of unsigned packed integer words	`PMAXUW`
`__m128i _mm_min_epi8( __m128i a, __m128i b)`	Calculates minimum of signed packed integer bytes	`PMINSB`
`__m128i _mm_min_epi32( __m128i a, __m128i b)`	Calculates minimum of signed packed integer doublewords	`PMINSD`
`__m128i _mm_min_epu32( __m128i a, __m128i b)`	Calculates minimum of unsigned packed integer double words	`PMINUD`
`__m128i _mm_min_epu16( __m128i a, __m128i b)`	Calculates minimum of unsigned packed integer words	`PMINUW`

Floating Point Rounding Intrinsics

These Intel® Streaming SIMD Extensions 4 (Intel® SSE4) rounding intrinsics cover scalar and packed single-precision and double-precision floating-point operands. The prototypes for these intrinsics are in the `smmintrin.h` file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The `floor` and `ceil` intrinsics correspond to the definitions of `floor` and `ceil` in the ISO 9899:1999 standard for the C programming language.

Intrinsic Syntax	Operation	Corresponding Intel® SSE4 Instruction

`__m128d _mm_round_pd(__m128d s1, int iRoundMode)`
`__m128d _mm_floor_pd(__m128d s1)`
`__m128d _mm_ceil_pd(__m128d s1)`
	Packed double-precision float rounding	`ROUNDPD`

Intrinsic Syntax	Operation	Corresponding Intel® SSE4 Instruction

`__m128 _mm_round_ps(__m128 s1, int iRoundMode)`
`__m128 _mm_floor_ps(__m128 s1)`
`__m128 _mm_ceil_ps(__m128 s1)`
	Packed single-precision float rounding	`ROUNDPS`

`__m128d _mm_round_sd(__m128d dst, __m128d s1, int iRoundMode)`
`__m128d _mm_floor_sd(__m128d dst, __m128d s1)`
`__m128d _mm_ceil_sd(__m128d dst, __m128d s1)`
	Single double-precision float rounding	`ROUNDSD`

`__m128 _mm_round_ss(__m128 dst, __m128d s1, int iRoundMode)`
`__m128 _mm_floor_ss(__m128d dst, __m128 s1)`
`__m128 _mm_ceil_ss(__m128d dst, __m128 s1)`
	Single single-precision float rounding	`ROUNDSS`

DWORD Multiply Intrinsics

These Intel® Streaming SIMD Extensions (Intel® SSE4) DWORD multiply intrinsics are designed to aid vectorization. They enable four simultaneous 32-bit by 32-bit multiplies. The prototypes for these intrinsics are in the `smmintrin.h` file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Syntax	Operation	Corresponding Intel® SSE4 Instruction
`__m128i _mm_mul_epi32( __m128i a, __m128i b)`	Packed integer 32-bit multiplication of two low pairs of operands producing two 64-bit results	`PMULDQ`
`__m128i _mm_mullo_epi32( __m128i a, __m128i b)`	Packed integer 32-bit multiplication with truncation of upper halves of results	`PMULLD`

Register Insertion/Extraction Intrinsics

These Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsics enable data insertion and extraction between general purpose registers and `XMM` registers. The prototypes for these intrinsics are in the `smmintrin.h` file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsics marked with * are implemented only on Intel® 64 architectures. The rest of the intrinsics are implemented on both IA-32 and Intel® 64 architectures.

Intrinsic Syntax	Operation	Corresponding Intel® SSE4 Instruction
`__m128 _mm_insert_ps(__m128 dst, __m128 src, const int ndx)`	Insert single precision float into packed single precision array element selected by index.	`INSERTPS`
`int _mm_extract_ps(__m128 src, const int ndx)`	Extract single precision float from packed single precision array element selected by index.	`EXTRACTPS`
`__m128i _mm_insert_epi8(__m128i s1, int s2, const int ndx)`	Insert integer byte into packed integer array element selected by index.	`PINSRB`
`int _mm_extract_epi8(__m128i src, const int ndx)`	Extract integer byte from packed integer array element selected by index.	`PEXTRB`
`int _mm_extract_epi16(__m128i src, int ndx)`	Extract integer word from packed integer array element selected by index.	`PEXTRW`
`__m128i _mm_insert_epi32(__m128i s1, int s2, const int ndx)`	Insert integer doubleword into packed integer array element selected by index.	`PINSRD`
`int _mm_extract_epi32(__m128i src, const int ndx)`	Extract integer doubleword from packed integer array element selected by index.	`PEXTRD`
`__m128i _mm_insert_epi64(__m128i s2, int s, const int ndx)`	Insert integer quadword into packed integer array element selected by index. Use only on Intel® 64 architectures.	`PINSRQ`
`__int64 _mm_extract_epi64(__m128i src, const int ndx)`	Extract integer quad word from packed integer array element selected by index. Use only on Intel® 64 architectures.	`PEXTRQ`

Test Intrinsics

These Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsics perform packed integer 128-bit comparisons. The prototypes for these intrinsics are in the `smmintrin.h` file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® SSE4 Instruction
`_mm_testz_si128`	Checks for all zeros in specified bits of a 128-bit value	`PTEST`
`_mm_testc_si128`	Checks for all ones in specified bits of a 128-bit value	`PTEST`

Intrinsic Name	Operation	Corresponding Intel® SSE4 Instruction
`_mm_testnzc_si128`	Checks for at least one '0' and at least one '1' in the specified bits of a 128-bit value	`PTEST`

_mm_testz_si128

```
int _mm_testz_si128(__m128i s1, __m128i s2);
```

Returns '1' if the bitwise AND operation on `s1` and `s2` results in all zeros, else returns '0'. That is,

```
_mm_testz_si128 := ( (s1 & s2) == 0 ? 1 : 0 )
```

This intrinsic checks if the `ZF` flag equals '1' as a result of the instruction `PTEST` *`s1`*, *`s2`*. For example, it allows you to check if all set bits in *s2* (mask) are zeros in *s1*.

Corresponding instruction: `PTEST`

_mm_testc_si128

```
int _mm_testc_si128(__m128i s1, __m128i s2);
```

Returns '1' if the bitwise AND operation on *s2* and logical NOT *s1* results in all zeros, else returns '0'. That is,

```
_mm_testc_si128 := ( (~s1 & s2) == 0 ? 1 : 0 )
```

This intrinsic checks if the `CF` flag equals '1' as a result of the instruction `PTEST` *`s1`*, *`s2`*. For example it allows you to check if all set bits in *s2* (mask) are also set in *s1*.

Corresponding instruction: `PTEST`

_mm_testnzc_si128

```
int _mm_testnzc_si128(__m128i s1, __m128i s2);
```

Returns '1' if the following conditions are true: bitwise operation of *s1* AND *s2* does not equal all zeros and bitwise operation of NOT *s1* AND *s2* does not equal all zeros, otherwise returns '0'. That is,

```
_mm_testnzc_si128 := ( ( (s1 & s2) != 0 && (~s1 & s2) != 0 ) ? 1 : 0 )
```

This intrinsic checks if both the `CF` and `ZF` flags are not '1' as a result of the instruction `PTEST` *`s1`*, *`s2`*. For example, it allows you to check that the result has both zeros and ones in *s1* on positions specified as set bits in *s2* (mask).

Corresponding instruction: `PTEST`

Packed DWORD to Unsigned WORD Intrinsic

The prototype for this Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsic is in the `smmintrin.h` file.

To use this intrinsic, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

_mm_packus_epi32

```
__m128i _mm_packus_epi32(__m128i m1, __m128i m2);
```

Converts eight packed signed doublewords into eight packed unsigned words, using unsigned saturation to handle overflow condition.

Corresponding instruction: `PACKUSDW`

Packed Compare for Equal Intrinsic

The prototype for this Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsic is in the `smmintrin.h` file.

To use this intrinsic, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

_mm_cmpeq_epi64

```
__m128i _mm_cmpeq_epi64(__m128i a, __m128i b);
```

Performs a packed integer 64-bit comparison for equality. The intrinsic fills the corresponding parts of the result with zeroes or ones based on equality.

Corresponding instruction: `PCMPEQQ`

Cacheability Support Intrinsic

The prototype for this Intel® Streaming SIMD Extensions (Intel® SSE4) intrinsic is in the `smmintrin.h` file.

To use this intrinsic, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

_mm_stream_load_si128

```
extern __m128i _mm_stream_load_si128(__m128i* v1);
```

Loads `__m128` data from a 16-byte aligned address, *v1*, to the destination operand, `m128i` without polluting the caches.

Corresponding instruction: `MOVNTDQA`

Intrinsics for Intel® Supplemental Streaming SIMD Extensions 3 (SSSE3)

Intel® C++ intrinsics listed in this section correspond to the Supplemental Streaming SIMD Extensions 3 (SSSE3) instructions. The prototypes for these intrinsics are in `tmmintrin.h`.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The topics in this section summarize these intrinsics.

Addition Intrinsics

These Supplemental Streaming SIMD Extensions 3 (SSSE3) intrinsics are used for horizontal addition. The prototypes for these intrinsics are in `tmmintrin.h`.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

_mm_hadd_epi16

```
extern __m128i _mm_hadd_epi16(__m128i a, __m128i b);
```

Adds horizontally packed signed words. Interpreting *a*, *b*, and *r* as arrays of 16-bit signed integers:

```
for (i = 0; i < 4; i++) {
r[i] = a[2*i] + a[2i+1];
r[i+4] = b[2*i] + b[2*i+1];
}
```

_mm_hadd_epi32

`extern __m128i _mm_hadd_epi32(__m128i a, __m128i b);`

Adds horizontally packed signed doublewords. Interpreting *a*, *b*, and *r* as arrays of 32-bit signed integers:

```
for (i = 0; i < 2; i++) {
r[i] = a[2*i] + a[2i+1];
r[i+2] = b[2*i] + b[2*i+1];
}
```

_mm_hadds_epi16

`extern __m128i _mm_hadds_epi16(__m128i a, __m128i b);`

Adds horizontally packed signed words with signed saturation. Interpreting *a*, *b*, and *r* as arrays of 16-bit signed integers:

```
for (i = 0; i < 4; i++) {
r[i] = signed_saturate_to_word(a[2*i] + a[2i+1]);
r[i+4] = signed_saturate_to_word(b[2*i] + b[2*i+1]);
}
```

_mm_hadd_pi16

`extern __m64 _mm_hadd_pi16(__m64 a, __m64 b);`

Adds horizontally packed signed words. Interpreting *a*, *b*, and *r* as arrays of 16-bit signed integers:

```
for (i = 0; i < 2; i++) {
r[i] = a[2*i] + a[2i+1];
r[i+2] = b[2*i] + b[2*i+1];
}
```

_mm_hadd_pi32

`extern __m64 _mm_hadd_pi32(__m64 a, __m64 b);`

Adds horizontally packed signed doublewords. Interpreting *a*, *b*, and *r* as arrays of 32-bit signed integers:

```
r[0] = a[1] + a[0];
r[1] = b[1] + b[0];
```

_mm_hadds_pi16

`extern __m64 _mm_hadds_pi16(__m64 a, __m64 b);`

Adds horizontally packed signed words with signed saturation. Interpreting *a*, *b*, and *r* as arrays of 16-bit signed integers:

```
for (i = 0; i < 2; i++) {
r[i] = signed_saturate_to_word(a[2*i] + a[2i+1]);
r[i+2] = signed_saturate_to_word(b[2*i] + b[2*i+1]);
}
```

Subtraction Intrinsics

These Supplemental Streaming SIMD Extensions 3 (SSSE3) intrinsics are used for horizontal subtraction. The prototypes for these intrinsics are in `tmmintrin.h`.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

_mm_hsub_epi16

`extern __m128i _mm_hsub_epi16(__m128i a, __m128i b);`

Subtract horizontally packed signed words.

Interpreting *a*, *b*, and *r* as arrays of 16-bit signed integers:

```
for (i = 0; i < 4; i++) {
r[i] = a[2*i] - a[2i+1];
r[i+4] = b[2*i] - b[2*i+1];
}
```

_mm_hsub_epi32

`extern __m128i _mm_hsub_epi32(__m128i a, __m128i b);`

Subtracts horizontally packed signed doublewords.

Interpreting *a*, *b*, and *r* as arrays of 32-bit signed integers:

```
for (i = 0; i < 2; i++) {
r[i] = a[2*i] - a[2i+1];
r[i+2] = b[2*i] - b[2*i+1];
}
```

_mm_hsubs_epi16

`extern __m128i _mm_hsubs_epi16(__m128i a, __m128i b);`

Subtracts horizontally packed signed words with signed saturation.

Interpreting *a*, *b*, and *r* as arrays of 16-bit signed integers:

```
for (i = 0; i < 4; i++) {
r[i] = signed_saturate_to_word(a[2*i] - a[2i+1]);
r[i+4] = signed_saturate_to_word(b[2*i] - b[2*i+1]);
}
```

_mm_hsub_pi16

`extern __m64 _mm_hsub_pi16(__m64 a, __m64 b);`

Subtracts horizontally packed signed words.

Interpreting *a*, *b*, and *r* as arrays of 16-bit signed integers:

```
for (i = 0; i < 2; i++) {
r[i] = a[2*i] - a[2i+1];
r[i+2] = b[2*i] - b[2*i+1];
}
```

_mm_hsub_pi32

```
extern __m64 _mm_hsub_pi32(__m64 a, __m64 b);
```

Subtracts horizontally packed signed doublewords.

Interpreting *a*, *b*, and *r* as arrays of 32-bit signed integers:

```
r[0] = a[0] - a[1];
r[1] = b[0] - b[1];
```

_mm_hsubs_pi16

```
extern __m64 _mm_hsubs_pi16(__m64 a, __m64 b);
```

Subtracts horizontally packed signed words with signed saturation.

Interpreting *a*, *b*, and *r* as arrays of 16-bit signed integers:

```
for (i = 0; i < 2; i++) {
r[i] = signed_saturate_to_word(a[2*i] - a[2i+1]);
r[i+2] = signed_saturate_to_word(b[2*i] - b[2*i+1]);
}
```

Multiplication Intrinsics

These Supplemental Streaming SIMD Extensions 3 (SSSE3) intrinsics are used for multiplication. The prototypes for these intrinsics are in `tmmintrin.h`.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

_mm_maddubs_epi16

```
extern __m128i _mm_maddubs_epi16(__m128i a, __m128i b);
```

Multiplies signed and unsigned bytes, adds horizontal pair of signed words, and packs saturated signed words.

Interpreting *a* as array of unsigned 8-bit integers, *b* as arrays of signed 8-bit integers, and *r* as arrays of 16-bit signed integers:

```
for (i = 0; i < 8; i++) {
r[i] = signed_saturate_to_word(a[2*i+1] * b[2*i+1] + a[2*i]*b[2*i]);
}
```

_mm_maddubs_pi16

```
extern __m64 _mm_maddubs_pi16(__m64 a, __m64 b);
```

Multiplies signed and unsigned bytes, adds horizontal pair of signed words, and packs saturated signed words.

Interpreting *a* as array of unsigned 8-bit integers, *b* as arrays of signed 8-bit integers, and *r* as arrays of 16-bit signed integers:

```
for (i = 0; i < 4; i++) {
r[i] = signed_saturate_to_word(a[2*i+1] * b[2*i+1] + a[2*i]*b[2*i]);
}
```

_mm_mulhrs_epi16

`extern __m128i _mm_mulhrs_epi16(__m128i a, __m128i b);`

Multiplies signed words, scales and rounds signed doublewords, and packs high 16-bits.

Interpreting *a*, *b*, and *r* as arrays of signed 16-bit integers:

```
for (i = 0; i < 8; i++) {
r[i] =  (( (int32)((a[i] * b[i]) >> 14) + 1) >> 1) & 0xFFFF;
}
```

_mm_mulhrs_pi16

`extern __m64 _mm_mulhrs_pi16(__m64 a, __m64 b);`

Multiplies signed words, scales and rounds signed doublewords, and packs high 16-bits.

Interpreting *a*, *b*, and *r* as arrays of signed 16-bit integers:

```
for (i = 0; i < 4; i++) {
r[i] =  (( (int32)((a[i] * b[i]) >> 14) + 1) >> 1) & 0xFFFF;
}
```

Absolute Value Intrinsics

These Supplemental Streaming SIMD Extensions 3 (SSSE3) intrinsics are used to compute absolute values. The prototypes for these intrinsics are in `tmmintrin.h`.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

_mm_abs_epi8

`extern __m128i _mm_abs_epi8(__m128i a);`

Computes absolute value of signed bytes. Interpreting *a* and *r* as arrays of signed 8-bit integers:

```
for (i = 0; i < 16; i++) {
r[i] = abs(a[i]);
}
```

_mm_abs_epi16

`extern __m128i _mm_abs_epi16(__m128i a);`

Computes absolute value of signed words. Interpreting *a* and *r* as arrays of signed 16-bit integers:

```
for (i = 0; i < 8; i++) {
r[i] = abs(a[i]);
}
```

_mm_abs_epi32

`extern __m128i _mm_abs_epi32(__m128i a);`

Computes absolute value of signed doublewords. Interpreting *a* and *r* as arrays of signed 32-bit integers:

```
for (i = 0; i < 4; i++) {
r[i] = abs(a[i]);
}
```

_mm_abs_pi8

`extern __m64 _mm_abs_pi8(__m64 a);`

Computes absolute value of signed bytes. Interpreting *a* and *r* as arrays of signed 8-bit integers:

```
for (i = 0; i < 8; i++) {
r[i] = abs(a[i]);
}
```

_mm_abs_pi16

`extern __m64 _mm_abs_pi16(__m64 a);`

Computes absolute value of signed words. Interpreting *a* and *r* as arrays of signed 16-bit integers:

```
for (i = 0; i < 4; i++) {
r[i] = abs(a[i]);
}
```

_mm_abs_pi32

`extern __m64 _mm_abs_pi32(__m64 a);`

Computes absolute value of signed doublewords. Interpreting *a* and *r* as arrays of signed 32-bit integers:

```
for (i = 0; i < 2; i++) {
r[i] = abs(a[i]);
}
```

Shuffle Intrinsics

These Supplemental Streaming SIMD Extensions 3 (SSSE3) intrinsics are used to perform shuffle operations. The prototypes for these intrinsics are in `tmmintrin.h`.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

_mm_shuffle_epi8

`extern __m128i _mm_shuffle_epi8(__m128i a, __m128i b);`

Shuffle bytes from *a* according to contents of *b*.

Interpreting *a*, *b*, and *r* as arrays of unsigned 8-bit integers:

```
for (i = 0; i < 16; i++){
 if (b[i] & 0x80){
  r[i] =  0;
 }
 else {
  r[i] = a[b[i] & 0x0F];
 }
}
```

_mm_shuffle_pi8

`extern __m64 _mm_shuffle_pi8(__m64 a, __m64 b);`

Shuffle bytes from *a* according to contents of *b*.

Interpreting *a*, *b*, and *r* as arrays of unsigned 8-bit integers:

```
for (i = 0; i < 8; i++){
 if (b[i] & 0x80){
  r[i] =  0;
 }
else {
 r[i] = a[b[i] & 0x07];
 }
}
```

Concatenate Intrinsics

These Supplemental Streaming SIMD Extensions 3 (SSSE3) intrinsics are used concatenation. The prototypes for these intrinsics are in `tmmintrin.h`.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

_mm_alignr_epi8

`extern __m128i _mm_alignr_epi8(__m128i a, __m128i b, int n);`

Concatenates *a* and *b*, extracts byte-aligned result shifted to the right by *n*.

Interpreting `t1` as 256-bit unsigned integer, *a*, *b*, and *r* as 128-bit unsigned integers:

```
t1[255:128] = a;
t1[127:0] = b;
t1[255:0] = t1[255:0] >> (8 * n); // unsigned shift
r[127:0] = t1[127:0];
```

_mm_alignr_pi8

`extern __m64 _mm_alignr_pi8(__m64 a, __m64 b, int n);`

Concatenates *a* and *b*, extracts byte-aligned result shifted to the right by *n*.

Interpreting `t1` as 128-bit unsigned integer, *a*, *b*, and *r* as 64-bit unsigned integers:

```
t1[127:64] = a;
t1[63:0] = b;
t1[127:0] = t1[127:0] >> (8 * n); // unsigned shift
r[63:0] = t1[63:0];
```

Negation Intrinsics

These Supplemental Streaming SIMD Extensions 3 (SSSE3) intrinsics are used for negation. The prototypes for these intrinsics are in `tmmintrin.h`.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

_mm_sign_epi8

`extern __m128i _mm_sign_epi8(__m128i a, __m128i b);`

Negates packed bytes in *a* if corresponding sign in *b* is less than zero.

Interpreting *a*, *b*, and *r* as arrays of signed 8-bit integers:

```
for (i = 0; i < 16; i++){
 if (b[i] < 0){
  r[i] =  -a[i];
 }
 else
 if (b[i] == 0){
  r[i] = 0;
 }
 else {
  r[i] = a[i];
 }
}
```

_mm_sign_epi16

`extern __m128i _mm_sign_epi16(__m128i a, __m128i b);`

Negates packed words in *a* if corresponding sign in *b* is less than zero.

Interpreting *a*, *b*, and *r* as arrays of signed 16-bit integers:

```
for (i = 0; i < 8; i++){
 if (b[i] < 0){
  r[i] =  -a[i];
 }
else
 if (b[i] == 0){
  r[i] = 0;
 }
 else
 {
  r[i] = a[i];
 }
}
```

_mm_sign_epi32

`extern __m128i _mm_sign_epi32(__m128i a, __m128i b);`

Negates packed doublewords in *a* if corresponding sign in *b* is less than zero.

Interpreting *a*, *b*, and *r* as arrays of signed 32-bit integers:

```
for (i = 0; i < 4; i++){
 if (b[i] < 0){
  r[i] = -a[i];
 }
 else
 if (b[i] == 0){
  r[i] = 0;
 }
 else {
  r[i] = a[i];
 }
}
```

_mm_sign_pi8

```
extern __m64 _mm_sign_pi8(__m64 a, __m64 b);
```

Negates packed bytes in *a* if corresponding sign in *b* is less than zero.

Interpreting *a*, *b*, and *r* as arrays of signed 8-bit integers:

```
for (i = 0; i < 16; i++){
 if (b[i] < 0){
  r[i] =  -a[i];
 }
 else
 if (b[i] == 0){
  r[i] = 0;
 }
 else {
  r[i] = a[i];
 }
}
```

_mm_sign_pi16

```
extern __m64 _mm_sign_pi16(__m64 a, __m64 b);
```

Negates packed words in *a* if corresponding sign in *b* is less than zero.

Interpreting *a*, *b*, and *r* as arrays of signed 16-bit integers:

```
for (i = 0; i < 8; i++){
 if (b[i] < 0){
  r[i] =  -a[i];
  }
 else
 if (b[i] == 0){
  r[i] = 0;
  }
 else {
  r[i] = a[i];
  }
}
```

_mm_sign_pi32

```
extern __m64 _mm_sign_pi32(__m64 a, __m64 b);
```

Negates packed doublewords in *a* if corresponding sign in *b* is less than zero.

Interpreting *a*, *b*, and *r* as arrays of signed 32-bit integers:

```
for (i = 0; i < 2; i++){
 if (b[i] < 0){
  r[i] =  -a[i];
 }
 else
 if (b[i] == 0){
  r[i] = 0;
 }
 else {
  r[i] = a[i];
 }
}
```

Intrinsics for Intel® Streaming SIMD Extensions 3 (Intel® SSE3)

The Intel® C++ intrinsics listed in this section are designed for the Intel® Pentium® 4 processor with Streaming SIMD Extensions 3 (Intel® SSE3). The prototypes for these intrinsics are in the `pmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The topics in this section summarize these intrinsics.

Integer Vector Intrinsic

The integer vector intrinsic listed here is designed for the Intel® Pentium® 4 processor with Streaming SIMD Extensions 3 (Intel® SSE3). The prototype for this intrinsic is in the `pmmintrin.h` header file.

To use this intrinsic, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

`R` represents the register into which the returns are placed.

_mm_lddqu_si128

`__m128i _mm_lddqu_si128(__m128i const *p);`

Loads an unaligned 128-bit value. This differs from `MOVDQU` in that it can provide higher performance in some cases. However, it also may provide lower performance than `MOVDQU` if the memory value being read was just written.

R
`*p;`

Single-precision Floating-point Vector Intrinsics

The single-precision floating-point vector intrinsics listed here are designed for the Intel® Pentium® 4 processor with Streaming SIMD Extensions 3 (Intel® SSE3). The prototypes for these intrinsics are in the `pmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in the registers `R0`, `R1`, `R2`, and `R3`.

Intrinsic Name	Operation	Corresponding Intel® SSE3 Instruction
`_mm_addsub_ps`	Subtract and add	`ADDSUBPS`
`_mm_hadd_ps`	Add	`HADDPS`
`_mm_hsub_ps`	Subtracts	`HSUBPS`
`_mm_movehdup_ps`	Duplicates	`MOVSHDUP`

Intrinsic Name	Operation	Corresponding Intel® SSE3 Instruction
`_mm_moveldup_ps`	Duplicates	`MOVSLDUP`

_mm_addsub_ps

```
extern __m128 _mm_addsub_ps(__m128 a, __m128 b);
```

Subtracts even vector elements while adding odd vector elements.

R0	R1	R2	R3
`a0 - b0;`	`a1 + b1;`	`a2 - b2;`	`a3 + b3;`

_mm_hadd_ps

```
extern __m128 _mm_hadd_ps(__m128 a, __m128 b);
```

Adds adjacent vector elements.

R0	R1	R2	R3
`a0 + a1;`	`a2 + a3;`	`b0 + b1;`	`b2 + b3;`

_mm_hsub_ps

```
extern __m128 _mm_hsub_ps(__m128 a, __m128 b);
```

Subtracts adjacent vector elements.

R0	R1	R2	R3
`a0 - a1;`	`a2 - a3;`	`b0 - b1;`	`b2 - b3;`

_mm_movehdup_ps

```
extern __m128 _mm_movehdup_ps(__m128 a);
```

Duplicates odd vector elements into even vector elements.

R0	R1	R2	R3
`a1;`	`a1;`	`a3;`	`a3;`

_mm_moveldup_ps

```
extern __m128 _mm_moveldup_ps(__m128 a);
```

Duplicates even vector elements into odd vector elements.

R0	R1	R2	R3
`a0;`	`a0;`	`a2;`	`a2;`

Double-precision Floating-point Vector Intrinsics

The double-precision floating-point intrinsics listed here are designed for the Intel® Pentium® 4 processor with Streaming SIMD Extensions 3 (Intel® SSE3). The prototypes for these intrinsics are in the `pmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in the registers `R0` and `R1`.

Intrinsic Name	Operation	Corresponding Intel® SSE3 Instruction
`_mm_addsub_pd`	Subtract and add	`ADDSUBPD`
`_mm_hadd_pd`	Add	`HADDPD`
`_mm_hsub_pd`	Subtract	`HSUBPD`
`_mm_loaddup_pd`	Duplicate	`MOVDDUP`
`_mm_movedup_pd`	Duplicate	`MOVDDUP`

_mm_addsub_pd

```
extern __m128d _mm_addsub_pd(__m128d a, __m128d b);
```

Adds upper vector element while subtracting lower vector element.

R0	R1
`a0 - b0;`	`a1 + b1;`

_mm_hadd_pd

```
extern __m128d _mm_hadd_pd(__m128d a, __m128d b);
```

Adds adjacent vector elements.

R0	R1
`a0 + a1;`	`b0 + b1;`

_mm_hsub_pd

```
extern __m128d _mm_hsub_pd(__m128d a, __m128d b);
```

Subtracts adjacent vector elements.

R0	R1
`a0 - a1;`	`b0 - b1;`

_mm_loaddup_pd

```
extern __m128d _mm_loaddup_pd(double const * dp);
```

Duplicates a double value into upper and lower vector elements.

R0	R1
`*dp;`	`*dp;`

_mm_movedup_pd

```
extern __m128d _mm_movedup_pd(__m128d a);
```

Duplicates lower vector element into upper vector element.

R0	R1
`a0;`	`a0;`

Miscellaneous Intrinsics

The intrinsics listed here are designed for the Intel® Pentium® 4 processor with Streaming SIMD Extensions 3 (Intel® SSE3). The prototypes for these intrinsics are in the `pmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

_mm_monitor

```
extern void _mm_monitor(void const *p, unsigned extensions, unsigned hints);
```

Generates the `MONITOR` instruction. This sets up an address range for the monitor hardware using *p* to provide the logical address, and will be passed to the monitor instruction in register `EAX`. The *extensions* parameter contains optional extensions to the monitor hardware which will be passed in `ECX`. The *hints* parameter will contain hints to the monitor hardware, which will be passed in `EDX`. A non-zero value for *extensions* will cause a general protection fault.

_mm_mwait

```
extern void _mm_mwait(unsigned extensions, unsigned hints);
```

Generates the `MWAIT` instruction. This instruction is a hint that allows the processor to stop execution and enter an implementation-dependent optimized state until occurrence of a class of events. In future processor designs, *extensions* and *hints* parameters may be used to convey additional information to the processor. All non-zero values of *extensions* and *hints* are reserved. A non-zero value for *extensions* will cause a general protection fault.

Intrinsics for Intel® Streaming SIMD Extensions 2 (Intel® SSE2)

This section describes the C++ language-level features supporting the Intel® Streaming SIMD Extensions 2 (Intel® SSE2) in the Intel® C++ Compiler Classic. The features are divided into two categories:

- Floating-Point Intrinsics -- describes the arithmetic, logical, compare, conversion, memory, and initialization intrinsics for the double-precision floating-point data type (`__m128d`).

- Integer Intrinsics -- describes the arithmetic, logical, compare, conversion, memory, and initialization intrinsics for the extended-precision integer data type (`__m128i`).

The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

NOTE
There are no intrinsics for floating-point move operations. To move data from one register to another, a simple assignment, `A = B`, suffices, where `A` and `B` are the source and target registers for the move operation.

Some intrinsics are "composites" - they require more than one instruction to implement them. Intrinsics that require one instruction to implement them are referred to as "simple".

You should be familiar with the hardware features provided by Intel® SSE2 when writing programs with the intrinsics. The following are three important issues to keep in mind:

- Certain intrinsics, such as `_mm_loadr_pd` and `_mm_cmpgt_sd`, are not directly supported by the instruction set. While these intrinsics are convenient programming aids, be mindful of their implementation cost.
- Data loaded or stored as `__m128d` objects must be generally 16-byte-aligned.
- Some intrinsics require that their argument be immediates, that is, constant integers (literals), due to the nature of the instruction.

Macro Functions

The macro function intrinsics listed here were designed for the Intel® Pentium® 4 processor with Streaming SIMD Extensions 3 (Intel® SSE3). They are also compatible with Streaming SIMD Extensions 2 (Intel® SSE2).

The prototypes for these intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

_MM_SET_DENORMALS_ZERO_MODE

`_MM_SET_DENORMALS_ZERO_MODE(x);`

Macro arguments: either `_MM_DENORMALS_ZERO_ON`, `_MM_DENORMALS_ZERO_OFF`.

This macro causes "denormals are zero" mode to be turned ON or OFF by setting the appropriate bit of the control register.

_MM_GET_DENORMALS_ZERO_MODE

`_MM_GET_DENORMALS_ZERO_MODE();`

No arguments.

This macro returns the current value of the denormals are zero mode bit of the control register.

Floating-point Intrinsics

Arithmetic Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for floating-point arithmetic operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in a register. The information about what is placed in each register appears in the tables below, in the detailed explanation for each intrinsic. For each intrinsic, the resulting register is represented by `R0` and `R1`, where `R0` and `R1` each represent one piece of the result register.

Intrinsic Name	**Operation**	**Corresponding Intel® SSE2 Instruction**
`_mm_add_sd`	Addition	`ADDSD`
`_mm_add_pd`	Addition	`ADDPD`
`_mm_sub_sd`	Subtraction	`SUBSD`
`_mm_sub_pd`	Subtraction	`SUBPD`
`_mm_mul_sd`	Multiplication	`MULSD`
`_mm_mul_pd`	Multiplication	`MULPD`
`_mm_div_sd`	Division	`DIVSD`
`_mm_div_pd`	Division	`DIVPD`
`_mm_sqrt_sd`	Computes Square Root	`SQRTSD`
`_mm_sqrt_pd`	Computes Square Root	`SQRTPD`
`_mm_min_sd`	Computes Minimum	`MINSD`
`_mm_min_pd`	Computes Minimum	`MINPD`
`_mm_max_sd`	Computes Maximum	`MAXSD`
`_mm_max_pd`	Computes Maximum	`MAXPD`

_mm_add_sd

```
__m128d _mm_add_sd(__m128d a, __m128d b);
```

Adds the lower double-precision FP (floating-point) values of *a* and *b*; the upper double-precision FP value is passed through from *a*.

R0	**R1**
`a0 + b0`	`a1`

_mm_add_pd

```
__m128d _mm_add_pd(__m128d a, __m128d b);
```

Adds the two DP FP values of *a* and *b*.

R0	R1
`a0 + b0`	`a1 + b1`

_mm_sub_sd

`__m128d _mm_sub_sd(__m128d a, __m128d b);`

Subtracts the lower DP FP value of *b* from *a*. The upper DP FP value is passed through from *a*.

R0	R1
`a0 - b0`	`a1`

_mm_sub_pd

`__m128d _mm_sub_pd(__m128d a, __m128d b);`

Subtracts the two DP FP values of *b* from *a*.

R0	R1
`a0 - b0`	`a1 - b1`

_mm_mul_sd

`__m128d _mm_mul_sd(__m128d a, __m128d b);`

Multiplies the lower DP FP values of *a* and *b*. The upper DP FP is passed through from *a*.

R0	R1
`a0 * b0`	`a1`

_mm_mul_pd

`__m128d _mm_mul_pd(__m128d a, __m128d b);`

Multiplies the two DP FP values of *a* and `b`.

R0	R1
`a0 * b0`	`a1 * b1`

_mm_div_sd

`__m128d _mm_div_sd(__m128d a, __m128d b);`

Divides the lower DP FP values of *a* and *b*. The upper DP FP value is passed through from *a*.

R0	R1
`a0 / b0`	`a1`

_mm_div_pd

```
__m128d _mm_div_pd(__m128d a, __m128d b);
```

Divides the two DP FP values of *a* and *b*.

R0	R1
`a0 / b0`	`a1 / b1`

_mm_sqrt_sd

```
__m128d _mm_sqrt_sd(__m128d a, __m128d b);
```

Computes the square root of the lower DP FP value of *b*. The upper DP FP value is passed through from *a*.

R0	R1
`sqrt(b0)`	`a1`

_mm_sqrt_pd

```
__m128d _mm_sqrt_pd(__m128d a);
```

Computes the square root of the two DP FP values of *a*.

R0	R1
`sqrt(a0)`	`sqrt(a1)`

_mm_min_sd

```
__m128d _mm_min_sd(__m128d a, __m128d b);
```

Computes the minimum of the lower DP FP values of *a* and *b*. The upper DP FP value is passed through from *a*.

R0	R1
`min (a0, b0)`	`a1`

_mm_min_pd

```
__m128d _mm_min_pd(__m128d a, __m128d b);
```

Computes the minima of the two DP FP values of *a* and *b*.

R0	R1
`min (a0, b0)`	`min(a1, b1)`

_mm_max_sd

```
__m128d _mm_max_sd(__m128d a, __m128d b);
```

Computes the maximum of the lower DP FP values of *a* and *b*. The upper DP FP value is passed through from *a*.

R0	R1
`max (a0, b0)`	`a1`

_mm_max_pd

```
__m128d _mm_max_pd(__m128d a, __m128d b);
```

Computes the maxima of the two DP FP values of *a* and *b*.

R0	R1
`max (a0, b0)`	`max (a1, b1)`

Logical Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for floating-point logical operations are listed in the following table. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation for each intrinsic. For each intrinsic, the resulting register is represented by `R0` and `R1`, where `R0` and `R1` each represent one piece of the result register.

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_and_pd`	Computes AND	`ANDPD`
`_mm_andnot_pd`	Computes AND and NOT	`ANDNPD`
`_mm_or_pd`	Computes OR	`ORPD`
`_mm_xor_pd`	Computes XOR	`XORPD`

_mm_and_pd

```
__m128d _mm_and_pd(__m128d a, __m128d b);
```

Computes the bitwise `AND` of the two DP FP values of *a* and *b*.

R0	R1
`a0 & b0`	`a1 & b1`

_mm_andnot_pd

```
__m128d _mm_andnot_pd(__m128d a, __m128d b);
```

Computes the bitwise `AND` of the 128-bit value in *b* and the bitwise `NOT` of the 128-bit value in *a*.

R0	R1
`(~a0) & b0`	`(~a1) & b1`

_mm_or_pd

`__m128d _mm_or_pd(__m128d a, __m128d b);`

Computes the bitwise `OR` of the two DP FP values of `a` and *b*.

R0	R1
`a0 | b0`	`a1 | b1`

_mm_xor_pd

`__m128d _mm_xor_pd(__m128d a, __m128d b);`

Computes the bitwise `XOR` of the two DP FP values of *a* and *b*.

R0	R1
`a0 ^ b0`	`a1 ^ b1`

Compare Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for floating-point comparision operations are listed in the following table. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Each comparison intrinsic performs a comparison of *a* and *b*. For the packed form, the two double-precision FP values of *a* and *b* are compared, and a 128-bit mask is returned. For the scalar form, the lower double-precision FP values of *a* and *b* are compared, and a 64-bit mask is returned; the upper double-precision FP value is passed through from *a*.

The mask is set to `0xffffffffffffffff` for each element where the comparison is true, and set to `0x0` where the comparison is false. The `r` following the instruction name indicates that the operands to the instruction are reversed in the actual implementation.

The results of each intrinsic operation are placed in a register. The information about what is placed in each register appears in the tables below, in the detailed explanation for each intrinsic. For each intrinsic, the resulting register is represented by `R`, `R0`, and `R1`, where `R`, `R0`, and `R1` each represent one piece of the result register.

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_cmpeq_pd`	Equality	`CMPEQPD`
`_mm_cmplt_pd`	Less Than	`CMPLTPD`
`_mm_cmple_pd`	Less Than or Equal	`CMPLEPD`
`_mm_cmpgt_pd`	Greater Than	`CMPLTPDr`

Intrinsic Name	**Operation**	**Corresponding Intel® SSE2 Instruction**
`_mm_cmpge_pd`	Greater Than or Equal	`CMPLEPDr`
`_mm_cmpord_pd`	Ordered	`CMPORDPD`
`_mm_cmpunord_pd`	Unordered	`CMPUNORDPD`
`_mm_cmpneq_pd`	Inequality	`CMPNEQPD`
`_mm_cmpnlt_pd`	Not Less Than	`CMPNLTPD`
`_mm_cmpnle_pd`	Not Less Than or Equal	`CMPNLEPD`
`_mm_cmpngt_pd`	Not Greater Than	`CMPNLTPDr`
`_mm_cmpnge_pd`	Not Greater Than or Equal	`CMPNLEPDr`
`_mm_cmpeq_sd`	Equality	`CMPEQSD`
`_mm_cmplt_sd`	Less Than	`CMPLTSD`
`_mm_cmple_sd`	Less Than or Equal	`CMPLESD`
`_mm_cmpgt_sd`	Greater Than	`CMPLTSDr`
`_mm_cmpge_sd`	Greater Than or Equal	`CMPLESDr`
`_mm_cmpord_sd`	Ordered	`CMPORDSD`
`_mm_cmpunord_sd`	Unordered	`CMPUNORDSD`
`_mm_cmpneq_sd`	Inequality	`CMPNEQSD`
`_mm_cmpnlt_sd`	Not Less Than	`CMPNLTSD`
`_mm_cmpnle_sd`	Not Less Than or Equal	`CMPNLESD`
`_mm_cmpngt_sd`	Not Greater Than	`CMPNLTSDr`
`_mm_cmpnge_sd`	Not Greater Than or Equal	`CMPNLESDr`
`_mm_comieq_sd`	Equality	`COMISD`
`_mm_comilt_sd`	Less Than	`COMISD`
`_mm_comile_sd`	Less Than or Equal	`COMISD`
`_mm_comigt_sd`	Greater Than	`COMISD`
`_mm_comige_sd`	Greater Than or Equal	`COMISD`
`_mm_comineq_sd`	Not Equal	`COMISD`
`_mm_ucomieq_sd`	Equality	`UCOMISD`
`_mm_ucomilt_sd`	Less Than	`UCOMISD`
`_mm_ucomile_sd`	Less Than or Equal	`UCOMISD`

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_ucomigt_sd`	Greater Than	`UCOMISD`
`_mm_ucomige_sd`	Greater Than or Equal	`UCOMISD`
`_mm_ucomineq_sd`	Not Equal	`UCOMISD`

_mm_cmpeq_pd

```
__m128d _mm_cmpeq_pd(__m128d a, __m128d b);
```

Compares the two DP FP values of *a* and *b* for equality.

R0	R1
`(a0 == b0) ? 0xffffffffffffffff : 0x0`	`(a1 == b1) ? 0xffffffffffffffff : 0x0`

_mm_cmplt_pd

```
__m128d _mm_cmplt_pd(__m128d a, __m128d b);
```

Compares the two DP FP values of *a* and *b* for *a* less than *b*.

R0	R1
`(a0 < b0) ? 0xffffffffffffffff : 0x0`	`(a1 < b1) ? 0xffffffffffffffff : 0x0`

_mm_cmple_pd

```
__m128d _mm_cmple_pd(__m128d a, __m128d b);
```

Compares the two DP FP values of *a* and *b* for *a* less than or equal to *b*.

R0	R1
`(a0 <= b0) ? 0xffffffffffffffff : 0x0`	`(a1 <= b1) ? 0xffffffffffffffff : 0x0`

_mm_cmpgt_pd

```
__m128d _mm_cmpgt_pd(__m128d a, __m128d b);
```

Compares the two DP FP values of *a* and *b* for *a* greater than *b*.

R0	R1
`(a0 > b0) ? 0xffffffffffffffff : 0x0`	`(a1 > b1) ? 0xffffffffffffffff : 0x0`

_mm_cmpge_pd

```
__m128d _mm_cmpge_pd(__m128d a, __m128d b);
```

Compares the two DP FP values of *a* and *b* for *a* greater than or equal to *b*.

R0	R1
`(a0 >= b0) ? 0xffffffffffffffff : 0x0`	`(a1 >= b1) ? 0xffffffffffffffff : 0x0`

_mm_cmpord_pd

```
__m128d _mm_cmpord_pd(__m128d a, __m128d b);
```

Compares the two DP FP values of *a* and *b* for ordered.

R0	R1
`(a0 ord b0) ? 0xffffffffffffffff : 0x0`	`(a1 ord b1) ? 0xffffffffffffffff : 0x0`

_mm_cmpunord_pd

```
__m128d _mm_cmpunord_pd(__m128d a, __m128d b);
```

Compares the two DP FP values of *a* and *b* for unordered.

R0	R1
`(a0 unord b0) ? 0xffffffffffffffff : 0x0`	`(a1 unord b1) ? 0xffffffffffffffff : 0x0`

_mm_cmpneq_pd

```
__m128d _mm_cmpneq_pd( __m128d a, __m128d b);
```

Compares the two DP FP values of *a* and *b* for inequality.

R0	R1
`(a0 != b0) ? 0xffffffffffffffff : 0x0`	`(a1 != b1) ? 0xffffffffffffffff : 0x0`

_mm_cmpnlt_pd

```
__m128d _mm_cmpnlt_pd(__m128d a, __m128d b);
```

Compares the two DP FP values of *a* and *b* for *a* not less than *b*.

R0	R1
`!(a0 < b0) ? 0xffffffffffffffff : 0x0`	`!(a1 < b1) ? 0xffffffffffffffff : 0x0`

_mm_cmpnle_pd

```
__m128d _mm_cmpnle_pd(__m128d a, __m128d b);
```

Compares the two DP FP values of *a* and *b* for *a* not less than or equal to *b*.

R0	R1
`!(a0 <= b0) ? 0xffffffffffffffff : 0x0`	`!(a1 <= b1) ? 0xffffffffffffffff : 0x0`

_mm_cmpngt_pd

```
__m128d _mm_cmpngt_pd(__m128d a, __m128d b);
```

Compares the two DP FP values of *a* and `b` for *a* not greater than *b*.

b **R0**	**R1**
`!(a0 > b0) ? 0xffffffffffffffff : 0x0`	`!(a1 > b1) ? 0xffffffffffffffff : 0x0`

_mm_cmpnge_pd

```
__m128d _mm_cmpnge_pd(__m128d a, __m128d b);
```

Compares the two DP FP values of *a* and *b* for *a* not greater than or equal to *b*.

R0	**R1**
`!(a0 >= b0) ? 0xffffffffffffffff : 0x0`	`!(a1 >= b1) ? 0xffffffffffffffff : 0x0`

_mm_cmpeq_sd

```
__m128d _mm_cmpeq_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for equality. The upper DP FP value is passed through from *a*.

R0	**R1**
`(a0 == b0) ? 0xffffffffffffffff : 0x0`	`a1`

_mm_cmplt_sd

```
__m128d _mm_cmplt_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* less than *b*. The upper DP FP value is passed through from *a*.

R0	**R1**
`(a0 < b0) ? 0xffffffffffffffff : 0x0`	`a1`

_mm_cmple_sd

```
__m128d _mm_cmple_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* less than or equal to *b*. The upper DP FP value is passed through from *a*.

R0	**R1**
`(a0 <= b0) ? 0xffffffffffffffff : 0x0`	`a1`

_mm_cmpgt_sd

```
__m128d _mm_cmpgt_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* greater than *b*. The upper DP FP value is passed through from *a*.

R0	R1
`(a0 > b0) ? 0xffffffffffffffff : 0x0`	a1

_mm_cmpge_sd

```
__m128d _mm_cmpge_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* greater than or equal to *b*. The upper DP FP value is passed through from *a*.

R0	R1
`(a0 >= b0) ? 0xffffffffffffffff : 0x0`	`a1`

_mm_cmpord_sd

```
__m128d _mm_cmpord_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for ordered. The upper DP FP value is passed through from *a*.

R0	R1
`(a0 ord b0) ? 0xffffffffffffffff : 0x0`	`a1`

_mm_cmpunord_sd

```
__m128d _mm_cmpunord_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for unordered. The upper DP FP value is passed through from *a*.

R0	R1
`(a0 unord b0) ? 0xffffffffffffffff : 0x0`	`a1`

_mm_cmpneq_sd

```
__m128d _mm_cmpneq_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for inequality. The upper DP FP value is passed through from *a*.

R0	R1
`(a0 != b0) ? 0xffffffffffffffff : 0x0`	`a1`

_mm_cmpnlt_sd

```
__m128d _mm_cmpnlt_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* not less than *b*. The upper DP FP value is passed through from *a*.

R0	R1
`!(a0 < b0) ? 0xffffffffffffffff : 0x0`	`a1`

_mm_cmpnle_sd

```
__m128d _mm_cmpnle_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* not less than or equal to *b*. The upper DP FP value is passed through from *a*.

R0	R1
!(a0 <= b0) ? 0xffffffffffffffff : 0x0	a1

_mm_cmpngt_sd

```
__m128d _mm_cmpngt_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* not greater than *b*. The upper DP FP value is passed through from *a*.

R0	R1
`!(a0 > b0) ? 0xffffffffffffffff : 0x0`	`a1`

_mm_cmpnge_sd

```
__m128d _mm_cmpnge_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* not greater than or equal to *b*. The upper DP FP value is passed through from *a*.

R0	R1
`!(a0 >= b0) ? 0xffffffffffffffff : 0x0`	`a1`

_mm_comieq_sd

```
int _mm_comieq_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* equal to *b*. If *a* and *b* are equal, 1 is returned. Otherwise, 0 is returned.

R
`(a0 == b0) ? 0x1 : 0x0`

_mm_comilt_sd

```
int _mm_comilt_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* less than *b*. If *a* is less than *b*, 1 is returned. Otherwise, 0 is returned.

R
`(a0 < b0) ? 0x1 : 0x0`

_mm_comile_sd

```
int _mm_comile_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for a less than or equal to *b*. If *a* is less than or equal to *b*, 1 is returned. Otherwise, 0 is returned.

R
`(a0 <= b0) ? 0x1 : 0x0`

_mm_comigt_sd

```
int _mm_comigt_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* greater than *b*. If *a* is greater than *b* are equal, 1 is returned. Otherwise, 0 is returned.

R
`(a0 > b0) ? 0x1 : 0x0`

_mm_comige_sd

```
int _mm_comige_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* greater than or equal to *b*. If *a* is greater than or equal to *b*, 1 is returned. Otherwise, 0 is returned.

R
`(a0 >= b0) ? 0x1 : 0x0`

_mm_comineq_sd

```
int _mm_comineq_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of `a` and *b* for *a* not equal to *b*. If *a* and *b* are not equal, 1 is returned. Otherwise, 0 is returned.

R
`(a0 != b0) ? 0x1 : 0x0`

_mm_ucomieq_sd

```
int _mm_ucomieq_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for `a` equal to *b*. If *a* and *b* are equal, 1 is returned. Otherwise, 0 is returned.

R
(a0 == b0) ? 0x1 : 0x0

_mm_ucomilt_sd

```
int _mm_ucomilt_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* less than *b*. If a is less than *b*, 1 is returned. Otherwise, 0 is returned.

R
(a0 < b0) ? 0x1 : 0x0

_mm_ucomile_sd

```
int _mm_ucomile_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for a less than or equal to *b*. If *a* is less than or equal to *b*, 1 is returned. Otherwise, 0 is returned.

R
(a0 <= b0) ? 0x1 : 0x0

_mm_ucomigt_sd

```
int _mm_ucomigt_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for a greater than *b*. If *a* is greater than *b* are equal, 1 is returned. Otherwise, 0 is returned.

R
(a0 > b0) ? 0x1 : 0x0

_mm_ucomige_sd

```
int _mm_ucomige_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* greater than or equal to *b*. If *a* is greater than or equal to *b*, 1 is returned. Otherwise, 0 is returned.

R
(a0 >= b0) ? 0x1 : 0x0

_mm_ucomineq_sd

```
int _mm_ucomineq_sd(__m128d a, __m128d b);
```

Compares the lower DP FP value of *a* and *b* for *a* not equal to *b*. If *a* and *b* are not equal, 1 is returned. Otherwise, 0 is returned.

R
(a0 != b0) ? 0x1 : 0x0

Conversion Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for floating-point conversion operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Each conversion intrinsic takes one data type and performs a conversion to a different type. Some conversions, such as those performed by the `_mm_cvtpd_ps` intrinsic, result in a loss of precision. The rounding mode used in such cases is determined by the value in the `MXCSR` register. The default rounding mode is round-to-nearest.

> **NOTE**
> The rounding mode used by the C and C++ languages when performing a type conversion is to truncate. The `_mm_cvttpd_epi32` and `_mm_cvttsd_si32` intrinsics use the truncate rounding mode regardless of the mode specified by the `MXCSR` register.

The results of each intrinsic operation are placed in a register. The information about what is placed in each register appears in the tables below, in the detailed explanation for each intrinsic. For each intrinsic, the resulting register is represented by `R`, `R0`, `R1`, `R2`, and `R3`, where each represent the registers in which results are placed.

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_cvtpd_ps`	Convert DP FP to SP FP	`CVTPD2PS`
`_mm_cvtps_pd`	Convert from SP FP to DP FP	`CVTPS2PD`
`_mm_cvtepi32_pd`	Convert lower integer values to DP FP	`CVTDQ2PD`
`_mm_cvtpd_epi32`	Convert DP FP values to integer values	`CVTPD2DQ`
`_mm_cvtsd_si32`	Convert lower DP FP value to integer value	`CVTSD2SI`
`_mm_cvtsd_ss`	Convert lower DP FP value to SP FP	`CVTSD2SS`
`_mm_cvtsi32_sd`	Convert signed integer value to DP FP	`CVTSI2SD`
`_mm_cvtss_sd`	Convert lower SP FP value to DP FP	`CVTSS2SD`
`_mm_cvttpd_epi32`	Convert DP FP values to signed integers	`CVTTPD2DQ`

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_cvttsd_si32`	Convert lower DP FP to signed integer	`CVTTSD2SI`
`_mm_cvtpd_pi32`	Convert two DP FP values to signed integer values	`CVTPD2PI`
`_mm_cvttpd_pi32`	Convert two DP FP values to signed integer values using truncate	`CVTTPD2PI`
`_mm_cvtpi32_pd`	Convert two signed integer values to DP FP	`CVTPI2PD`
`_mm_cvtsd_f64`	Extract DP FP value from first vector element	None

_mm_cvtpd_ps

```
__m128 _mm_cvtpd_ps(__m128d a);
```

Converts the two DP FP values of *a* to SP FP values.

R0	R1	R2	R3
`(float) a0`	`(float) a1`	`0.0`	`0.0`

_mm_cvtps_pd

```
__m128d _mm_cvtps_pd(__m128 a);
```

Converts the lower two SP FP values of *a* to DP FP values.

R0	R1
`(double) a0`	`(double) a1`

_mm_cvtepi32_pd

```
__m128d _mm_cvtepi32_pd(__m128i a);
```

Converts the lower two signed 32-bit integer values of *a* to DP FP values.

R0	R1
`(double) a0`	`(double) a1`

_mm_cvtpd_epi32

```
__m128i _mm_cvtpd_epi32(__m128d a);
```

Converts the two DP FP values of *a* to 32-bit signed integer values.

R0	R1	R2	R3
`(int) a0`	`(int) a1`	`0x0`	`0x0`

_mm_cvtsd_si32

```
int _mm_cvtsd_si32(__m128d a);
```

Converts the lower DP FP value of *a* to a 32-bit signed integer value.

R
`(int) a0`

_mm_cvtsd_ss

```
__m128 _mm_cvtsd_ss(__m128 a, __m128d b);
```

Converts the lower DP FP value of *b* to an SP FP value. The upper SP FP values in *a* are passed through.

R0	R1	R2	R3
`(float) b0`	`a1`	`a2`	`a3`

_mm_cvtsi32_sd

```
__m128d _mm_cvtsi32_sd(__m128d a, int b);
```

Converts the signed integer value in *b* to a DP FP value. The upper DP FP value in *a* is passed through.

R0	R1
`(double) b`	`a1`

_mm_cvtss_sd

```
__m128d _mm_cvtss_sd(__m128d a, __m128 b);
```

Converts the lower SP FP value of *b* to a DP FP value. The upper value DP FP value in *a* is passed through.

R0	R1
`(double) b0`	`a1`

_mm_cvttpd_epi32

```
__m128i _mm_cvttpd_epi32(__m128d a);
```

Converts the two DP FP values of *a* to 32-bit signed integers using truncate.

R0	R1	R2	R3
`(int) a0`	`(int) a1`	`0x0`	`0x0`

_mm_cvttsd_si32

```
int _mm_cvttsd_si32(__m128d a);
```

Converts the lower DP FP value of *a* to a 32-bit signed integer using truncate.

R
(int) a0

_mm_cvtpd_pi32

```
__m64 _mm_cvtpd_pi32(__m128d a);
```

Converts the two DP FP values of *a* to 32-bit signed integer values.

R0	R1
(int)a0	(int) a1

_mm_cvttpd_pi32

```
__m64 _mm_cvttpd_pi32(__m128d a);
```

Converts the two DP FP values of *a* to 32-bit signed integer values using truncate.

R0	R1
(int)a0	(int) a1

_mm_cvtpi32_pd

```
__m128d _mm_cvtpi32_pd(__m64 a);
```

Converts the two 32-bit signed integer values of *a* to DP FP values.

R0	R1
(double)a0	(double)a1

_mm_cvtsd_f64

```
double _mm_cvtsd_f64(__m128d a);
```

This intrinsic extracts a double precision floating point value from the first vector element of an `__m128d`. It does so in the most efficient manner possible in the context used.

> **NOTE**
> This intrinsic does not map to any specific Intel® SSE2 instruction.

Load Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for floating-point load operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The load and set operations are similar in that both initialize `__m128d` data. However, the set operations take a double argument and are intended for initialization with constants, while the load operations take a double pointer argument and are intended to mimic the instructions for loading data from memory.

The results of each intrinsic operation are placed in a register. The information about what is placed in each register appears in the tables below, in the detailed explanation for each intrinsic. For each intrinsic, the resulting register is represented by R0 and R1, where R0 and R1 each represent one piece of the result register.

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
_mm_load_pd	Loads two DP FP values	MOVAPD
_mm_load1_pd	Loads a single DP FP value, copying to both elements	MOVSD + shuffling
_mm_loadr_pd	Loads two DP FP values in reverse order	MOVAPD + shuffling
_mm_loadu_pd	Loads two DP FP values	MOVUPD
_mm_load_sd	Loads a DP FP value, sets upper DP FP to zero	MOVSD
_mm_loadh_pd	Loads a DP FP value as the upper DP FP value of the result	MOVHPD
_mm_loadl_pd	Loads a DP FP value as the lower DP FP value of the result	MOVLPD

_mm_load_pd

`__m128d _mm_load_pd(double const*dp);`

Loads two DP FP values. The address *p* must be 16-byte aligned.

R0	R1
p[0]	p[1]

_mm_load1_pd

`__m128d _mm_load1_pd(double const*dp);`

Loads a single DP FP value, copying to both elements. The address *p* need not be 16-byte aligned.

R0	R1
*p	*p

_mm_loadr_pd

`__m128d _mm_loadr_pd(double const*dp);`

Loads two DP FP values in reverse order. The address *p* must be 16-byte aligned.

R0	R1
p[1]	p[0]

_mm_loadu_pd

```
__m128d _mm_loadu_pd(double const*dp);
```

Loads two DP FP values. The address *p* need not be 16-byte aligned.

R0	R1
p[0]	p[1]

_mm_load_sd

```
__m128d _mm_load_sd(double const*dp);
```

Loads a DP FP value. The upper DP FP is set to zero. The address *p* need not be 16-byte aligned.

R0	R1
*p	0.0

_mm_loadh_pd

```
__m128d _mm_loadh_pd(__m128d a, double const*dp);
```

Loads a DP FP value as the upper DP FP value of the result. The lower DP FP value is passed through from *a*. The address *p* need not be 16-byte aligned.

R0	R1
a0	*p

_mm_loadl_pd

```
__m128d _mm_loadl_pd(__m128d a, double const*dp);
```

Loads a DP FP value as the lower DP FP value of the result. The upper DP FP value is passed through from *a*. The address *p* need not be 16-byte aligned.

R0	R1
*p	a1

Set Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for floating-point set operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The load and set operations are similar in that both initialize `__m128d` data. However, the set operations take a double argument and are intended for initialization with constants, while the load operations take a double pointer argument and are intended to mimic the instructions for loading data from memory.

Some of the these intrinsics are composite intrinsics because they require more than one instruction to implement them.

The results of each intrinsic operation are placed in a register. The information about what is placed in each register appears in the tables below, in the detailed explanation for each intrinsic. For each intrinsic, the resulting register is represented by `R0` and `R1`, where `R0` and `R1` each represent one piece of the result register.

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_set_sd`	Sets lower DP FP value to *w* and upper to zero	`Composite`
`_mm_set1_pd`	Sets two DP FP values to *w*	`Composite`
`_mm_set_pd`	Sets lower DP FP to *x* and upper to *w*	`Composite`
`_mm_setr_pd`	Sets lower DP FP to *w* and upper to *x*	`Composite`
`_mm_setzero_pd`	Sets two DP FP values to zero	`XORPD`
`_mm_move_sd`	Sets lower DP FP value to the lower DP FP value of *b*	`MOVSD`

_mm_set_sd

```
__m128d _mm_set_sd(double w);
```

Sets the lower DP FP value to *w* and sets the upper DP FP value to zero.

R0	R1
`w`	`0.0`

_mm_set1_pd

```
__m128d _mm_set1_pd(double w);
```

Sets the two DP FP values to *w*.

R0	R1
`w`	`w`

_mm_set_pd

```
__m128d _mm_set_pd(double w, double x);
```

Sets the lower DP FP value to *x* and sets the upper DP FP value to *w*.

R0	R1
x	w

_mm_setr_pd

```
__m128d _mm_setr_pd(double w, double x);
```

Sets the lower DP FP value to *w* and sets the upper DP FP value to *x*. `r0 := w r1 := x`

R0	R1
w	x

_mm_setzero_pd

```
__m128d _mm_setzero_pd(void);
```

Sets the two DP FP values to zero.

R0	R1
0.0	0.0

_mm_move_sd

```
__m128d _mm_move_sd( __m128d a, __m128d b);
```

Sets the lower DP FP value to the lower DP FP value of *b*. The upper DP FP value is passed through from *a*.

R0	R1
b0	a1

Store Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for floating-point store operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The store operations assign the initialized data to the address.

The detailed description of each intrinsic contains a table detailing the returns. In these tables, *dp[n]* is an access to the *n* element of the result.

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_stream_pd`	Store	`MOVNTPD`
`_mm_store_sd`	Store	`MOVSD`
`_mm_store1_pd`	Store	`MOVAPD` + shuffling
`_mm_store_pd`	Store	`MOVAPD`

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_storeu_pd`	Store	`MOVUPD`
`_mm_storer_pd`	Store	`MOVAPD` + shuffling
`_mm_storeh_pd`	Store	`MOVHPD`
`_mm_storel_pd`	Store	`MOVLPD`

_mm_store_sd

```
void _mm_store_sd(double *dp, __m128d a);
```

Stores the lower DP FP value of *a*. The address *dp* needs not be 16-byte aligned.

*dp
a0

_mm_store1_pd

```
void _mm_store1_pd(double *dp, __m128d a);
```

Stores the lower DP FP value of *a* twice. The address *dp* must be 16-byte aligned.

dp[0]	dp[1]
a0	a0

_mm_store_pd

```
void _mm_store_pd(double *dp, __m128d a);
```

Stores two DP FP values. The address *dp* must be 16-byte aligned.

dp[0]	dp[1]
a0	a1

_mm_storeu_pd

```
void _mm_storeu_pd(double *dp, __m128d a);
```

Stores two DP FP values. The address *dp* need not be 16-byte aligned.

dp[0]	dp[1]
a0	a1

_mm_storer_pd

```
void _mm_storer_pd(double *dp, __m128d a);
```

Stores two DP FP values in reverse order. The address *dp* must be 16-byte aligned.

dp[0]	dp[1]
a1	a0

_mm_storeh_pd

```
void _mm_storeh_pd(double *dp, __m128d a);
```

Stores the upper DP FP value of *a*.

*dp
a1

```
void _mm_storel_pd(double *dp, __m128d a);
```

Stores the lower DP FP value of `a`.

*dp
a0

Integer Intrinsics

Arithmetic Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer arithmetic operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. `R`, `R0`, `R1`, ..., `R15` represent the registers in which results are placed.

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
_mm_add_epi8	Addition	PADDB
_mm_add_epi16	Addition	PADDW
_mm_add_epi32	Addition	PADDD
_mm_add_si64	Addition	PADDQ
_mm_add_epi64	Addition	PADDQ
_mm_adds_epi8	Addition	PADDSB
_mm_adds_epi16	Addition	PADDSW
_mm_adds_epu8	Addition	PADDUSB
_mm_adds_epu16	Addition	PADDUSW

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
_mm_avg_epu8	Computes Average	PAVGB
_mm_avg_epu16	Computes Average	PAVGW
_mm_madd_epi16	Multiplication and Addition	PMADDWD
_mm_max_epi16	Computes Maxima	PMAXSW
_mm_max_epu8	Computes Maxima	PMAXUB
_mm_min_epi16	Computes Minima	PMINSW
_mm_min_epu8	Computes Minima	PMINUB
_mm_mulhi_epi16	Multiplication	PMULHW
_mm_mulhi_epu16	Multiplication	PMULHUW
_mm_mullo_epi16	Multiplication	PMULLW
_mm_mul_su32	Multiplication	PMULUDQ
_mm_mul_epu32	Multiplication	PMULUDQ
_mm_sad_epu8	Computes Difference/Adds	PSADBW
_mm_sub_epi8	Subtraction	PSUBB
_mm_sub_epi16	Subtraction	PSUBW
_mm_sub_epi32	Subtraction	PSUBD
_mm_sub_si64	Subtraction	PSUBQ
_mm_sub_epi64	Subtraction	PSUBQ
_mm_subs_epi8	Subtraction	PSUBSB
_mm_subs_epi16	Subtraction	PSUBSW
_mm_subs_epu8	Subtraction	PSUBUSB
_mm_subs_epu16	Subtraction	PSUBUSW

_mm_add_epi8

```
__m128i _mm_add_epi8(__m128i a, __m128i b);
```

Adds the 16 signed or unsigned 8-bit integers in *a* to the 16 signed or unsigned 8-bit integers in *b*.

R0	R1	...	R15
a0 + b0	a1 + b1;	...	a15 + b15

_mm_add_epi16

```
__m128i _mm_add_epi16(__m128i a, __m128i b);
```

Adds the eight signed or unsigned 16-bit integers in *a* to the eight signed or unsigned 16-bit integers in *b*.

R0	R1	...	R7
a0 + b0	a1 + b1	...	a7 + b7

_mm_add_epi32

```
__m128i _mm_add_epi32(__m128i a, __m128i b);
```

Adds the four signed or unsigned 32-bit integers in *a* to the four signed or unsigned 32-bit integers in *b*.

R0	R1	R2	R3
a0 + b0	a1 + b1	a2 + b2	a3 + b3

_mm_add_si64

```
__m64 _mm_add_si64(__m64 a, __m64 b);
```

Adds the signed or unsigned 64-bit integer *a* to the signed or unsigned 64-bit integer *b*.

R0
a + b

_mm_add_epi64

```
__m128i _mm_add_epi64(__m128i a, __m128i b);
```

Adds the two signed or unsigned 64-bit integers in *a* to the two signed or unsigned 64-bit integers in *b*.

R0	R1
a0 + b0	a1 + b1

_mm_adds_epi8

```
__m128i _mm_adds_epi8(__m128i a, __m128i b);
```

Adds the 16 signed 8-bit integers in *a* to the 16 signed 8-bit integers in *b* using saturating arithmetic.

R0	R1	...	R15
SignedSaturate (a0 + b0)	SignedSaturate (a1 + b1)	...	SignedSaturate (a15 + b15)

_mm_adds_epi16

```
__m128i _mm_adds_epi16(__m128i a, __m128i b);
```

Adds the eight signed 16-bit integers in *a* to the eight signed 16-bit integers in *b* using saturating arithmetic.

R0	R1	...	R7
SignedSaturate (a0 + b0)	SignedSaturate (a1 + b1)	...	SignedSaturate (a7 + b7)

_mm_adds_epu8

```
__m128i _mm_adds_epu8(__m128i a, __m128i b);
```

Adds the 16 unsigned 8-bit integers in *a* to the 16 unsigned 8-bit integers in *b* using saturating arithmetic.

R0	R1	...	R15
UnsignedSaturate (a0 + b0)	UnsignedSaturate (a1 + b1)	...	UnsignedSaturate (a15 + b15)

_mm_adds_epu16

```
__m128i _mm_adds_epu16(__m128i a, __m128i b);
```

Adds the eight unsigned 16-bit integers in *a* to the eight unsigned 16-bit integers in *b* using saturating arithmetic.

R0	R1	...	R7
UnsignedSaturate (a0 + b0)	UnsignedSaturate (a1 + b1)	...	UnsignedSaturate (a7 + b7)

_mm_avg_epu8

```
__m128i _mm_avg_epu8(__m128i a, __m128i b);
```

Computes the average of the 16 unsigned 8-bit integers in *a* and the 16 unsigned 8-bit integers in *b* and rounds.

R0	R1	...	R15
(a0 + b0) / 2	(a1 + b1) / 2	...	(a15 + b15) / 2

_mm_avg_epi16

```
__m128i _mm_avg_epu16(__m128i a, __m128i b);
```

Computes the average of the eight unsigned 16-bit integers in *a* and the eight unsigned 16-bit integers in *b* and rounds.

R0	R1	...	R7
(a0 + b0) / 2	(a1 + b1) / 2	...	(a7 + b7) / 2

_mm_madd_epi16

```
__m128i _mm_madd_epi16(__m128i a, __m128i b);
```

Multiplies the eight signed 16-bit integers from *a* by the eight signed 16-bit integers from *b*. Adds the signed 32-bit integer results pairwise and packs the four signed 32-bit integer results.

R0	R1	R2	R3
`(a0 * b0) + (a1 * b1)`	`(a2 * b2) + (a3 * b3)`	`(a4 * b4) + (a5 * b5)`	`(a6 * b6) + (a7 * b7)`

_mm_max_epi16

```
__m128i _mm_max_epi16(__m128i a, __m128i b);
```

Computes the pairwise maxima of the eight signed 16-bit integers from *a* and the eight signed 16-bit integers from *b*.

R0	R1	...	R7
`max(a0, b0)`	`max(a1, b1)`	...	`max(a7, b7)`

_mm_max_epu8

```
__m128i _mm_max_epu8(__m128i a, __m128i b);
```

Computes the pairwise maxima of the 16 unsigned 8-bit integers from *a* and the 16 unsigned 8-bit integers from *b*.

R0	R1	...	R15
`max(a0, b0)`	`max(a1, b1)`	...	`max(a15, b15)`

_mm_min_epi16

```
__m128i _mm_min_epi16(__m128i a, __m128i b);
```

Computes the pairwise minima of the eight signed 16-bit integers from *a* and the eight signed 16-bit integers from *b*.

R0	R1	...	R7
`min(a0, b0)`	`min(a1, b1)`	...	`min(a7, b7)`

_mm_min_epu8

```
__m128i _mm_min_epu8(__m128i a, __m128i b);
```

Computes the pairwise minima of the 16 unsigned 8-bit integers from *a* and the 16 unsigned 8-bit integers from *b*.

R0	R1	...	R15
`min(a0, b0)`	`min(a1, b1)`	...	`min(a15, b15)`

_mm_mulhi_epi16

```
__m128i _mm_mulhi_epi16(__m128i a, __m128i b);
```

Multiplies the eight signed 16-bit integers from *a* by the eight signed 16-bit integers from *b*. Packs the upper 16-bits of the eight signed 32-bit results.

R0	R1	...	R7
(a0 * b0)[31:16]	(a1 * b1)[31:16]	...	(a7 * b7)[31:16]

_mm_mulhi_epu16

```
__m128i _mm_mulhi_epu16(__m128i a, __m128i b);
```

Multiplies the eight unsigned 16-bit integers from *a* by the eight unsigned 16-bit integers from *b*. Packs the upper 16-bits of the eight unsigned 32-bit results.

R0	R1	...	R7
(a0 * b0)[31:16]	(a1 * b1)[31:16]	...	(a7 * b7)[31:16]

_mm_mullo_epi16

```
__m128i _mm_mullo_epi16(__m128i a, __m128i b);
```

Multiplies the eight signed or unsigned 16-bit integers from *a* by the eight signed or unsigned 16-bit integers from *b*. Packs the lower 16-bits of the eight signed or unsigned 32-bit results.

R0	R1	...	R7
(a0 * b0)[15:0]	(a1 * b1)[15:0]	...	(a7 * b7)[15:0]

_mm_mul_su32

```
__m64 _mm_mul_su32(__m64 a, __m64 b);
```

Multiplies the lower 32-bit integer from *a* by the lower 32-bit integer from *b*, and returns the 64-bit integer result.

R0
a0 * b0

_mm_mul_epu32

```
__m128i _mm_mul_epu32(__m128i a, __m128i b);
```

Multiplies two unsigned 32-bit integers from *a* by two unsigned 32-bit integers from *b*. Packs the two unsigned 64-bit integer results.

R0	R1
a0 * b0	a2 * b2

_mm_sad_epu8

```
__m128i _mm_sad_epu8(__m128i a, __m128i b);
```

Computes the absolute difference of the 16 unsigned 8-bit integers from *a* and the 16 unsigned 8-bit integers from *b*. Sums the upper eight differences and lower eight differences, and packs the resulting two unsigned 16-bit integers into the upper and lower 64-bit elements.

R0	R1 to R3	R4	R5 to R7
abs(a0 - b0) + abs(a1 - b1) +...+ abs(a7 - b7)	0x0	abs(a8 - b8) + abs(a9 - b9) +...+ abs(a15 - b15)	0x0

_mm_sub_epi8

```
__m128i _mm_sub_epi8(__m128i a, __m128i b);
```

Subtracts the 16 signed or unsigned 8-bit integers of *b* from the 16 signed or unsigned 8-bit integers of *a*.

R0	R1	...	R15
a0 - b0	a1 - b1	...	a15 - b15

_mm_sub_epi16

```
__m128i _mm_sub_epi16(__m128i a, __m128i b);
```

Subtracts the eight signed or unsigned 16-bit integers of *b* from the eight signed or unsigned 16-bit integers of *a*.

R0	R1	...	R7
a0 - b0	a1 - b1	...	a7 - b7

_mm_sub_epi32

```
__m128i _mm_sub_epi32(__m128i a, __m128i b);
```

Subtracts the four signed or unsigned 32-bit integers of *b* from the four signed or unsigned 32-bit integers of *a*.

R0	R1	R2	R3
a0 - b0	a1 - b1	a2 - b2	a3 - b3

_mm_sub_si64

```
__m64 _mm_sub_si64 (__m64 a, __m64 b);
```

Subtracts the signed or unsigned 64-bit integer *b* from the signed or unsigned 64-bit integer *a*.

R
a - b

_mm_sub_epi64

```
__m128i _mm_sub_epi64(__m128i a, __m128i b);
```

Subtracts the two signed or unsigned 64-bit integers in *b* from the two signed or unsigned 64-bit integers in *a*.

R0	R1
a0 - b0	a1 - b1

_mm_subs_epi8

```
__m128i _mm_subs_epi8(__m128i a, __m128i b);
```

Subtracts the 16 signed 8-bit integers of *b* from the 16 signed 8-bit integers of *a* using saturating arithmetic.

R0	R1	...	R15
SignedSaturate (a0 - b0)	SignedSaturate (a1 - b1)	...	SignedSaturate (a15 - b15)

_mm_subs_epi16

```
__m128i _mm_subs_epi16(__m128i a, __m128i b);
```

Subtracts the eight signed 16-bit integers of *b* from the eight signed 16-bit integers of *a* using saturating arithmetic.

R0	R1	...	R15
SignedSaturate (a0 - b0)	SignedSaturate (a1 - b1)	...	SignedSaturate (a7 - b7)

_mm_subs_epu8

```
__m128i _mm_subs_epu8(__m128i a, __m128i b);
```

Subtracts the 16 unsigned 8-bit integers of *b* from the 16 unsigned 8-bit integers of *a* using saturating arithmetic.

R0	R1	...	R15
UnsignedSaturate (a0 - b0)	UnsignedSaturate (a1 - b1)	...	UnsignedSaturate (a15 - b15)

_mm_subs_epu16

```
__m128i _mm_subs_epu16(__m128i a, __m128i b);
```

Subtracts the eight unsigned 16-bit integers of *b* from the eight unsigned 16-bit integers of *a* using saturating arithmetic.

R0	R1	...	R7
UnsignedSaturate (a0 - b0)	UnsignedSaturate (a1 - b1)	...	UnsignedSaturate (a7 - b7)

Logical Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer logical operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in register `R`. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic.

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_and_si128`	Computes AND	`PAND`
`_mm_andnot_si128`	Computes AND and NOT	`PANDN`
`_mm_or_si128`	Computes OR	`POR`
`_mm_xor_si128`	Computes XOR	`PXOR`

_mm_and_si128

```
__m128i _mm_and_si128(__m128i a, __m128i b);
```

Computes the bitwise AND of the 128-bit value in *a* and the 128-bit value in *b*.

R0
`a & b`

_mm_andnot_si128

```
__m128i _mm_andnot_si128(__m128i a, __m128i b);
```

Computes the bitwise AND of the 128-bit value in *b* and the bitwise NOT of the 128-bit value in *a*.

R0
`(~a) & b`

_mm_or_si128

```
__m128i _mm_or_si128(__m128i a, __m128i b);
```

Computes the bitwise OR of the 128-bit value in *a* and the 128-bit value in *b*.

R0
`a | b`

_mm_xor_si128

```
__m128i _mm_xor_si128(__m128i a, __m128i b);
```

Computes the bitwise XOR of the 128-bit value in *a* and the 128-bit value in *b*.

R0
`a ^ b`

Shift Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer shift operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. `R`, `R0`, `R1`...`R7` represent the registers in which results are placed.

NOTE
The `count` argument is one shift count that applies to all elements of the operand being shifted. It is not a vector shift count that shifts each element by a different amount.

Intrinsic	Operation	Shift Type	Corresponding Intel® SSE2 Instruction
`_mm_slli_si128`	Shift left	Logical	`PSLLDQ`
`_mm_slli_epi16`	Shift left	Logical	`PSLLW`
`_mm_sll_epi16`	Shift left	Logical	`PSLLW`
`_mm_slli_epi32`	Shift left	Logical	`PSLLD`
`_mm_sll_epi32`	Shift left	Logical	`PSLLD`
`_mm_slli_epi64`	Shift left	Logical	`PSLLQ`
`_mm_sll_epi64`	Shift left	Logical	`PSLLQ`
`_mm_srai_epi16`	Shift right	Arithmetic	`PSRAW`
`_mm_sra_epi16`	Shift right	Arithmetic	`PSRAW`
`_mm_srai_epi32`	Shift right	Arithmetic	`PSRAD`
`_mm_sra_epi32`	Shift right	Arithmetic	`PSRAD`
`_mm_srli_si128`	Shift right	Logical	`PSRLDQ`
`_mm_srli_epi16`	Shift right	Logical	`PSRLW`
`_mm_srl_epi16`	Shift right	Logical	`PSRLW`
`_mm_srli_epi32`	Shift right	Logical	`PSRLD`
`_mm_srl_epi32`	Shift right	Logical	`PSRLD`
`_mm_srli_epi64`	Shift right	Logical	`PSRLQ`
`_mm_srl_epi64`	Shift right	Logical	`PSRLQ`

_mm_slli_si128

`__m128i _mm_slli_si128(__m128i a, int imm);`

Shifts the 128-bit value in *a* left by *imm* bytes while shifting in zeros. *imm* must be an immediate.

R
a << (imm * 8)

_mm_slli_epi16

`__m128i _mm_slli_epi16(__m128i a, int count);`

Shifts the eight signed or unsigned 16-bit integers in *a* left by count bits while shifting in zeros.

R0	R1	...	R7
`a0 << count`	`a1 << count`	...	`a7 << count`

_mm_sll_epi16

`__m128i _mm_sll_epi16(__m128i a, __m128i count);`

Shifts the eight signed or unsigned 16-bit integers in *a* left by *count* bits while shifting in zeros.

R0	R1	...	R7
`a0 << count`	`a1 << count`	...	`a7 << count`

_mm_slli_epi32

`__m128i _mm_slli_epi32(__m128i a, int count);`

Shifts the four signed or unsigned 32-bit integers in *a* left by *count* bits while shifting in zeros.

R0	R1	R2	R3
`a0 << count`	`a1 << count`	`a2 << count`	`a3 << count`

_mm_sll_epi32

`__m128i _mm_sll_epi32(__m128i a, __m128i count);`

Shifts the four signed or unsigned 32-bit integers in *a* left by *count* bits while shifting in zeros.

R0	R1	R2	R3
`a0 << count`	`a1 << count`	`a2 << count`	`a3 << count`

_mm_slli_epi64

`__m128i _mm_slli_epi64(__m128i a, int count);`

Shifts the two signed or unsigned 64-bit integers in *a* left by *count* bits while shifting in zeros.

R0	R1
a0 << count	a1 << count

_mm_sll_epi64

```
__m128i _mm_sll_epi64(__m128i a, __m128i count);
```

Shifts the two signed or unsigned 64-bit integers in *a* left by *count* bits while shifting in zeros.

R0	R1
a0 << count	a1 << count

_mm_srai_epi16

```
__m128i _mm_srai_epi16(__m128i a, int count);
```

Shifts the eight signed 16-bit integers in *a* right by *count* bits while shifting in the sign bit.

R0	R1	...	R7
a0 >> count	a1 >> count	...	a7 >> count

_mm_sra_epi16

```
__m128i _mm_sra_epi16(__m128i a, __m128i count);
```

Shifts the eight signed 16-bit integers in *a* right by *count* bits while shifting in the sign bit.

R0	R1	...	R7
a0 >> count	a1 >> count	...	a7 >> count

_mm_srai_epi32

```
__m128i _mm_srai_epi32(__m128i a, int count);
```

Shifts the four signed 32-bit integers in *a* right by *count* bits while shifting in the sign bit.

R0	R1	R2	R3
a0 >> count	a1 >> count	a2 >> count	a3 >> count

_mm_sra_epi32

```
__m128i _mm_sra_epi32(__m128i a, __m128i count);
```

Shifts the four signed 32-bit integers in *a* right by *count* bits while shifting in the sign bit.

R0	R1	R2	R3
a0 >> count	a1 >> count	a2 >> count	a3 >> count

_mm_srli_si128

```
__m128i _mm_srli_si128(__m128i a, int imm);
```

Shifts the 128-bit value in *a* right by *imm* bytes while shifting in zeros. *imm* must be an immediate.

R
`srl(a, imm*8)`

_mm_srli_epi16

```
__m128i _mm_srli_epi16(__m128i a, int count);
```

Shifts the eight signed or unsigned 16-bit integers in *a* right by *count* bits while shifting in zeros.

R0	R1	...	R7
`srl(a0, count)`	`srl(a1, count)`	...	`srl(a7, count)`

_mm_srl_epi16

```
__m128i _mm_srl_epi16(__m128i a, __m128i count);
```

Shifts the eight signed or unsigned 16-bit integers in *a* right by `count` bits while shifting in zeros.

R0	R1	...	R7
`srl(a0, count)`	`srl(a1, count)`	...	`srl(a7, count)`

_mm_srli_epi32

```
__m128i _mm_srli_epi32(__m128i a, int count);
```

Shifts the four signed or unsigned 32-bit integers in *a* right by *count* bits while shifting in zeros.

R0	R1	R2	R3
`srl(a0, count)`	`srl(a1, count)`	`srl(a2, count)`	`srl(a3, count)`

_mm_srl_epi32

```
__m128i _mm_srl_epi32(__m128i a, __m128i count);
```

Shifts the four signed or unsigned 32-bit integers in *a* right by *count* bits while shifting in zeros.

R0	R1	R2	R3
`srl(a0, count)`	`srl(a1, count)`	`srl(a2, count)`	`srl(a3, count)`

_mm_srli_epi64

```
__m128i _mm_srli_epi64(__m128i a, int count)
```

Shifts the two signed or unsigned 64-bit integers in *a* right by *count* bits while shifting in zeros.

R0	R1
`srl(a0, count)`	`srl(a1, count)`

_mm_srl_epi64

```
__m128i _mm_srl_epi64(__m128i a, __m128i count)
```

Shifts the two signed or unsigned 64-bit integers in *a* right by *count* bits while shifting in zeros.

R0	R1
`srl(a0, count)`	`srl(a1, count)`

Compare Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer comparison operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. `R`, `R0`, `R1`, ...,`R15` represent the registers in which results are placed.

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_cmpeq_epi8`	Equality	`PCMPEQB`
`_mm_cmpeq_epi16`	Equality	`PCMPEQW`
`_mm_cmpeq_epi32`	Equality	`PCMPEQD`
`_mm_cmpgt_epi8`	Greater Than	`PCMPGTB`
`_mm_cmpgt_epi16`	Greater Than	`PCMPGTW`
`_mm_cmpgt_epi32`	Greater Than	`PCMPGTD`
`_mm_cmplt_epi8`	Less Than	`PCMPGTBr`
`_mm_cmplt_epi16`	Less Than	`PCMPGTWr`
`_mm_cmplt_epi32`	Less Than	`PCMPGTDr`

_mm_cmpeq_epi8

```
__m128i _mm_cmpeq_epi8(__m128i a, __m128i b);
```

Compares the 16 signed or unsigned 8-bit integers in *a* and the 16 signed or unsigned 8-bit integers in *b* for equality.

R0	R1	...	R15
`(a0 == b0) ? 0xff : 0x0`	`(a1 == b1) ? 0xff : 0x0`	...	`(a15 == b15) ? 0xff : 0x0`

_mm_cmpeq_epi16

```
__m128i _mm_cmpeq_epi16(__m128i a, __m128i b);
```

Compares the eight signed or unsigned 16-bit integers in *a* and the eight signed or unsigned 16-bit integers in *b* for equality.

R0	R1	...	R7
`(a0 == b0) ? 0xffff : 0x0`	`(a1 == b1) ? 0xffff : 0x0`	...	`(a7 == b7) ? 0xffff : 0x0`

_mm_cmpeq_epi32

```
__m128i _mm_cmpeq_epi32(__m128i a, __m128i b);
```

Compares the four signed or unsigned 32-bit integers in *a* and the four signed or unsigned 32-bit integers in *b* for equality.

R0	R1	R2	R3
`(a0 == b0) ? 0xffffffff : 0x0`	`(a1 == b1) ? 0xffffffff : 0x0`	`(a2 == b2) ? 0xffffffff : 0x0`	`(a3 == b3) ? 0xffffffff : 0x0`

_mm_cmpgt_epi8

```
__m128i _mm_cmpgt_epi8(__m128i a, __m128i b);
```

Compares the 16 signed 8-bit integers in *a* and the 16 signed 8-bit integers in *b* for greater than.

R0	R1	...	R15
`(a0 > b0) ? 0xff : 0x0`	`(a1 > b1) ? 0xff : 0x0`	...	`(a15 > b15) ? 0xff : 0x0`

_mm_cmpgt_epi16

```
__m128i _mm_cmpgt_epi16(__m128i a, __m128i b);
```

Compares the eight signed 16-bit integers in *a* and the eight signed 16-bit integers in *b* for greater than.

R0	R1	...	R7
`(a0 > b0) ? 0xffff : 0x0`	`(a1 > b1) ? 0xffff : 0x0`	...	`(a7 > b7) ? 0xffff : 0x0`

_mm_cmpgt_epi32

```
__m128i _mm_cmpgt_epi32(__m128i a, __m128i b);
```

Compares the four signed 32-bit integers in *a* and the four signed 32-bit integers in *b* for greater than.

R0	R1	R2	R3
`(a0 > b0) ? 0xffffffff : 0x0`	`(a1 > b1) ? 0xffffffff : 0x0`	`(a2 > b2) ? 0xffffffff : 0x0`	`(a3 > b3) ? 0xffffffff : 0x0`

_mm_cmplt_epi8

```
__m128i _mm_cmplt_epi8( __m128i a, __m128i b);
```

Compares the 16 signed 8-bit integers in *a* and the 16 signed 8-bit integers in *b* for less than.

R0	R1	...	R15
`(a0 < b0) ? 0xff : 0x0`	`(a1 < b1) ? 0xff : 0x0`	...	`(a15 < b15) ? 0xff : 0x0`

_mm_cmplt_epi16

```
__m128i _mm_cmplt_epi16( __m128i a, __m128i b);
```

Compares the eight signed 16-bit integers in *a* and the eight signed 16-bit integers in *b* for less than.

R0	R1	...	R7
`(a0 < b0) ? 0xffff : 0x0`	`(a1 < b1) ? 0xffff : 0x0`	...	`(a7 < b7) ? 0xffff : 0x0`

_mm_cmplt_epi32

```
__m128i _mm_cmplt_epi32( __m128i a, __m128i b);
```

Compares the four signed 32-bit integers in *a* and the four signed 32-bit integers in *b* for less than.

R0	R1	R2	R3
`(a0 < b0) ? 0xffffffff : 0x0`	`(a1 < b1) ? 0xffffffff : 0x0`	`(a2 < b2) ? 0xffffffff : 0x0`	`(a3 < b3) ? 0xffffffff : 0x0`

Conversion Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer conversion operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. `R`, `R0`, `R1`, `R2`, and `R3` represent the registers in which results are placed.

Intrinsics marked with * are implemented only on Intel® 64 architecture. The rest of the intrinsics are implemented on both IA-32 and Intel® 64 architectures.

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_cvtsi64_sd*`	Convert and pass through	`CVTSI2SD`
`_mm_cvtsd_si64*`	Convert according to rounding	`CVTSD2SI`
`_mm_cvttsd_si64*`	Convert using truncation	`CVTTSD2SI`
`_mm_cvtepi32_ps`	Convert to SP FP	None
`_mm_cvtps_epi32`	Convert from SP FP	None
`_mm_cvttps_epi32`	Convert from SP FP using truncate	None

_mm_cvtsi64_sd

```
__m128d _mm_cvtsi64_sd(__m128d a, __int64 b);
```

Converts the signed 64-bit integer value in *b* to a DP FP value. The upper DP FP value in *a* is passed through.

> **NOTE**
> Use only on Intel® 64 architectures.

R0	R1
`(double)b`	`a1`

_mm_cvtsd_si64

```
__int64 _mm_cvtsd_si64(__m128d a);
```

Converts the lower DP FP value of *a* to a 64-bit signed integer value according to the current rounding mode.

> **NOTE**
> Use only on Intel® 64 architectures.

R
`(__int64) a0`

_mm_cvttsd_si64

```
__int64 _mm_cvttsd_si64(__m128d a);
```

Converts the lower DP FP value of *a* to a 64-bit signed integer value using truncation.

> **NOTE**
> Use only on Intel® 64 architectures.

R
`(__int64) a0`

_mm_cvtepi32_ps

```
__m128 _mm_cvtepi32_ps(__m128i a);
```

Converts the four signed 32-bit integer values of *a* to SP FP values.

R0	R1	R2	R3
`(float) a0`	`(float) a1`	`(float) a2`	`(float) a3`

_mm_cvtps_epi32

```
__m128i _mm_cvtps_epi32(__m128 a);
```

Converts the four SP FP values of *a* to signed 32-bit integer values.

R0	R1	R2	R3
`(int) a0`	`(int) a1`	`(int) a2`	`(int) a3`

_mm_cvttps_epi32

```
__m128i _mm_cvttps_epi32(__m128 a);
```

Converts the four SP FP values of *a* to signed 32 bit integer values using truncate.

R0	R1	R2	R3
`(int) a0`	`(int) a1`	`(int) a2`	`(int) a3`

Move Intrinsics

The Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer move operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. `R`, `R0`, `R1`, `R2` and `R3` represent the registers in which results are placed.

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_cvtsi32_si128`	Move and zero	`MOVD`
`_mm_cvtsi64_si128`	Move and zero	`MOVQ`
`_mm_cvtsi128_si32`	Move lowest 32 bits	`MOVD`
`_mm_cvtsi128_si64`	Move lowest 64 bits	`MOVQ`

_mm_cvtsi32_si128

`__m128i _mm_cvtsi32_si128(int a);`

Moves 32-bit integer *a* to the least significant 32 bits of an `__m128i` object. Zeroes the upper 96 bits of the `__m128i` object.

R0	R1	R2	R3
a	0x0	0x0	0x0

_mm_cvtsi64_si128

`__m128i _mm_cvtsi64_si128(__int64 a);`

Moves 64-bit integer *a* to the lower 64 bits of an `__m128i` object, zeroing the upper bits.

R0	R1
a	0x0

_mm_cvtsi128_si32

`int _mm_cvtsi128_si32(__m128i a);`

Moves the least significant 32 bits of *a* to a 32-bit integer.

R
a0

_mm_cvtsi128_si64

`__int64 _mm_cvtsi128_si64(__m128i a);`

Moves the lower 64 bits of *a* to a 64-bit integer.

R
a0

Load Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer load operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. `R`, `R0`, and `R1` represent the registers in which results are placed.

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_load_si128`	Load	`MOVDQA`

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
_mm_loadu_si128	Load	MOVDQU
_mm_loadl_epi64	Load and zero	MOVQ

_mm_load_si128

`__m128i _mm_load_si128(__m128i const*p);`

Loads 128-bit value. Address *p* must be 16-byte aligned.

R
*p

_mm_loadu_si128

`__m128i _mm_loadu_si128(__m128i const*p);`

Loads 128-bit value. Address *p* not need be 16-byte aligned.

R
*p

_mm_loadl_epi64

`__m128i _mm_loadl_epi64(__m128i const*p);`

Load the lower 64 bits of the value pointed to by *p* into the lower 64 bits of the result, zeroing the upper 64 bits of the result.

R0	R1
*p[63:0]	0x0

Set Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer set operations are listed in this topic. These intrinsics are composite intrinsics because they require more than one instruction to implement them. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. `R`, `R0`, `R1`...`R15` represent the registers in which results are placed.

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
_mm_set_epi64	Set two integer values	Composite

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_set_epi64x`	Set two integer values	`Composite`
`_mm_set_epi32`	Set four integer values	`Composite`
`_mm_set_epi16`	Set eight integer values	`Composite`
`_mm_set_epi8`	Set sixteen integer values	`Composite`
`_mm_set1_epi64`	Set two integer values	`Composite`
`_mm_set1_epi64x`	Set two integer values	`Composite`
`_mm_set1_epi32`	Set four integer values	`Composite`
`_mm_set1_epi16`	Set eight integer values	`Composite`
`_mm_set1_epi8`	Set sixteen integer values	`Composite`
`_mm_setr_epi64`	Set two integer values in reverse order	`Composite`
`_mm_setr_epi32`	Set four integer values in reverse order	`Composite`
`_mm_setr_epi16`	Set eight integer values in reverse order	`Composite`
`_mm_setr_epi8`	Set sixteen integer values in reverse order	`Composite`
`_mm_setzero_si128`	Set to zero	`Composite`

_mm_set_epi64

```
__m128i _mm_set_epi64(__m64 q1, __m64 q0);
```

Sets the two 64-bit integer values.

R0	R1
`q0`	`q1`

_mm_set_epi64x

```
__m128i _mm_set_epi64x(__int64 b, __int64 a);
```

Sets the two 64-bit integer values.

R0	R1
`a`	`b`

_mm_set_epi32

```
__m128i _mm_set_epi32(int i3, int i2, int i1, int i0);
```

Sets the four signed 32-bit integer values.

R0	R1	R2	R3
i0	i1	i2	i3

_mm_set_epi16

```
__m128i _mm_set_epi16(short w7, short w6, short w5, short w4, short w3, short w2, short
w1, short w0);
```

Sets the eight signed 16-bit integer values.

R0	R1	...	R7
w0	w1	...	w7

_mm_set_epi8

```
__m128i _mm_set_epi8(char b15, char b14, char b13, char b12, char b11, char b10, char
b9, char b8, char b7, char b6, char b5, char b4, char b3, char b2, char b1, char b0);
```

Sets the 16 signed 8-bit integer values.

R0	R1	...	R15
b0	b1	...	b15

_mm_set1_epi64

```
__m128i _mm_set1_epi64(__m64 q);
```

Sets the two 64-bit integer values to *q*.

R0	R1
q	q

_mm_set1_epi64x

```
__m128i _mm_set1_epi64x(__int64 a);
```

Sets the two 64-bit integer values to *a*.

R0	R1
a	a

_mm_set1_epi32

```
__m128i _mm_set1_epi32(int i);
```

Sets the four signed 32-bit integer values to *i*.

R0	R1	R2	R3
i	i	i	i

_mm_set1_epi16

```
__m128i _mm_set1_epi16(short w);
```

Sets the eight signed 16-bit integer values to *w*.

R0	R1	...	R7
w	w	w	w

_mm_set1_epi8

```
__m128i _mm_set1_epi8(char b);
```

Sets the 16 signed 8-bit integer values to *b*.

R0	R1	...	R15
b	b	b	b

_mm_setr_epi64

```
__m128i _mm_setr_epi64(__m64 q0, __m64 q1);
```

Sets the two 64-bit integer values in reverse order.

R0	R1
q0	q1

_mm_setr_epi32

```
__m128i _mm_setr_epi32(int i0, int i1, int i2, int i3);
```

Sets the four signed 32-bit integer values in reverse order.

R0	R1	R2	R3
i0	i1	i2	i3

_mm_setr_epi16

```
__m128i _mm_setr_epi16(short w0, short w1, short w2, short w3, short w4, short w5,
short w6, short w7);
```

Sets the eight signed 16-bit integer values in reverse order.

R0	R1	...	R7
w0	w1	...	w7

_mm_setr_epi8

```
__m128i _mm_setr_epi8(char b0, char b1, char b2, char b3, char b4, char b5, char b6,
char b7, char b8, char b9, char b10, char b11, char b12, char b13, char b14, char b15);
```

Sets the 16 signed 8-bit integer values in reverse order.

R0	R1	...	R15
b0	b1	...	b15

_mm_setzero_si128

```
__m128i _mm_setzero_si128();
```

Sets the 128-bit value to zero.

R
0x0

Store Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for integer store operations are listed in this topic. The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The detailed description of each intrinsic contains a table detailing the returns. In these tables, *p* is an access to the result.

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
_mm_stream_si128	Store	MOVNTDQ
_mm_stream_si32	Store	MOVNTI
_mm_store_si128	Store	MOVDQA
_mm_storeu_si128	Store	MOVDQU
_mm_maskmoveu_si128	Conditional store	MASKMOVDQU
_mm_storel_epi64	Store lowest	MOVQ

_mm_stream_si128

```
void _mm_stream_si128(__m128i *p, __m128i a);
```

Stores the data in *a* to the address *p* without polluting the caches. If the cache line containing address *p* is already in the cache, the cache will be updated. Address *p* must be 16 byte aligned.

*p
a

_mm_stream_si32

```
void _mm_stream_si32(int *p, int a);
```

Stores the data in *a* to the address *p* without polluting the caches. If the cache line containing address *p* is already in the cache, the cache will be updated.

*p
a

_mm_store_si128

```
void _mm_store_si128(__m128i *p, __m128i b);
```

Stores 128-bit value. Address *p* must be 16 byte aligned.

*p
a

_mm_storeu_si128

```
void _mm_storeu_si128(__m128i *p, __m128i b);
```

Stores 128-bit value. Address *p* need not be 16-byte aligned.

*p
a

_mm_maskmoveu_si128

```
void _mm_maskmoveu_si128(__m128i d, __m128i n, char *p);
```

Conditionally store byte elements of *d* to address *p*. The high bit of each byte in the selector *n* determines whether the corresponding byte in *d* will be stored. Address *p* need not be 16-byte aligned.

if (n0[7])	if (n1[7]	...	if (n15[7])
p[0] := d0	p[1] := d1	...	p[15] := d15

_mm_storel_epi64

```
void _mm_storel_epi64(__m128i *p, __m128i a);
```

Stores the lower 64 bits of the value pointed to by *p*.

*p[63:0]
a0

Miscellaneous Functions and Intrinsics

Cacheability Support Intrinsics

The prototypes for Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for cacheability support are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® SSE2 Instruction
`_mm_stream_pd`	Store	`MOVNTPD`
`_mm256_stream_pd`	Store	`VMOVNTPD`
`_mm_stream_si128`	Store	`MOVNTDQ`
`_mm256_stream_si256`	Store	`VMOVNTDQ`
`_mm_stream_si32`	Store	`MOVNTI`
`_mm_stream_si64*`	Store	`MOVNTI`
`_mm_clflush`	Flush	`CLFLUSH`
`_mm_clflushopt`	Flush	`CLFLUSHOPT`
`_mm_lfence`	Guarantee visibility	`LFENCE`
`_mm_mfence`	Guarantee visibility	`MFENCE`

_mm_stream_pd

```
void _mm_stream_pd(double *p, __m128d a);
```

Stores the data in *a* to the address *p* without polluting caches. The address *p* must be 16-byte (128-bit version) aligned. If the cache line containing address *p* is already in the cache, the cache will be updated. `p[0] := a0 p[1] := a1`

p[0]	p[1]
a0	a1

_mm256_stream_pd

```
void _mm256_stream_pd(double *p, __m256d a);
```

Stores the data in *a* to the address *p* without polluting caches. The address *p* must be 32-byte (VEX.256 encoded version) aligned. If the cache line containing address *p* is already in the cache, the cache will be updated. `p[0] := a0 p[1] := a1`

p[0]	p[1]
a0	a1

_mm_stream_si128

```
void _mm_stream_si128(__m128i *p, __m128i a);
```

Stores the data in *a* to the address *p* without polluting the caches. If the cache line containing address *p* is already in the cache, the cache will be updated. Address *p* must be 16-byte (128-bit version) aligned.

*p
a

_mm256_stream_si256

```
void _mm256_stream_si256(__m256i *p, __m256i a);
```

Stores the data in *a* to the address *p* without polluting the caches. If the cache line containing address *p* is already in the cache, the cache will be updated. Address *p* must be 32-byte (VEX.256 encoded version) aligned.

*p
a

_mm_stream_si32

```
void _mm_stream_si32(int *p, int a);
```

Stores the 32-bit integer data in *a* to the address *p* without polluting the caches. If the cache line containing address *p* is already in the cache, the cache will be updated.

*p
a

_mm_stream_si64

```
void _mm_stream_si64(__int64 *p, __int64 a);
```

Stores the 64-bit integer data in *a* to the address *p* without polluting the caches. If the cache line containing address *p* is already in the cache, the cache is updated.

*p
a

_mm_clflush

```
void _mm_clflush(void const*p);
```

Cache line containing *p* is flushed and invalidated from all caches in the coherency domain.

*p
a

_mm_clflushopt

```
void _mm_clflushopt(void const *p);
```

Cache line containing *p* is flushed and invalidated from all caches in the coherency domain. This optimized version of the _mm_clflush is available if indicated by the CPUID feature flag `CLFLUSHOPT`.

*p
a

_mm_lfence

```
void _mm_lfence(void);
```

Guarantees that every load instruction that precedes, in program order, the load fence instruction is globally visible before any load instruction which follows the fence in program order.

_mm_mfence

```
void _mm_mfence(void);
```

Guarantees that every memory access that precedes, in program order, the memory fence instruction is globally visible before any memory instruction which follows the fence in program order.

Miscellaneous Intrinsics

Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsics for miscellaneous operations are listed in the following table followed by descriptions.

The prototypes for Intel® SSE2 intrinsics are in the `emmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic	Operation	Corresponding Intel® SSE 2 Instruction
_mm_packs_epi16	Packed Saturation	PACKSSWB
_mm_packs_epi32	Packed Saturation	PACKSSDW
_mm_packus_epi16	Packed Saturation	PACKUSWB
_mm_extract_epi16	Extraction	PEXTRW
_mm_insert_epi16	Insertion	PINSRW
_mm_movemask_epi8	Mask Creation	PMOVMSKB
_mm_shuffle_epi32	Shuffle	PSHUFD
_mm_shufflehi_epi16	Shuffle	PSHUFHW
_mm_shufflelo_epi16	Shuffle	PSHUFLW
_mm_unpackhi_epi8	Interleave	PUNPCKHBW
_mm_unpackhi_epi16	Interleave	PUNPCKHWD

Intrinsic	Operation	Corresponding Intel® SSE 2 Instruction
`_mm_unpackhi_epi32`	Interleave	`PUNPCKHDQ`
`_mm_unpackhi_epi64`	Interleave	`PUNPCKHQDQ`
`_mm_unpacklo_epi8`	Interleave	`PUNPCKLBW`
`_mm_unpacklo_epi16`	Interleave	`PUNPCKLWD`
`_mm_unpacklo_epi32`	Interleave	`PUNPCKLDQ`
`_mm_unpacklo_epi64`	Interleave	`PUNPCKLQDQ`
`_mm_movepi64_pi64`	Move	`MOVDQ2Q`
`_mm_movpi64_epi64`	Move	`MOVDQ2Q`
`_mm_move_epi64`	Move	`MOVQ`

`_mm_unpacklo_pd`	Interleave	`UNPCKLPD`
`_mm_movemask_pd`	Create mask	`MOVMSKPD`
`_mm_shuffle_pd`	Select values	`SHUFPD`

_mm_packs_epi16

```
__m128i _mm_packs_epi16(__m128i a, __m128i b);
```

Packs the 16 signed 16-bit integers from *a* and *b* into 8-bit integers and saturates.

R0	...	R7	R8	...	R15
`Signed Saturate(a0)`	`...`	`Signed Saturate(a7)`	`Signed Saturate(b0)`	`...`	`Signed Saturate(b7)`

_mm_packs_epi32

```
__m128i _mm_packs_epi32(__m128i a, __m128i b);
```

Packs the eight signed 32-bit integers from *a* and *b* into signed 16-bit integers and saturates.

R0	...	R3	R4	...	R7
`Signed Saturate(a0)`	`...`	`Signed Saturate(a3)`	`Signed Saturate(b0)`	`...`	`Signed Saturate(b3)`

_mm_packus_epi16

```
__m128i _mm_packus_epi16(__m128i a, __m128i b);
```

Packs the 16 signed 16-bit integers from *a* and *b* into 8-bit unsigned integers and saturates.

R0	...	R7	R8	...	R15
Unsigned Saturate(a0)	...	Unsigned Saturate(a7)	Unsigned Saturate(b0)	...	Unsigned Saturate(b15)

_mm_extract_epi16

```
int _mm_extract_epi16(__m128i a, int imm);
```

Extracts the selected signed or unsigned 16-bit integer from *a* and zero extends. The selector *imm* must be an immediate.

R0
(imm == 0) ? a0: ((imm == 1) ? a1: ... (imm==7) ? a7)

_mm_insert_epi16

```
__m128i _mm_insert_epi16(__m128i a, int b, int imm);
```

Inserts the least significant 16 bits of *b* into the selected 16-bit integer of *a*. The selector *imm* must be an immediate.

R0	R1	...	R7
(imm == 0) ? b : a0;	(imm == 1) ? b : a1;	...	(imm == 7) ? b : a7;

_mm_movemask_epi8

```
int _mm_movemask_epi8(__m128i a);
```

Creates a 16-bit mask from the most significant bits of the 16 signed or unsigned 8-bit integers in *a* and zero extends the upper bits.

R0
a15[7] << 15 | a14[7] << 14 | ... a1[7] << 1 | a0[7]

_mm_shuffle_epi32

```
__m128i _mm_shuffle_epi32(__m128i a, int imm);
```

Shuffles the four signed or unsigned 32-bit integers in *a* as specified by *imm*. The shuffle value, *imm*, must be an immediate. See Macro Function for Shuffle for a description of shuffle semantics.

_mm_shufflehi_epi16

```
__m128i _mm_shufflehi_epi16(__m128i a, int imm);
```

Shuffles the upper four signed or unsigned 16-bit integers in *a* as specified by *imm*. The shuffle value, *imm*, must be an immediate. See Macro Function for Shuffle for a description of shuffle semantics.

_mm_shufflelo_epi16

```
__m128i _mm_shufflelo_epi16(__m128i a, int imm);
```

Shuffles the lower four signed or unsigned 16-bit integers in *a* as specified by *imm*. The shuffle value, *imm*, must be an immediate. See Macro Function for Shuffle for a description of shuffle semantics.

_mm_unpackhi_epi8

```
__m128i _mm_unpackhi_epi8(__m128i a, __m128i b);
```

Interleaves the upper eight signed or unsigned 8-bit integers in *a* with the upper eight signed or unsigned 8-bit integers in *b*.

R0	R1	R2	R3	...	R14	R15
a8	b8	a9	b9	...	a15	b15

_mm_unpackhi_epi16

```
__m128i _mm_unpackhi_epi16(__m128i a, __m128i b);
```

Interleaves the upper four signed or unsigned 16-bit integers in *a* with the upper four signed or unsigned 16-bit integers in *b*.

R0	R1	R2	R3	R4	R5	R6	R7
a4	b4	a5	b5	a6	b6	a7	b7

_mm_unpackhi_epi32

```
__m128i _mm_unpackhi_epi32(__m128i a, __m128i b);
```

Interleaves the upper two signed or unsigned 32-bit integers in *a* with the upper two signed or unsigned 32-bit integers in *b*.

R0	R1	R2	R3
a2	b2	a3	b3

_mm_unpackhi_epi64

```
__m128i _mm_unpackhi_epi64(__m128i a, __m128i b);
```

Interleaves the upper signed or unsigned 64-bit integer in *a* with the upper signed or unsigned 64-bit integer in *b*.

R0	R1
a1	b1

_mm_unpacklo_epi8

```
__m128i _mm_unpacklo_epi8(__m128i a, __m128i b);
```

Interleaves the lower eight signed or unsigned 8-bit integers in *a* with the lower eight signed or unsigned 8-bit integers in *b*.

R0	R1	R2	R3	...	R14	R15
a0	b0	a1	b1	...	a7	b7

_mm_unpacklo_epi16

```
__m128i _mm_unpacklo_epi16(__m128i a, __m128i b);
```

Interleaves the lower four signed or unsigned 16-bit integers in *a* with the lower four signed or unsigned 16-bit integers in *b*.

R0	R1	R2	R3	R4	R5	R6	R7
a0	b0	a1	b1	a2	b2	a3	b3

_mm_unpacklo_epi32

```
__m128i _mm_unpacklo_epi32(__m128i a, __m128i b);
```

Interleaves the lower two signed or unsigned 32-bit integers in *a* with the lower two signed or unsigned 32-bit integers in *b*.

R0	R1	R2	R3
a0	b0	a1	b1

_mm_unpacklo_epi64

```
__m128i _mm_unpacklo_epi64(__m128i a, __m128i b);
```

Interleaves the lower signed or unsigned 64-bit integer in *a* with the lower signed or unsigned 64-bit integer in *b*.

R0	R1
a0	b0

_mm_movepi64_pi64

```
__m64 _mm_movepi64_pi64(__m128i a);
```

Returns the lower 64 bits of *a* as an `__m64` type.

R0
a0

_mm_movpi64_pi64

```
__m128i _mm_movpi64_pi64(__m64 a);
```

Moves the 64 bits of *a* to the lower 64 bits of the result, zeroing the upper bits.

R0	R1
a0	0X0

_mm_move_epi64

```
__m128i _mm_move_epi64(__m128i a);
```

Moves the lower 64 bits of *a* to the lower 64 bits of the result, zeroing the upper bits.

R0	R1
a0	0X0

_mm_unpackhi_pd

```
__m128d _mm_unpackhi_pd(__m128d a, __m128d b);
```

Interleaves the upper DP FP values of *a* and *b*.

R0	R1
a1	b1

_mm_unpacklo_pd

```
__m128d _mm_unpacklo_pd(__m128d a, __m128d b);
```

Interleaves the lower DP FP values of *a* and *b*.

R0	R1
a0	b0

_mm_movemask_pd

```
int _mm_movemask_pd(__m128d a);
```

Creates a two-bit mask from the sign bits of the two DP FP values of *a*.

R
sign(a1) << 1 | sign(a0)

_mm_shuffle_pd

```
__m128d _mm_shuffle_pd(__m128d a, __m128d b, int i)
```

Selects two specific DP FP values from *a* and *b*, based on the mask *i*. The mask must be an immediate. See Macro Function for Shuffle for a description of the shuffle semantics.

Casting Support Intrinsics

Intel® C++ Compiler supports casting between various single-precision, double-precision, and integer vector types. These intrinsics do not convert values; they change one data type to another without changing the value.

The intrinsics for casting support do not have any corresponding Intel® Streaming SIMD Extensions 2 (Intel® SSE2) instructions. The syntax for the Casting Support intrinsics are as follows:

`__m128 _mm_castpd_ps(__m128d in);`

`__m128i _mm_castpd_si128(__m128d in);`

`__m128d _mm_castps_pd(__m128 in);`

`__m128i _mm_castps_si128(__m128 in);`

`__m128 _mm_castsi128_ps(__m128i in);`

`__m128d _mm_castsi128_pd(__m128i in);`

Pause Intrinsic

The prototype for this Intel® Streaming SIMD Extensions 2 (Intel® SSE2) intrinsic is in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

`PAUSE` Intrinsic

`void _mm_pause(void);`

The `pause` intrinsic is used in spin-wait loops with the processors implementing dynamic execution (especially out-of-order execution). In the spin-wait loop, the `pause` intrinsic improves the speed at which the code detects the release of the lock and provides especially significant performance gain.

The execution of the next instruction is delayed for an implementation-specific amount of time. The `PAUSE` instruction does not modify the architectural state. For dynamic scheduling, the `PAUSE` instruction reduces the penalty of exiting from the spin-loop.

Example of loop with the PAUSE instruction:

In this example, the program spins until memory location `A` matches the value in register `eax`. The code sequence that follows shows a test-and-test-and-set.

```
spin_loop:pause
cmp eax, A
jne spin_loop
```

In this example, the spin occurs only after the attempt to get a lock has failed.

```
get_lock: mov eax, 1
xchg eax, A ; Try to get lock
cmp eax, 0 ; Test if successful
jne spin_loop
```

Critical Section

```
// critical_section code
mov A, 0 ; Release lock
jmp continue
spin_loop: pause;
// spin-loop hint
cmp 0, A ;
// check lock availability
```

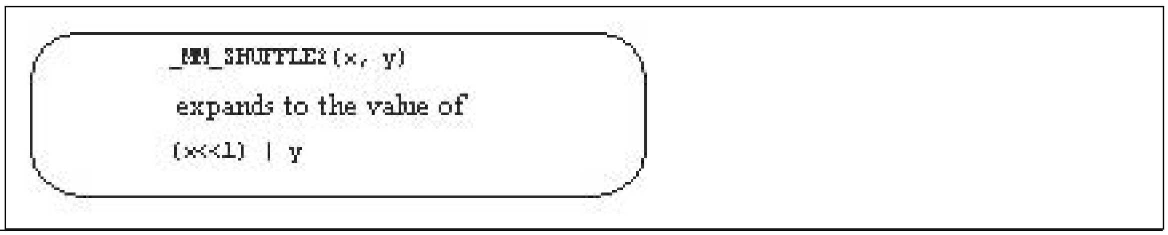
```
jne spin_loop
jmp get_lock
// continue: other code
```

NOTE
The first branch is predicted to fall-through to the critical section in anticipation of successfully gaining access to the lock. It is highly recommended that all spin-wait loops include the `PAUSE` instruction. Since `PAUSE` is backwards compatible to all existing IA-32 architecture-based processor generations, a test for processor type (a CPUID test) is not needed. All legacy processors execute `PAUSE` instruction as a `NOP`, but in processors that use the `PAUSE` instruction as a hint there can be significant performance benefit.

Macro Function for Shuffle

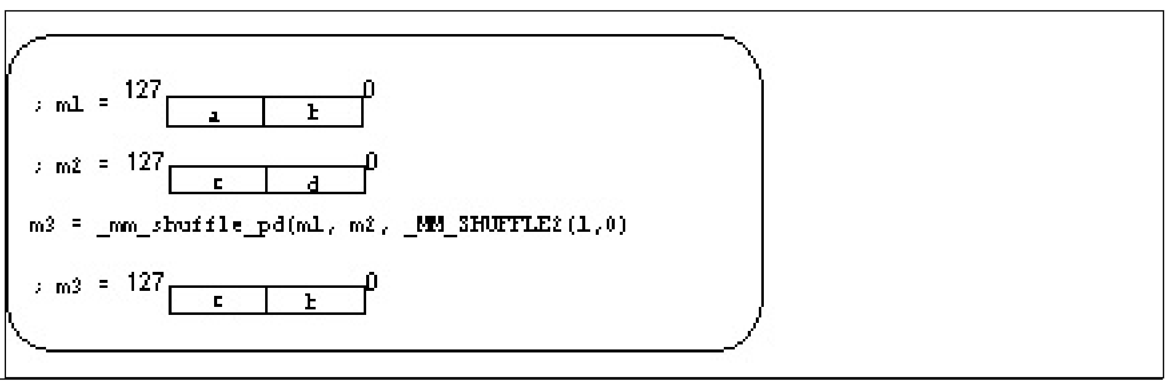
Intel® Streaming SIMD Extensions 2 (Intel® SSE2) provide a macro function to help create constants that describe shuffle operations. The macro takes two small integers (in the range of 0 to 1) and combines them into an 2-bit immediate value used by the `SHUFPD` instruction. See the following example.

Shuffle Function Macro



You can view the two integers as selectors for choosing which two words from the first input operand and which two words from the second are to be put into the result word.

View of Original and Result Words with Shuffle Function Macro



Intrinsics Returning Vectors of Undefined Values

These intrinsics generate vectors of undefined values. The result of the intrinsics is usually used as an argument to another intrinsic that requires all operands to be initialized, and when the content of a particular argument does not matter.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

For example, you can use such an intrinsic when you need to calculate a sum of packed double-precision floating-point values located in the *xmm* register. To avoid unnecessary moves, you can use the following code to obtain the required result at the low 64 bits:

```
__m128d HILO    = doSomeWork();
__m128d HI = _mm_unpackhi_pd(HILO, _mm_undefined_pd());
__m128d result    = _mm_add_sd(HI, HILO);
```

_mm_undefined_pd

`extern __m128d _mm_undefined_pd(void);`

Returns a vector of two double precision floating point elements. The content of the vector is not specified.

_mm_undefined_si128

`extern __m128i _mm_undefined_si128(void);`

Returns a vector of four packed doubleword integer elements. The content of the vector is not specified.

See Also

_mm256_undefined_si128() Returns a vector of eight packed doubleword integer elements. No corresponding Intel® AVX instruction.

_mm256_undefined_pd() Returns a vector of four double precision floating point elements. No corresponding Intel® AVX instruction.

Intrinsics for Intel® Streaming SIMD Extensions (Intel® SSE)

This section describes the C++ language-level features supporting the Intel® Streaming SIMD Extensions (Intel® SSE) in the Intel® C++ Compiler Classic. The prototypes for Intel® SSE intrinsics are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The following topics summarize these intrinsics.

Details about Intel® Streaming SIMD Extensions Intrinsics

Intel® Streaming SIMD Extensions (Intel® SSE) instructions use the following features:

- Registers – Enable packed data of up to 128 bits in length for optimal SIMD processing
- Data Types – Enable packing of up to 16 elements of data in one register

Registers

Intel® Streaming SIMD Extensions use eight 128-bit registers (`XMM0` to `XMM7`).

Because each of these registers can hold more than one data element, the processor can process more than one data element simultaneously. This processing capability is also known as single-instruction multiple data processing (SIMD).

For each computational and data manipulation instruction in the new extension sets, there is a corresponding C intrinsic that implements that instruction directly. This frees you from managing registers and assembly programming. Further, the compiler optimizes the instruction scheduling so that your executable runs faster.

NOTE
The MM and XMM registers are the SIMD registers used by the systems based on IA-32 architecture to implement MMX™ technology and Intel® SSE or Intel® Streaming SIMD Extensions 2 (Intel® SSE2).

Data Types

These intrinsic functions use four new C data types as operands, representing the new registers that are used as the operands to these intrinsic functions.

New Data Types

The following table details for which instructions each of the new data types are available.

New Data Type	Intel® Streaming SIMD Extensions Intrinsics	Intel® Streaming SIMD Extensions 2 Intrinsics	Intel® Streaming SIMD Extensions 3 Intrinsics
__m64	Available	Available	Available
__m128	Available	Available	Available
__m128d	Not available	Available	Available
__m128i	Not available	Available	Available

__m128 Data Types

The __m128 data type is used to represent the contents of a Intel® SSE register used by Intel® SSE intrinsics. The __m128 data type can hold four 32-bit floating-point values.

The __m128d data type can hold two 64-bit floating-point values.

The __m128i data type can hold sixteen 8-bit, eight 16-bit, four 32-bit, or two 64-bit integer values.

The compiler aligns __m128d and __m128ilocal and global data to 16-byte boundaries on the stack. To align integer, float, or double arrays, you can use the __declspec(align) statement.

Data Types Usage Guidelines

These data types are not basic ANSI C data types. You must observe the following usage restrictions:

- Use data types only on either side of an assignment, as a return value, or as a parameter. You cannot use it with other arithmetic expressions (+, -, etc).
- Use data types as objects in aggregates, such as unions, to access the byte elements and structures.
- Use data types only with the respective intrinsics described in this documentation.

Accessing __m128i Data

To access 8-bit data:

```
#define  _mm_extract_epi8(x, imm) \
((((imm) & 0x1) == 0) ?   \
 _mm_extract_epi16((x), (imm) >> 1) & 0xff : \
 _mm_extract_epi16( _mm_srli_epi16((x), 8), (imm) >> 1))
```

For 16-bit data, use the following intrinsic:

```
int  _mm_extract_epi16(__m128i a, int imm)
```

To access 32-bit data:

```
#define _mm_extract_epi32(x, imm) \
 _mm_cvtsi128_si32( _mm_srli_si128((x), 4 * (imm)))
```

`__declspec(align)` declaration

Writing Programs with Intel® Streaming SIMD Extensions (Intel® SSE) Intrinsics

You should be familiar with the hardware features provided by Intel® Streaming SIMD Extensions (Intel® SSE) when writing programs with the intrinsics. The following are four important issues to keep in mind:

- Certain intrinsics, such as `_mm_loadr_ps` and `_mm_cmpgt_ss`, are not directly supported by the instruction set. While these intrinsics are convenient programming aids, be mindful that they may consist of more than one machine-language instruction.
- Floating-point data loaded or stored as `__m128` objects must be generally 16-byte-aligned.
- Some intrinsics require that their argument be immediates, that is, constant integers (literals), due to the nature of the instruction.
- The result of arithmetic operations acting on two `NaN` (Not a Number) arguments is undefined. Therefore, FP operations using `NaN` arguments will not match the expected behavior of the corresponding assembly instructions.

Arithmetic Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for arithmetic operations are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in a register. This register is illustrated for each intrinsic with R0-R3. R0, R1, R2, and R3 each represent one of the four 32-bit pieces of the result register.

Intrinsic Name	Operation	Corresponding Intel® SSE Instruction
`_mm_add_ss`	Addition	`ADDSS`
`_mm_add_ps`	Addition	`ADDPS`
`_mm_sub_ss`	Subtraction	`SUBSS`
`_mm_sub_ps`	Subtraction	`SUBPS`
`_mm_mul_ss`	Multiplication	`MULSS`
`_mm_mul_ps`	Multiplication	`MULPS`
`_mm_div_ss`	Division	`DIVSS`
`_mm_div_ps`	Division	`DIVPS`
`_mm_sqrt_ss`	Squared Root	`SQRTSS`

Intrinsic Name	Operation	Corresponding Intel® SSE Instruction
`_mm_sqrt_ps`	Squared Root	`SQRTPS`
`_mm_rcp_ss`	Reciprocal	`RCPSS`
`_mm_rcp_ps`	Reciprocal	`RCPPS`
`_mm_rsqrt_ss`	Reciprocal Squared Root	`RSQRTSS`
`_mm_rsqrt_ps`	Reciprocal Squared Root	`RSQRTPS`
`_mm_min_ss`	Computes Minimum	`MINSS`
`_mm_min_ps`	Computes Minimum	`MINPS`
`_mm_max_ss`	Computes Maximum	`MAXSS`
`_mm_max_ps`	Computes Maximum	`MAXPS`

_mm_add_ss

```
__m128 _mm_add_ss(__m128 a, __m128 b);
```

Adds the lower single-precision, floating-point (FP) values of *a* and *b*; the upper three single-precision FP values are passed through from *a*.

R0	R1	R2	R3
a0 + b0	a1	a2	a3

_mm_add_ps

```
__m128 _mm_add_ps(__m128 a, __m128 b);
```

Adds the four single-precision FP values of *a* and *b*.

R0	R1	R2	R3
a0 +b0	`a1 + b1`	`a2 + b2`	`a3 + b3`

_mm_sub_ss

```
__m128 _mm_sub_ss(__m128 a, __m128 b);
```

Subtracts the lower single-precision FP values of *a* and *b*. The upper three single-precision FP values are passed through from *a*.

R0	R1	R2	R3
a0 - b0	a1	a2	a3

_mm_sub_ps

```
__m128 _mm_sub_ps(__m128 a, __m128 b);
```

Subtracts the four single-precision FP values of *a* and *b*.

R0	R1	R2	R3
a0 - b0	a1 - b1	a2 - b2	a3 - b3

_mm_mul_ss

```
__m128 _mm_mul_ss(__m128 a, __m128 b);
```

Multiplies the lower single-precision FP values of *a* and *b*; the upper three single-precision FP values are passed through from *a*.

R0	R1	R2	R3
a0 * b0	a1	a2	a3

_mm_mul_ps

```
__m128 _mm_mul_ps(__m128 a, __m128 b);
```

Multiplies the four single-precision FP values of *a* and *b*.

R0	R1	R2	R3
a0 * b0	a1 * b1	a2 * b2	a3 * b3

_mm_div_ss

```
__m128 _mm_div_ss(__m128 a, __m128 b);
```

Divides the lower single-precision FP values of *a* and *b*; the upper three single-precision FP values are passed through from *a*.

R0	R1	R2	R3
a0 / b0	a1	a2	a3

_mm_div_ps

```
__m128 _mm_div_ps(__m128 a, __m128 b);
```

Divides the four single-precision FP values of *a* and *b*.

R0	R1	R2	R3
a0 / b0	a1 / b1	a2 / b2	a3 / b3

_mm_sqrt_ss

```
__m128 _mm_sqrt_ss(__m128 a);
```

Computes the square root of the lower single-precision FP value of *a* ; the upper three single-precision FP values are passed through.

R0	R1	R2	R3
`sqrt(a0)`	a1	a2	a3

_mm_sqrt_ps

```
__m128 _mm_sqrt_ps(__m128 a);
```

Computes the square roots of the four single-precision FP values of *a*.

R0	R1	R2	R3
`sqrt(a0)`	`sqrt(a1)`	`sqrt(a2)`	`sqrt(a3)`

_mm_rcp_ss

```
__m128 _mm_rcp_ss(__m128 a);
```

Computes the approximation of the reciprocal of the lower single-precision FP value of *a*; the upper the single-precision FP values are passed through.

R0	R1	R2	R3
`recip(a0)`	a1	a2	a3

_mm_rcp_ps

```
__m128 _mm_rcp_ps(__m128 a);
```

Computes the approximations of reciprocals of the four single-precision FP values of *a*.

R0	R1	R2	R3
`recip(a0)`	`recip(a1)`	`recip(a2)`	`recip(a3)`

_mm_rsqrt_ss

```
__m128 _mm_rsqrt_ss(__m128 a);
```

Computes the approximation of the reciprocal of the square root of the lower single-precision FP value of *a*; the upper three single-precision FP values are passed through.

R0	R1	R2	R3
`recip(sqrt(a0))`	a1	a2	a3

_mm_rsqrt_ps

```
__m128 _mm_rsqrt_ps(__m128 a);
```

Computes the approximations of the reciprocals of the square roots of the four single-precision FP values of *a*.

R0	R1	R2	R3
`recip(sqrt(a0))`	`recip(sqrt(a1))`	`recip(sqrt(a2))`	`recip(sqrt(a3))`

_mm_min_ss

```
__m128 _mm_min_ss(__m128 a, __m128 b);
```

Computes the minimum of the lower single-precision FP values of *a* and *b*; the upper three single-precision FP values are passed through from *a*.

R0	R1	R2	R3
`min(a0, b0)`	a1	a2	a3

_mm_min_ps

```
__m128 _mm_min_ps(__m128 a, __m128 b);
```

Computes the minimum of the four single-precision FP values of *a* and *b*.

R0	R1	R2	R3
`min(a0, b0)`	`min(a1, b1)`	`min(a2, b2)`	`min(a3, b3)`

_mm_max_ss

```
__m128 _mm_max_ss(__m128 a, __m128 b);
```

Computes the maximum of the lower single-precision FP values of *a* and *b*; the upper three single-precision FP values are passed through from *a*.

R0	R1	R2	R3
`max(a0, b0)`	a1	a2	a3

_mm_max_ps

```
__m128 _mm_max_ps(__m128 a, __m128 b);
```

Computes the maximum of the four single-precision FP values of *a* and *b*.

R0	R1	R2	R3
`max(a0, b0)`	`max(a1, b1)`	`max(a2, b2)`	`max(a3, b3)`

Logical Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for logical operations are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in a register. This register is illustrated for each intrinsic with R0-R3. R0, R1, R2, and R3 each represent one of the four 32-bit pieces of the result register.

Intrinsic Name	Operation	Corresponding Intel® SSE Instruction
`_mm_and_ps`	Bitwise AND	`ANDPS`
`_mm_andnot_ps`	Bitwise ANDNOT	`ANDNPS`
`_mm_or_ps`	Bitwise OR	`ORPS`
`_mm_xor_ps`	Bitwise Exclusive OR	`XORPS`

_mm_and_ps

```
__m128 _mm_and_ps(__m128 a, __m128 b);
```

Computes the bitwise AND of the four SP FP values of *a* and *b*.

R0	R1	R2	R3
`a0 & b0`	`a1 & b1`	`a2 & b2`	`a3 & b3`

_mm_andnot_ps

```
__m128 _mm_andnot_ps(__m128 a, __m128 b);
```

Computes the bitwise AND-NOT of the four SP FP values of *a* and *b*.

R0	R1	R2	R3
`~a0 & b0`	`~a1 & b1`	`~a2 & b2`	`~a3 & b3`

_mm_or_ps

```
__m128 _mm_or_ps(__m128 a, __m128 b);
```

Computes the bitwise OR of the four SP FP values of *a* and *b*.

R0	R1	R2	R3
`a0 | b0`	`a1 | b1`	`a2 | b2`	`a3 | b3`

_mm_xor_ps

```
__m128 _mm_xor_ps(__m128 a, __m128 b);
```

Computes bitwise XOR (exclusive-or) of the four SP FP values of *a* and *b*.

R0	R1	R2	R3
`a0 ^ b0`	`a1 ^ b1`	`a2 ^ b2`	`a3 ^ b3`

Compare Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for comparison operations are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Each comparison intrinsic performs a comparison of `a` and `b`. For the packed form, the four single-precision FP values of *a* and *b* are compared, and a 128-bit mask is returned. For the scalar form, the lower single-precision FP values of *a* and *b* are compared, and a 32-bit mask is returned; the upper three single-precision FP values are passed through from *a*. The mask is set to `0xffffffff` for each element where the comparison is true and `0x0` where the comparison is false.

The results of each intrinsic operation are placed in a register. This register is illustrated for each intrinsic with R or R0-R3. R0, R1, R2, and R3 each represent one of the four 32-bit pieces of the result register.

Compares for not-greater-than.

R0	R1	R2	R3
`!(a0 > b0) ? 0xffffffff : 0x0`	`!(a1 > b1) ? 0xffffffff : 0x0`	`!(a2 > b2) ? 0xffffffff : 0x0`	`!(a3 > b3) ? 0xffffffff : 0x0`

_mm_cmpnge_ss

```
__m128 _mm_cmpnge_ss(__m128 a, __m128 b);
```

Compares for not-greater-than-or-equal.

R0	R1	R2	R3
`!(a0 >= b0) ? 0xffffffff : 0x0`	a1	a2	a3

_mm_cmpnge_ps

```
__m128 _mm_cmpnge_ps(__m128 a, __m128 b);
```

Compares for not-greater-than-or-equal.

R0	R1	R2	R3
`!(a0 >= b0) ? 0xffffffff : 0x0`	`!(a1 >= b1) ? 0xffffffff : 0x0`	`!(a2 >= b2) ? 0xffffffff : 0x0`	`!(a3 >= b3) ? 0xffffffff : 0x0`

_mm_cmpord_ss

```
__m128 _mm_cmpord_ss(__m128 a, __m128 b);
```

Compares for ordered.

R0	R1	R2	R3
`(a0 ord? b0) ? 0xffffffff : 0x0`	a1	a2	a3

_mm_cmpord_ps

```
__m128 _mm_cmpord_ps(__m128 a, __m128 b);
```

Compares for ordered.

R0	R1	R2	R3
`(a0 ord? b0) ? 0xffffffff : 0x0`	`(a1 ord? b1) ? 0xffffffff : 0x0`	`(a2 ord? b2) ? 0xffffffff : 0x0`	`(a3 ord? b3) ? 0xffffffff : 0x0`

_mm_cmpunord_ss

```
__m128 _mm_cmpunord_ss(__m128 a, __m128 b);
```

Compares for unordered.

R0	R1	R2	R3
`(a0 unord? b0) ? 0xffffffff : 0x0`	a1	a2	a3

_mm_cmpunord_ps

```
__m128 _mm_cmpunord_ps(__m128 a, __m128 b);
```

Compares for unordered.

R0	R1	R2	R3
`(a0 unord? b0) ? 0xffffffff : 0x0`	`(a1 unord? b1) ? 0xffffffff : 0x0`	`(a2 unord? b2) ? 0xffffffff : 0x0`	`(a3 unord? b3) ? 0xffffffff : 0x0`

_mm_comieq_ss

```
int _mm_comieq_ss(__m128 a, __m128 b);
```

Compares the lower SP FP value of *a* and *b* for *a* equal to *b*. If *a* and *b* are equal, 1 is returned. Otherwise, 0 is returned.

R
`(a0 == b0) ? 0x1 : 0x0`

_mm_comilt_ss

```
int _mm_comilt_ss(__m128 a, __m128 b);
```

Compares the lower SP FP value of *a* and `b` for *a* less than *b*. If `a` is less than *b*, 1 is returned. Otherwise, 0 is returned.

R
`(a0 < b0) ? 0x1 : 0x0`

_mm_comile_ss

```
int _mm_comile_ss(__m128 a, __m128 b);
```

Compares the lower SP FP value of *a* and *b* for *a* less than or equal to *b*. If *a* is less than or equal to *b*, 1 is returned. Otherwise, 0 is returned.

R
`(a0 <= b0) ? 0x1 : 0x0`

_mm_comigt_ss

```
int _mm_comigt_ss(__m128 a, __m128 b);
```

Compares the lower SP FP value of *a* and *b* for *a* greater than *b*. If *a* is greater than *b* are equal, 1 is returned. Otherwise, 0 is returned.

R
`(a0 > b0) ? 0x1 : 0x0`

_mm_comige_ss

```
int _mm_comige_ss(__m128 a, __m128 b);
```

Compares the lower SP FP value of *a* and *b* for *a* greater than or equal to *b*. If *a* is greater than or equal to *b*, 1 is returned. Otherwise, 0 is returned.

R
`(a0 >= b0) ? 0x1 : 0x0`

_mm_comineq_ss

```
int _mm_comineq_ss(__m128 a, __m128 b);
```

Compares the lower SP FP value of *a* and *b* for *a* not equal to `b`. If *a* and *b* are not equal, 1 is returned. Otherwise, 0 is returned.

R
`(a0 != b0) ? 0x1 : 0x0`

_mm_ucomieq_ss

```
int _mm_ucomieq_ss(__m128 a, __m128 b);
```

Compares the lower SP FP value of *a* and *b* for *a* equal to `b`. If *a* and *b* are equal, 1 is returned. Otherwise, 0 is returned.

R
`(a0 == b0) ? 0x1 : 0x0`

_mm_ucomilt_ss

```
int _mm_ucomilt_ss(__m128 a, __m128 b);
```

Compares the lower SP FP value of *a* and *b* for *a* less than `b`. If *a* is less than *b*, 1 is returned. Otherwise, 0 is returned.

R
`(a0 < b0) ? 0x1 : 0x0`

_mm_ucomile_ss

```
int _mm_ucomile_ss(__m128 a, __m128 b);
```

Compares the lower SP FP value of *a* and *b* for *a* less than or equal to `b`. If *a* is less than or equal to *b*, 1 is returned. Otherwise, 0 is returned.

R
`(a0 <= b0) ? 0x1 : 0x0`

_mm_ucomigt_ss

```
int _mm_ucomigt_ss(__m128 a, __m128 b);
```

Compares the lower SP FP value of *a* and `b` for *a* greater than *b*. If *a* is greater than or equal to *b*, 1 is returned. Otherwise, 0 is returned.

R
`(a0 > b0) ? 0x1 : 0x0`

_mm_ucominge_ss

```
int _mm_ucomige_ss(__m128 a, __m128 b);
```

Compares the lower SP FP value of *a* and *b* for *a* greater than or equal to *b*. If *a* is greater than or equal to *b*, 1 is returned. Otherwise, 0 is returned.

R
`(a0 >= b0) ? 0x1 : 0x0`

_mm_ucomineq_ss

```
int _mm_ucomineq_ss(__m128 a, __m128 b);
```

Compares the lower SP FP value of *a* and *b* for *a* not equal to *b*. If *a* and *b* are not equal, 1 is returned. Otherwise, 0 is returned.

R
`r := (a0 != b0) ? 0x1 : 0x0`

Conversion Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for conversion operations are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in a register. This register is illustrated for each intrinsic with R or R0-R3. R0, R1, R2, and R3 each represent one of the four 32-bit pieces of the result register.

Intrinsics marked with * are available only on Intel® 64 architecture. The rest of the intrinsics can be implemented on both IA-32 and Intel® 64 architectures.

Intrinsic Name	Operation	Corresponding Intel® SSE Instruction
`_mm_cvtss_si32`	Convert to 32-bit integer	`CVTSS2SI`

Intrinsic Name	Operation	Corresponding Intel® SSE Instruction
`_mm_cvtss_si64*`	Convert to 64-bit integer	`CVTSS2SI`
`_mm_cvtps_pi32`	Convert to two 32-bit integers	`CVTPS2PI`
`_mm_cvttss_si32`	Convert to 32-bit integer	`CVTTSS2SI`
`_mm_cvttss_si64*`	Convert to 64-bit integer	`CVTTSS2SI`
`_mm_cvttps_pi32`	Convert to two 32-bit integers	`CVTTPS2PI`
`_mm_cvtsi32_ss`	Convert from 32-bit integer	`CVTSI2SS`
`_mm_cvtsi64_ss*`	Convert from 64-bit integer	`CVTSI2SS`
`_mm_cvtpi32_ps`	Convert from two 32-bit integers	`CVTTPI2PS`
`_mm_cvtpi16_ps`	Convert from four 16-bit integers	composite
`_mm_cvtpu16_ps`	Convert from four 16-bit integers	composite
`_mm_cvtpi8_ps`	Convert from four 8-bit integers	composite
`_mm_cvtpu8_ps`	Convert from four 8-bit integers	composite
`_mm_cvtpi32x2_ps`	Convert from four 32-bit integers	composite
`_mm_cvtps_pi16`	Convert to four 16-bit integers	composite
`_mm_cvtps_pi8`	Convert to four 8-bit integers	composite
`_mm_cvtss_f32`	Extract	composite

_mm_cvtss_si32

```
int _mm_cvtss_si32(__m128 a);
```

Converts the lower SP FP value of *a* to a 32-bit integer according to the current rounding mode.

R
`(int)a0`

_mm_cvtss_si64

```
__int64 _mm_cvtss_si64(__m128 a);
```

Converts the lower SP FP value of *a* to a 64-bit signed integer according to the current rounding mode.

NOTE
Use only on Intel© 64 architecture.

R
`(__int64)a0`

_mm_cvtps_pi32

```
__m64 _mm_cvtps_pi32(__m128 a);
```

Converts the two lower SP FP values of *a* to two 32-bit integers according to the current rounding mode, returning the integers in packed form.

R0	R1
`(int)a0`	`(int)a1`

_mm_cvttss_si32

```
int _mm_cvttss_si32(__m128 a);
```

Converts the lower SP FP value of *a* to a 32-bit integer with truncation.

R
`(int)a0`

_mm_cvttss_si64

```
__int64 _mm_cvttss_si64(__m128 a);
```

Converts the lower SP FP value of *a* to a 64-bit signed integer with truncation.

> **NOTE**
> Use only on Intel® 64 architecture.

R
`(__int64)a0`

_mm_cvttps_pi32

```
__m64 _mm_cvttps_pi32(__m128 a);
```

Converts the two lower SP FP values of *a* to two 32-bit integer with truncation, returning the integers in packed form.

R0	R1
`(int)a0`	`(int)a1`

_mm_cvtsi32_ss

```
__m128 _mm_cvtsi32_ss(__m128 a, int b);
```

Converts the 32-bit integer value *b* to an SP FP value; the upper three SP FP values are passed through from *a*.

R0	R1	R2	R3
`(float)b`	a1	a2	a3

_mm_cvtsi64_ss

`__m128 _mm_cvtsi64_ss(__m128 a, __int64 b);`

Converts the signed 64-bit integer value *b* to an SP FP value; the upper three SP FP values are passed through from *a*.

NOTE
Use only on Intel® 64 architecture.

R0	R1	R2	R3
`(float)b`	a1	a2	a3

_mm_cvtpi32_ps

`__m128 _mm_cvtpi32_ps(__m128 a, __m64 b);`

Converts the two 32-bit integer values in packed form in *b* to two SP FP values; the upper two SP FP values are passed through from *a*.

R0	R1	R2	R3
`(float)b0`	(float)b1	a2	a3

_mm_cvtpi16_ps

`__m128 _mm_cvtpi16_ps(__m64 a);`

Converts the four 16-bit signed integer values in *a* to four SP FP values.

R0	R1	R2	R3
`(float)a0`	(float)a1	`(float)a2`	`(float)a3`

_mm_cvtpu16_ps

`__m128 _mm_cvtpu16_ps(__m64 a);`

Converts the four 16-bit unsigned integer values in *a* to four SP FP values.

R0	R1	R2	R3
`(float)a0`	(float)a1	`(float)a2`	`(float)a3`

_mm_cvtpi8_ps

```
__m128 _mm_cvtpi8_ps(__m64 a);
```

Converts the lower four 8-bit signed integer values in *a* to four SP FP values.

R0	R1	R2	R3
(float)a0	(float)a1	(float)a2	(float)a3

_mm_cvtpu8_ps

```
__m128 _mm_cvtpu8_ps(__m64 a);
```

Converts the lower four 8-bit unsigned integer values in *a* to four SP FP values.

R0	R1	R2	R3
(float)a0	(float)a1	(float)a2	(float)a3

_mm_cvtpi32x2_ps

```
__m128 _mm_cvtpi32x2_ps(__m64 a, __m64 b);
```

Converts the two 32-bit signed integer values in *a* and the two 32-bit signed integer values in *b* to four SP FP values.

R0	R1	R2	R3
(float)a0	(float)a1	(float)b0	(float)b1

_mm_cvtps_pi16

```
__m64 _mm_cvtps_pi16(__m128 a);
```

Converts the four SP FP values in *a* to four signed 16-bit integer values.

R0	R1	R2	R3
(short)a0	(short)a1	(short)a2	(short)a3

_mm_cvtps_pi8

```
__m64 _mm_cvtps_pi8(__m128 a);
```

Converts the four SP FP values in *a* to the lower four signed 8-bit integer values of the result.

R0	R1	R2	R3
(char)a0	(char)a1	(char)a2	(char)a3

_mm_cvtss_f32

```
float _mm_cvtss_f32(__m128 a);
```

Extracts a SP floating-point value from the first vector element of an `__m128`. It does so in the most efficient manner possible in the context used.

Load Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for load operations are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in a register. This register is illustrated for each intrinsic with R0-R3. R0, R1, R2, and R3 each represent one of the four 32-bit pieces of the result register.

Intrinsic Name	Operation	Corresponding Intel® SSE Instruction
`_mm_loadh_pi`	Load high	`MOVHPS reg, mem`
`_mm_loadl_pi`	Load low	`MOVLPS reg, mem`
`_mm_load_ss`	Load the low value and clear the three high values	`MOVSS`
`_mm_load1_ps`	Load one value into all four words	`MOVSS + Shuffling`
`_mm_load_ps`	Load four values, address aligned	`MOVAPS`
`_mm_loadu_ps`	Load four values, address unaligned	`MOVUPS`
`_mm_loadr_ps`	Load four values in reverse	`MOVAPS + Shuffling`

_mm_loadh_pi

`__m128 _mm_loadh_pi(__m128 a, __m64 const *p);`

Sets the upper two SP FP values with 64 bits of data loaded from the address *p*; the lower two values are passed through from *a*.

R0	R1	R2	R3
a0	a1	*p0	*p1

_mm_loadl_pi

`__m128 _mm_loadl_pi(__m128 a, __m64 const *p);`

Sets the lower two SP FP values with 64 bits of data loaded from the address *p*; the upper two values are passed through from *a*.

R0	R1	R2	R3
a0	a1	*p0	*p1

R0	R1	R2	R3
*p0	*p1	a2	a3

_mm_load_ss

`__m128 _mm_load_ss(float * p);`

Loads a SP FP value into the low word and clears the upper three words.

R0	R1	R2	R3
*p	0.0	0.0	0.0

_mm_load1_ps

`__m128 _mm_load1_ps(float * p);`

Loads a SP FP value, copying it into all four words.

R0	R1	R2	R3
*p	*p	*p	*p

_mm_load_ps

`__m128 _mm_load_ps(float * p);`

Loads four SP FP values. The address must be 16-byte-aligned.

R0	R1	R2	R3
p[0]	p[1]	p[2]	p[3]

_mm_loadu_ps

`__m128 _mm_loadu_ps(float * p);`

Loads four SP FP values. The address need not be 16-byte-aligned.

R0	R1	R2	R3
p[0]	p[1]	p[2]	p[3]

_mm_loadr_ps

`__m128 _mm_loadr_ps(float * p);`

Loads four SP FP values in reverse order. The address must be 16-byte-aligned.

R0	R1	R2	R3
p[3]	p[2]	p[1]	p[0]

Set Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for set operations are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. R0, R1, R2, and R3 represent the registers in which results are placed.

Intrinsic Name	Operation	Corresponding Intel® SSE Instruction
`_mm_set_ss`	Set the low value and clear the three high values	Composite
`_mm_set1_ps`	Set all four words with the same value	Composite
`_mm_set_ps`	Set four values, address aligned	Composite
`_mm_setr_ps`	Set four values, in reverse order	Composite
`_mm_setzero_ps`	Clear all four values	Composite

_mm_set_ss

`__m128 _mm_set_ss(float w);`

Sets the low word of a SP FP value to *w* and clears the upper three words.

R0	R1	R2	R3
w	0.0	0.0	0.0

_mm_set1_ps

`__m128 _mm_set1_ps(float w);`

Sets the four SP FP values to *w*.

R0	R1	R2	R3
w	w	w	w

_mm_set_ps

`__m128 _mm_set_ps(float z, float y, float x, float w);`

Sets the four SP FP values to the inputs *w*, *x*, *y*, and *z*.

R0	R1	R2	R3
w	x	y	z

_mm_setr_ps

`__m128 _mm_setr_ps(float z, float y, float x, float w);`

Sets the four SP FP values to the inputs *w*, *x*, *y*, and *z* in reverse order.

R0	R1	R2	R3
z	y	x	w

_mm_setzero_ps

```
__m128 _mm_setzero_ps(void);
```

Clears the four SP FP values.

R0	R1	R2	R3
0.0	0.0	0.0	0.0

Store Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for store operations are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The description for each intrinsic contains a table detailing the returns. In these tables, p[*n*] is an access to the *n* element of the result.

Intrinsic Name	Operation	Corresponding Intel® SSE Instruction
`_mm_storeh_pi`	Store high	`MOVHPS mem, reg`
`_mm_storel_pi`	Store low	`MOVLPS mem, reg`
`_mm_store_ss`	Store the low value	`MOVSS`
`_mm_store1_ps`	Store the low value across all four words, address aligned	`Shuffling + MOVSS`
`_mm_store_ps`	Store four values, address aligned	`MOVAPS`
`_mm_storeu_ps`	Store four values, address unaligned	`MOVUPS`
`_mm_storer_ps`	Store four values, in reverse order	`MOVAPS + Shuffling`

_mm_storeh_pi

```
void _mm_storeh_pi(__m64 *p, __m128 a);
```

Stores the upper two SP FP values to the address *p*.

*p0	*p1
a2	a3

_mm_storel_pi

```
void _mm_storel_pi(__m64 *p, __m128 a);
```

Stores the lower two SP FP values of *a* to the address *p*.

*p0	*p1
a0	a1

_mm_store_ss

```
void _mm_store_ss(float * p, __m128 a);
```

Stores the lower SP FP value.

*p
a0

_mm_store1_ps

```
void _mm_store1_ps(float * p, __m128 a);
```

Stores the lower SP FP value across four words.

p[0]	p[1]	p[2]	p[3]
a0	a0	a0	a0

_mm_store_ps

```
void _mm_store_ps(float *p, __m128 a);
```

Stores four SP FP values. The address must be 16-byte-aligned.

p[0]	p[1]	p[2]	p[3]
a0	a1	a2	a3

_mm_storeu_ps

```
void _mm_storeu_ps(float *p, __m128 a);
```

Stores four SP FP values. The address need not be 16-byte-aligned.

p[0]	p[1]	p[2]	p[3]
a0	a1	a2	a3

_mm_storer_ps

```
void _mm_storer_ps(float * p, __m128 a);
```

Stores four SP FP values in reverse order. The address must be 16-byte-aligned.

p[0]	p[1]	p[2]	p[3]
a3	a2	a1	a0

Cacheability Support Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for cacheability support are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® SSE Instruction
`_mm_prefetch`	Load	`PREFETCH`
`_mm_stream_pi`	Store	`MOVNTQ`
`_mm_stream_ps`	Store	`MOVNTPS`
`_mm256_stream_ps`	Store	`VMOVNTPS`
`_mm_sfence`	Store fence	`SFENCE`

_mm_prefetch

`void _mm_prefetch(char const*a, int sel);`

Loads one cache line of data from address `a` to a location "closer" to the processor. The value `sel` specifies the type of prefetch operation: the constants `_MM_HINT_T0`, `_MM_HINT_T1`, `_MM_HINT_T2`, `_MM_HINT_NTA`, and `_MM_HINT_ET0` should be used for systems based on IA-32 architecture, and correspond to the type of `prefetch` instruction.

NOTE
The `_MM_HINT_ET0` hint lowers the intrinsic being to the instruction `PREFETCHW`, which is not included in Intel® SSE instructions. Check if the target CPU supports the `PREFETCHW` instruction before using `_MM_HINT_ET0`.

_mm_stream_pi

`void _mm_stream_pi(__m64 *p, __m64 a);`

Stores the data in *a* to the address *p* without polluting the caches. This intrinsic requires you to empty the multimedia state for the `MMX`™ register. See the topic The EMMS Instruction: Why You Need It.

_mm_stream_ps

`void _mm_stream_ps(float *p, __m128 a);`

Stores the data in *a* to the address *p* without polluting the caches. The address must be 16-byte-aligned.

_mm256_stream_ps

```
void _mm256_stream_ps(float *p, __m256 a);
```

Stores the data in *a* to the address *p* without polluting the caches. The address must be 32-byte (VEX.256 encoded version) aligned.

_mm_sfence

```
void _mm_sfence(void);
```

Guarantees that every preceding store is globally visible before any subsequent store.

The EMMS Instruction: Why You Need It

Integer Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for integer operations are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. R, R0, R1, ..., R7 represent the registers in which results are placed.

Before using these intrinsics, you must empty the multimedia state for the MMX™ technology register. See The EMMS Instruction: Why You Need It for more details.

Intrinsic Name	Operation	Corresponding Intel® SSE Instruction
`_mm_extract_pi16`	Extract one of four words	`PEXTRW`
`_mm_insert_pi16`	Insert word	`PINSRW`
`_mm_max_pi16`	Compute maximum	`PMAXSW`
`_mm_max_pu8`	Compute maximum, unsigned	`PMAXUB`
`_mm_min_pi16`	Compute minimum	`PMINSW`
`_mm_min_pu8`	Compute minimum, unsigned	`PMINUB`
`_mm_movemask_pi8`	Create eight-bit mask	`PMOVMSKB`
`_mm_mulhi_pu16`	Multiply, return high bits	`PMULHUW`
`_mm_shuffle_pi16`	Return a combination of four words	`PSHUFW`
`_mm_maskmove_si64`	Conditional Store	`MASKMOVQ`
`_mm_avg_pu8`	Compute rounded average	`PAVGB`
`_mm_avg_pu16`	Compute rounded average	`PAVGW`

Intrinsic Name	Operation	Corresponding Intel® SSE Instruction
`_mm_sad_pu8`	Compute sum of absolute differences	`PSADBW`

_mm_extract_pi16

```
int _mm_extract_pi16(__m64 a, int n);
```

Extracts one of the four words of *a*. The selector *n* must be an immediate.

R
`(n==0) ? a0 : ( (n==1) ? a1 : ( (n==2) ? a2 : a3 ) )`

_mm_insert_pi16

```
__m64 _mm_insert_pi16(__m64 a, int d, int n);
```

Inserts word `d` into one of four words of *a*. The selector *n* must be an immediate.

R0	R1	R2	R3
`(n==0) ? d : a0;`	`(n==1) ? d : a1;`	`(n==2) ? d : a2;`	`(n==3) ? d : a3;`

_mm_max_pi16

```
__m64 _mm_max_pi16(__m64 a, __m64 b);
```

Computes the element-wise maximum of the words in *a* and *b*.

R0	R1	R2	R3
`min(a0, b0)`	`min(a1, b1)`	`min(a2, b2)`	`min(a3, b3)`

_mm_max_pu8

```
__m64 _mm_max_pu8(__m64 a, __m64 b);
```

Computes the element-wise maximum of the unsigned bytes in *a* and *b*.

R0	R1	...	R7
`min(a0, b0)`	`min(a1, b1)`	`...`	`min(a7, b7)`

_mm_min_pi16

```
__m64 _mm_min_pi16(__m64 a, __m64 b);
```

Computes the element-wise minimum of the words in *a* and *b*.

R0	R1	R2	R3
`min(a0, b0)`	`min(a1, b1)`	`min(a2, b2)`	`min(a3, b3)`

_mm_min_pu8

```
__m64 _mm_min_pu8(__m64 a, __m64 b);
```

Computes the element-wise minimum of the unsigned bytes in *a* and *b*.

R0	R1	...	R7
`min(a0, b0)`	`min(a1, b1)`	`...`	`min(a7, b7)`

_mm_movemask_pi8

```
__m64 _mm_movemask_pi8(__m64 b);
```

Creates an 8-bit mask from the most significant bits of the bytes in *a*.

R
`sign(a7)<<7 | sign(a6)<<6 |... | sign(a0)`

_mm_mulhi_pu16

```
__m64 _mm_mulhi_pu16(__m64 a, __m64 b);
```

Multiplies the unsigned words in *a* and *b*, returning the upper 16 bits of the 32-bit intermediate results.

R0	R1	R2	R3
`hiword(a0 * b0)`	`hiword(a1 * b1)`	`hiword(a2 * b2)`	`hiword(a3 * b3)`

_mm_shuffle_pi16

```
__m64 _mm_shuffle_pi16(__m64 a, int n);
```

Returns a combination of the four words of *a*. The selector *n* must be an immediate.

R0	R1	R2	R3
`word (n&0x3) of a`	`word ((n>>2)&0x3) of a`	`word ((n>>4)&0x3) of a`	`word ((n>>6)&0x3) of a`

_mm_maskmove_si64

```
void _mm_maskmove_si64(__m64 d, __m64 n, char *p);
```

Conditionally stores byte elements of *d* to address *p*. The high bit of each byte in the selector *p* determines whether the corresponding byte in *d* will be stored.

`if (sign(n0))`	`if (sign(n1))`	...	`if (sign(n7))`
`p[0] := d0`	`p[1] := d1`	`...`	`p[7] := d7`

_mm_avg_pu8

```
__m64 _mm_avg_pu8(__m64 a, __m64 b);
```

Computes the (rounded) averages of the unsigned bytes in *a* and *b*.

R0	R1	...	R7
`(t >> 1) | (t & 0x01)`, where `t = (unsigned char)a0 + (unsigned char)b0`	`(t >> 1) | (t & 0x01)`, where `t = (unsigned char)a1 + (unsigned char)b1`	...	`((t >> 1) | (t & 0x01))`, where `t = (unsigned char)a7 + (unsigned char)b7`

_mm_avg_pu16

```
__m64 _mm_avg_pu16(__m64 a, __m64 b);
```

Computes the (rounded) averages of the unsigned short in *a* and *b*.

R0	R1	...	R7
`(t >> 1) | (t & 0x01)`, where `t = (unsigned int)a0 + (unsigned int)b0`	`(t >> 1) | (t & 0x01)`, where `t = (unsigned int)a1 + (unsigned int)b1`	...	`(t >> 1) | (t & 0x01)`, where `t = (unsigned int)a7 + (unsigned int)b7`

_mm_sad_pu8

```
__m64 _mm_sad_pu8(__m64 a, __m64 b);
```

Computes the sum of the absolute differences of the unsigned bytes in *a* and *b*, returning the value in the lower word. The upper three words are cleared.

R0	R1	R2	R3
`abs(a0-b0) +... + abs(a7-b7)`	0	0	0

Intrinsics to Read and Write Registers

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics to read from and write to registers are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® SSE Instruction
`_mm_getcsr`	Return control register	`STMXCSR`
`_mm_setcsr`	Set control register	`LDMXCSR`

_mm_getcsr

```
unsigned int _mm_getcsr(void);
```

Returns the contents of the control register.

_mm_setcsr

```
void _mm_setcsr(unsigned int i);
```

Sets the control register to the value specified by *i*.

Miscellaneous Intrinsics

The prototypes for Intel® Streaming SIMD Extensions (Intel® SSE) intrinsics for miscellaneous operations are in the `xmmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The results of each intrinsic operation are placed in registers. The information about what is placed in each register appears in the tables below, in the detailed explanation of each intrinsic. R, R0, R1, R2, and R3 represent the registers in which results are placed.

Intrinsic Name	Operation	Corresponding Intel® SSE Instruction
`_mm_shuffle_ps`	Shuffle	`SHUFPS`
`_mm_unpackhi_ps`	Unpack High	`UNPCKHPS`
`_mm_unpacklo_ps`	Unpack Low	`UNPCKLPS`
`_mm_move_ss`	Set low word, pass in three high values	`MOVSS`
`_mm_movehl_ps`	Move High to Low	`MOVHLPS`
`_mm_movelh_ps`	Move Low to High	`MOVLHPS`
`_mm_movemask_ps`	Create four-bit mask	`MOVMSKPS`
`_mm_undefined_ps`	Return vector of type __m128 with undefined elements.	This is a utility intrinsic that returns some arbitrary value.

_mm_shuffle_ps

```
__m128 _mm_shuffle_ps(__m128 a, __m128 b, unsigned int imm8);
```

Selects four specific SP FP values from *a* and *b*, based on the mask *imm8*. The mask must be an immediate. See Macro Function for Shuffle Using Intel® Streaming SIMD Extensions for a description of the shuffle semantics.

_mm_unpackhi_ps

```
__m128 _mm_unpackhi_ps(__m128 a, __m128 b);
```

Selects and interleaves the upper two SP FP values from *a* and *b*.

R0	R1	R2	R3
a2	b2	a3	b3

_mm_unpacklo_ps

```
__m128 _mm_unpacklo_ps(__m128 a, __m128 b);
```

Selects and interleaves the lower two SP FP values from *a* and *b*.

R0	R1	R2	R3
a0	b0	a1	b1

_mm_move_ss

```
__m128 _mm_move_ss( __m128 a, __m128 b);
```

Sets the low word to the SP FP value of *b*. The upper three SP FP values are passed through from *a*.

R0	R1	R2	R3
b0	a1	a2	a3

_mm_movehl_ps

```
__m128 _mm_movehl_ps(__m128 a, __m128 b);
```

Moves the upper two SP FP values of *b* to the lower two SP FP values of the result. The upper two SP FP values of *a* are passed through to the result.

R0	R1	R2	R3
b2	b3	a2	a3

_mm_movelh_ps

```
__m128 _mm_movelh_ps(__m128 a, __m128 b);
```

Moves the lower two SP FP values of *b* to the upper two SP FP values of the result. The lower two SP FP values of *a* are passed through to the result.

R0	R1	R2	R3
a0	a1	b0	b1

_mm_movemask_ps

```
int _mm_movemask_ps(__m128 a);
```

Creates a 4-bit mask from the most significant bits of the four SP FP values.

R
sign(a3)<<3 | sign(a2)<<2 | sign(a1)<<1 | sign(a0)

_mm_undefined_ps

```
extern __m128 _mm_undefined_ps(void);
```

Returns a vector of four single precision floating point elements. The content of the vector is not specified. The result is usually used as an argument to another intrinsic that requires all operands to be initialized, and when the content of a particular argument does not matter. This intrinsic is declared in the `immintrin.h` header file. It typically maps to a read of some XMM register and gets whatever value happens to live in that register at the time of the read.

For example, you can use such an intrinsic when you need to calculate a sum of packed double-precision floating-point values located in the *xmm* register.

Macro Function for Shuffle Using Intel® Streaming SIMD Extensions

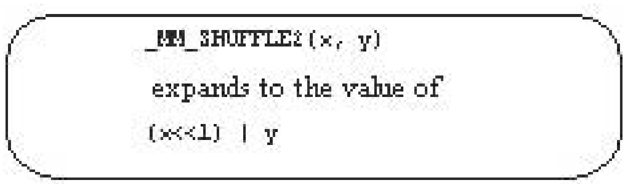
_mm256_undefined_ps() Returns a vector of eight single precision floating point elements. No corresponding Intel® AVX instruction.

Macro Functions

Macro Function for Shuffle Operations

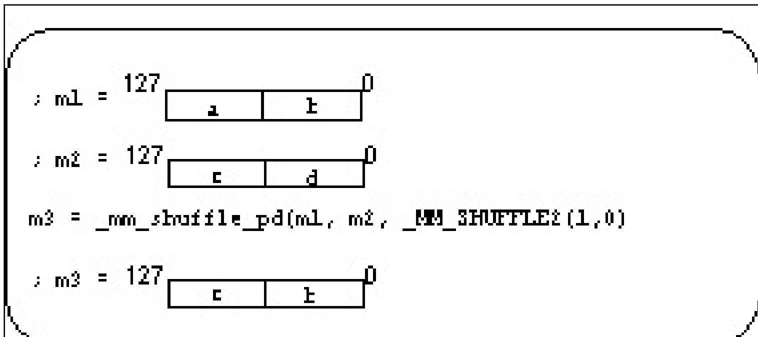
Intel® Streaming SIMD Extensions (Intel® SSE) provide a macro function to help create constants that describe shuffle operations. The macro takes four small integers (in the range of 0 to 3) and combines them into an 8-bit immediate value used by the `SHUFPS` instruction.

Shuffle Function Macro



You can view the four integers as selectors for choosing which two words from the first input operand and which two words from the second are to be put into the result word.

View of Original and Result Words with Shuffle Function Macro



Macro Functions to Read and Write Control Registers

The following macro functions enable you to read and write bits to and from the control register.

Exception State Macros	Macro Arguments
`_MM_SET_EXCEPTION_STATE(x)`	`_MM_EXCEPT_INVALID`
`_MM_GET_EXCEPTION_STATE()`	`_MM_EXCEPT_DIV_ZERO`
	`_MM_EXCEPT_DENORM`
Macro Definitions	`_MM_EXCEPT_OVERFLOW`
Write to and read from the six least significant control register bits, respectively.	
	`_MM_EXCEPT_UNDERFLOW`
	`_MM_EXCEPT_INEXACT`

The following example tests for a divide-by-zero exception.

Exception State Macros with _MM_EXCEPT_DIV_ZERO

```
if  (_MM_GET_EXCEPTION_STATE(x)  &  _MM_EXCEPT_DIV_ZERO)  {
    /* Exception has occurred */
}
```

Exception Mask Macros	Macro Arguments
`_MM_SET_EXCEPTION_MASK(x)`	`_MM_MASK_INVALID`
`_MM_GET_EXCEPTION_MASK ()`	`_MM_MASK_DIV_ZERO`
	`_MM_MASK_DENORM`
Macro Definitions	`_MM_MASK_OVERFLOW`
Write to and read from bit 7 – 12 control register bits, respectively.	
NOTE All six exception mask bits are always affected. Bits not set explicitly are cleared.	
	`_MM_MASK_UNDERFLOW`
	`_MM_MASK_INEXACT`

To mask the overflow and underflow exceptions and unmask all other exceptions, use the macros as follows:

```
_MM_SET_EXCEPTION_MASK(MM_MASK_OVERFLOW | _MM_MASK_UNDERFLOW)
```

The following table lists the macros to set and get rounding modes, and the macro arguments that can be passed with the macros.

Rounding Mode	Macro Arguments
`_MM_SET_ROUNDING_MODE(x)`	`_MM_ROUND_NEAREST`
`_MM_GET_ROUNDING_MODE()`	`_MM_ROUND_DOWN`
Macro Definition	`_MM_ROUND_UP`
Write to and read from bits 13 and 14 of the control register.	
	`_MM_ROUND_TOWARD_ZERO`

To test the rounding mode for round toward zero, use the `_MM_ROUND_TOWARD_ZERO` macro as follows.

```
if (_MM_GET_ROUNDING_MODE() == _MM_ROUND_TOWARD_ZERO) {
/* Rounding mode is round toward zero */
}
```

The following table lists the macros to set and get the flush-to-zero mode and the macro arguments that can be used.

Flush-to-Zero Mode	Macro Arguments
`_MM_SET_FLUSH_ZERO_MODE(x)`	`_MM_FLUSH_ZERO_ON`
`_MM_GET_FLUSH_ZERO_MODE()`	`_MM_FLUSH_ZERO_OFF`
Macro Definition	
Write to and read from bit 15 of the control register.	

To disable the flush-to-zero mode, use the `_MM_FLUSH_ZERO_OFF` macro.

```
_MM_SET_FLUSH_ZERO_MODE(_MM_FLUSH_ZERO_OFF)
```

Macro Function for Matrix Transposition

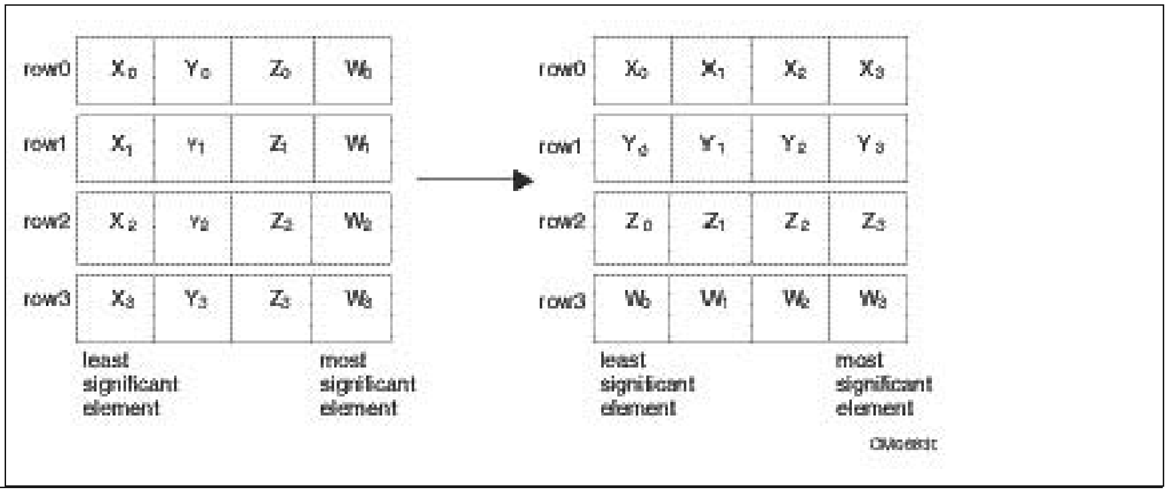
Intel® Streaming SIMD Extensions (Intel® SSE) provide the following macro function to transpose a 4 by 4 matrix of single precision floating point values.

`_MM_TRANSPOSE4_PS(row0, row1, row2, row3)`

The arguments `row0`, `row1`, `row2`, and `row3` are `__m128` values whose elements form the corresponding rows of a 4 by 4 matrix. The matrix transposition is returned in arguments `row0`, `row1`, `row2`, and `row3` where `row0` now holds column 0 of the original matrix, `row1` now holds column 1 of the original matrix, and so on.

The transposition function of this macro is illustrated in the figure below.

Matrix Transposition Using _MM_TRANSPOSE4_PS Macro



Intrinsics for MMX™ Technology

MMX™ technology is an extension to the Intel® architecture instruction set. The MMX™ instruction set adds 57 opcodes and a 64-bit quadword data type, and eight 64-bit registers. Each of the eight registers can be directly addressed using the register names `MM0` to `MM7`.

The prototypes for MMX™ technology intrinsics are in the `mmintrin.h` header file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Details about MMX™ Technology Intrinsics

The MMX™ technology instructions use the following features:

- Registers – Enable packed data of up to 128 bits in length for optimal single-instruction multiple data (SIMD) processing.
- Data Types – Enable packing of up to 16 elements of data in one register.

Registers

The MMX™ instructions use eight 64-bit registers (`mm0` to `mm7`) which are aliased on the floating-point stack registers.

Because each of these registers can hold more than one data element, the processor can process more than one data element simultaneously. This processing capability is also known as single-instruction multiple data (SIMD) processing.

For each computational and data manipulation instruction in the new extension sets, there is a corresponding C intrinsic that implements that instruction directly. This frees you from managing registers and assembly programming. Further, the compiler optimizes the instruction scheduling so that your executable runs faster.

Data Types

Intrinsic functions use four new C data types as operands, representing the new registers that are used as the operands to these intrinsic functions.

__m64 Data Type

The `__m64` data type is used to represent the contents of an MMX™ register, which is the register that is used by the MMX™ technology intrinsics. The `__m64` data type can hold eight 8-bit values, four 16-bit values, two 32-bit values, or one 64-bit value.

Data Types Usage Guidelines

These data types are not basic ANSI C data types. You must observe the following usage restrictions:

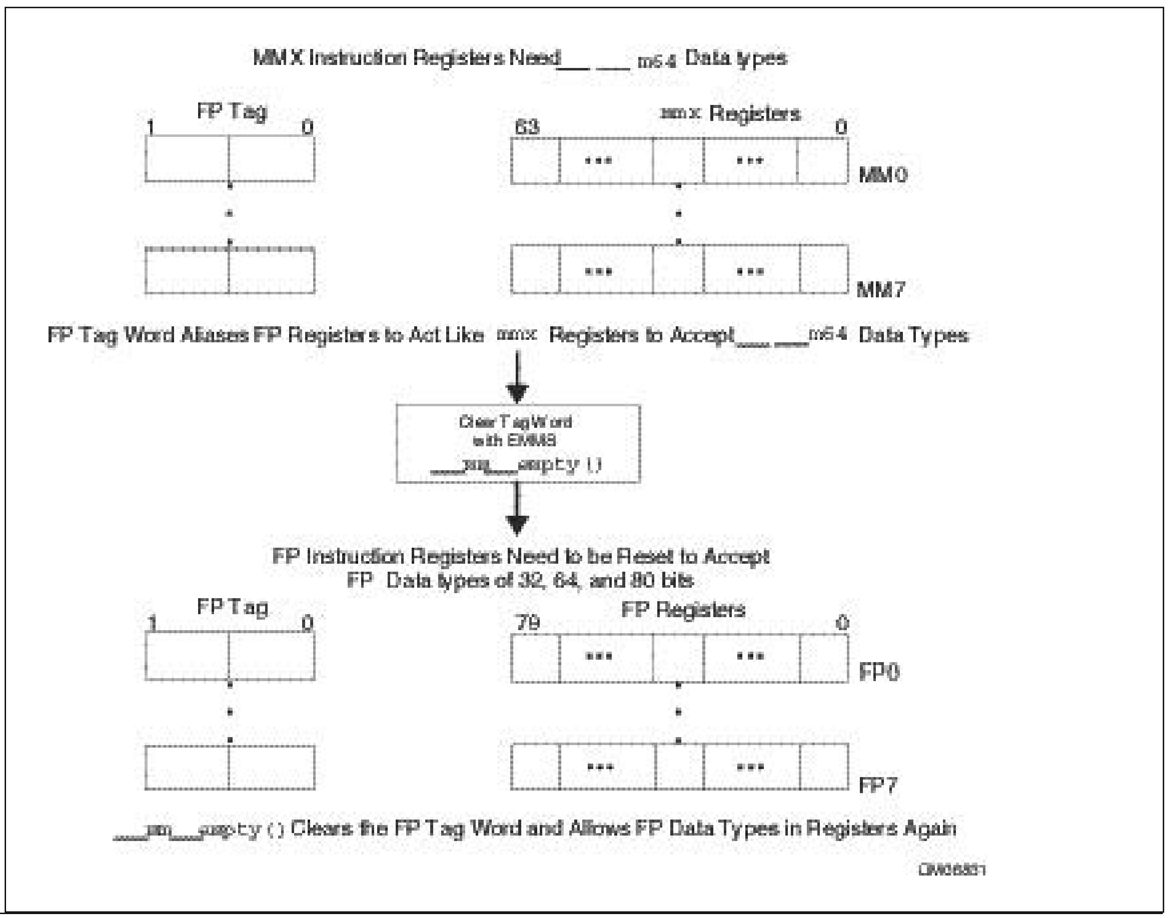
- Use data types only on either side of an assignment, as a return value, or as a parameter. You cannot use it with other arithmetic expressions (+, -, etc).
- Use data types as objects in aggregates, such as unions, to access the byte elements and structures.
- Use data types only with the respective intrinsics described in this documentation.

The EMMS Instruction: Why You Need It

Using EMMS is like emptying a container to accommodate new content. The EMMS instruction clears the MMX™ registers and sets the value of the floating-point tag word to empty.

You should clear the MMX™ registers before issuing a floating-point instruction because floating-point convention specifies that the floating-point stack be cleared after use. Insert the EMMS instruction at the end of all MMX™ code segments to avoid a floating-point overflow exception.

Why You Need EMMS to Reset After an MMX™ Instruction



Caution
Failure to empty the multimedia state after using an MMX™ technology instruction and before using a floating-point instruction can result in unexpected execution or poor performance.

EMMS Usage Guidelines

Here are guidelines for when to use the EMMS instruction:

- Use `_mm_empty()` after an MMX™ instruction if the next instruction is a floating-point (FP) instruction. For example, you should use the EMMS instruction before performing calculations on `float`, `double` or `long double`. You must be aware of all situations in which your code generates an MMX™ instruction:
  - when using an MMX™ technology intrinsic
  - when using Intel® Streaming SIMD Extensions (Intel® SSE) integer intrinsics that use the `__m64` data type
  - when referencing an `__m64` data type variable
  - when using an MMX™ instruction through inline assembly
- Use different functions for operations that use floating point instructions and those that use MMX™ instructions. This action eliminates the need to empty the multimedia state within the body of a critical loop.
- Use `_mm_empty()` during runtime initialization of `__m64` and FP data types. This ensures resetting the register between data type transitions.
- Do not use `_mm_empty()` before an MMX™ instruction, since using `_mm_empty()` before an MMX™ instruction incurs an operation with no benefit (no-op).
- See the Correct Usage and Incorrect Usage coding examples in the following table.

Incorrect Usage	Correct Usage
`__m64 x = _m_paddd(y, z);`	`__m64 x = _m_paddd(y, z);`
`float f = init();`	`float f = ( _mm_empty(), init());`

General Support Intrinsics (MMX™ technology)

This topic summarizes the MMX™ technology general support intrinsics.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding MMX™ Instruction
`_mm_empty`	Empty `MM` state	`EMMS`
`_mm_cvtsi32_si64`	Convert from `int`	`MOVD`
`_mm_cvtsi64_si32`	Convert to `int`	`MOVD`
`_mm_cvtsi64_m64`	Convert from `__int64`	`MOVQ`
`_mm_cvtm64_si64`	Convert to `__int64`	`MOVQ`
`_mm_packs_pi16`	Pack	`PACKSSWB`

Intrinsic Name	Operation	Corresponding MMX™ Instruction
`_mm_packs_pi32`	Pack	`PACKSSDW`
`_mm_packs_pu16`	Pack	`PACKUSWB`
`_mm_unpackhi_pi8`	Interleave	`PUNPCKHBW`
`_mm_unpackhi_pi16`	Interleave	`PUNPCKHWD`
`_mm_unpackhi_pi32`	Interleave	`PUNPCKHDQ`
`_mm_unpacklo_pi8`	Interleave	`PUNPCKLBW`
`_mm_unpacklo_pi16`	Interleave	`PUNPCKLWD`
`_mm_unpacklo_pi32`	Interleave	`PUNPCKLDQ`

_mm_empty

```
void _mm_empty(void);
```

Empties the multimedia state.

_mm_cvtsi32_si64

```
__m64 _mm_cvtsi32_si64(int i);
```

Converts the integer object *i* to a 64-bit `__m64` object. The integer value is zero-extended to 64 bits.

_mm_cvtsi64_si32

```
int _mm_cvtsi64_si32(__m64 m);
```

Converts the lower 32 bits of the `__m64` object *m* to an integer.

_mm_cvtsi64_m64

```
__m64 _mm_cvtsi64_m64(__int64 i);
```

Moves the 64-bit integer object *i* to a `__m64` object

_mm_cvtm64_si64

```
__m64 _mm_cvtm64_si64(__m64 m);
```

Moves the `__m64` object *m* to a 64-bit integer

_mm_packs_pi16

```
__m64 _mm_packs_pi16(__m64 m1, __m64 m2);
```

Packs the four 16-bit values from *m1* into the lower four 8-bit values of the result with signed saturation, and pack the four 16-bit values from *m2* into the upper four 8-bit values of the result with signed saturation.

_mm_packs_pi32

```
__m64 _mm_packs_pi32(__m64 m1, __m64 m2);
```

Packs the two 32-bit values from *m1* into the lower two 16-bit values of the result with signed saturation, and pack the two 32-bit values from *m2* into the upper two 16-bit values of the result with signed saturation.

_mm_packs_pu16

```
__m64 _mm_packs_pu16(__m64 m1, __m64 m2);
```

Packs the four 16-bit values from *m1* into the lower four 8-bit values of the result with unsigned saturation, and pack the four 16-bit values from *m2* into the upper four 8-bit values of the result with unsigned saturation.

_mm_unpackhi_pi8

```
__m64 _mm_unpackhi_pi8(__m64 m1, __m64 m2);
```

Interleaves the four 8-bit values from the high half of *m1* with the four values from the high half of *m2*. The interleaving begins with the data from *m1*.

_mm_unpackhi_pi16

```
__m64 _mm_unpackhi_pi16(__m64 m1, __m64 m2);
```

Interleaves the two 16-bit values from the high half of *m1* with the two values from the high half of *m2*. The interleaving begins with the data from *m1*.

_mm_unpackhi_pi32

```
__m64 _mm_unpackhi_pi32(__m64 m1, __m64 m2);
```

Interleaves the 32-bit value from the high half of *m1* with the 32-bit value from the high half of *m2*. The interleaving begins with the data from *m1*.

_mm_unpacklo_pi8

```
__m64 _mm_unpacklo_pi8(__m64 m1, __m64 m2);
```

Interleaves the four 8-bit values from the low half of *m1* with the four values from the low half of *m2*. The interleaving begins with the data from *m1*.

_mm_unpacklo_pi16

```
__m64 _mm_unpacklo_pi16(__m64 m1, __m64 m2);
```

Interleaves the two 16-bit values from the low half of *m1* with the two values from the low half of *m2*. The interleaving begins with the data from *m1*.

_mm_unpacklo_pi32

```
__m64 _mm_unpacklo_pi32(__m64 m1, __m64 m2);
```

Interleaves the 32-bit value from the low half of *m1* with the 32-bit value from the low half of *m2*. The interleaving begins with the data from *m1*.

Packed Arithmetic Intrinsics (MMX™ technology)

This topic summarizes the MMX™ technology packed arithmetic intrinsics.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding MMX™ Instruction
`_mm_add_pi8`	Addition	`PADDB`
`_mm_add_pi16`	Addition	`PADDW`
`_mm_add_pi32`	Addition	`PADDD`
`_mm_adds_pi8`	Addition	`PADDSB`
`_mm_adds_pi16`	Addition	`PADDSW`
`_mm_adds_pu8`	Addition	`PADDUSB`
`_mm_adds_pu16`	Addition	`PADDUSW`
`_mm_sub_pi8`	Subtraction	`PSUBB`
`_mm_sub_pi16`	Subtraction	`PSUBW`
`_mm_sub_pi32`	Subtraction	`PSUBD`
`_mm_subs_pi8`	Subtraction	`PSUBSB`
`_mm_subs_pi16`	Subtraction	`PSUBSW`
`_mm_subs_pu8`	Subtraction	`PSUBUSB`
`_mm_subs_pu16`	Subtraction	`PSUBUSW`
`_mm_madd_pi16`	Multiply and add	`PMADDWD`
`_mm_mulhi_pi16`	Multiplication	`PMULHW`
`_mm_mullo_pi16`	Multiplication	`PMULLW`

_mm_add_pi8

```
__m64 _mm_add_pi8(__m64 m1, __m64 m2);
```

Add the eight 8-bit values in *m1* to the eight 8-bit values in *m2*.

_mm_add_pi16

```
__m64 _mm_add_pi16(__m64 m1, __m64 m2);
```

Add the four 16-bit values in *m1* to the four 16-bit values in *m2*.

_mm_add_pi32

```
__m64 _mm_add_pi32(__m64 m1, __m64 m2);
```

Add the two 32-bit values in *m1* to the two 32-bit values in *m2*.

_mm_adds_pi8

```
__m64 _mm_adds_pi8(__m64 m1, __m64 m2);
```

Add the eight signed 8-bit values in *m1* to the eight signed 8-bit values in *m2* using saturating arithmetic.

_mm_adds_pi16

```
__m64 _mm_adds_pi16(__m64 m1, __m64 m2);
```

Add the four signed 16-bit values in *m1* to the four signed 16-bit values in *m2* using saturating arithmetic.

_mm_adds_pu8

```
__m64 _mm_adds_pu8(__m64 m1, __m64 m2);
```

Add the eight unsigned 8-bit values in *m1* to the eight unsigned 8-bit values in *m2* and using saturating arithmetic.

_mm_adds_pu16

```
__m64 _mm_adds_pu16(__m64 m1, __m64 m2);
```

Add the four unsigned 16-bit values in *m1* to the four unsigned 16-bit values in *m2* using saturating arithmetic.

_mm_sub_pi8

```
__m64 _mm_sub_pi8(__m64 m1, __m64 m2);
```

Subtract the eight 8-bit values in *m2* from the eight 8-bit values in *m1*.

_mm_sub_pi16

```
__m64 _mm_sub_pi16(__m64 m1, __m64 m2);
```

Subtract the four 16-bit values in *m2* from the four 16-bit values in *m1*.

_mm_sub_pi32

```
__m64 _mm_sub_pi32(__m64 m1, __m64 m2);
```

Subtract the two 32-bit values in *m2* from the two 32-bit values in `m1`.

_mm_subs_pi8

```
__m64 _mm_subs_pi8(__m64 m1, __m64 m2);
```

Subtract the eight signed 8-bit values in *m2* from the eight signed 8-bit values in *m1* using saturating arithmetic.

_mm_subs_pi16

```
__m64 _mm_subs_pi16(__m64 m1, __m64 m2);
```

Subtract the four signed 16-bit values in *m2* from the four signed 16-bit values in *m1* using saturating arithmetic.

_mm_subs_pu8

```
__m64 _mm_subs_pu8(__m64 m1, __m64 m2);
```

Subtract the eight unsigned 8-bit values in *m2* from the eight unsigned 8-bit values in *m1* using saturating arithmetic.

_mm_subs_pu16

```
__m64 _mm_subs_pu16(__m64 m1, __m64 m2);
```

Subtract the four unsigned 16-bit values in *m2* from the four unsigned 16-bit values in *m1* using saturating arithmetic.

_mm_madd_pi16

```
__m64 _mm_madd_pi16(__m64 m1, __m64 m2);
```

Multiply four 16-bit values in *m1* by four 16-bit values in *m2* producing four 32-bit intermediate results, which are then summed by pairs to produce two 32-bit results.

_mm_mulhi_pi16

```
__m64 _mm_mulhi_pi16(__m64 m1, __m64 m2);
```

Multiply four signed 16-bit values in *m1* by four signed 16-bit values in *m2* and produce the high 16 bits of the four results.

_mm_mullo_pi16

```
__m64 _mm_mullo_pi16(__m64 m1, __m64 m2);
```

Multiply four 16-bit values in *m1* by four 16-bit values in *m2* and produce the low 16 bits of the four results.

Shift Intrinsics (MMX™ technology)

This topic summarizes the MMX™ technology shift intrinsics.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding MMX™ Instruction
`_mm_sll_pi16`	Logical shift left	`PSLLW`
`_mm_slli_pi16`	Logical shift left	`PSLLWI`
`_mm_sll_pi32`	Logical shift left	`PSLLD`
`_mm_slli_pi32`	Logical shift left	`PSLLDI`
`_mm_sll_pi64`	Logical shift left	`PSLLQ`
`_mm_slli_pi64`	Logical shift left	`PSLLQI`
`_mm_sra_pi16`	Arithmetic shift right	`PSRAW`
`_mm_srai_pi16`	Arithmetic shift right	`PSRAWI`

Intrinsic Name	Operation	Corresponding MMX™ Instruction
`_mm_sra_pi32`	Arithmetic shift right	`PSRAD`
`_mm_srai_pi32`	Arithmetic shift right	`PSRADI`
`_mm_srl_pi16`	Logical shift right	`PSRLW`
`_mm_srli_pi16`	Logical shift right	`PSRLWI`
`_mm_srl_pi32`	Logical shift right	`PSRLD`
`_mm_srli_pi32`	Logical shift right	`PSRLDI`
`_mm_srl_pi64`	Logical shift right	`PSRLQ`
`_mm_srli_pi64`	Logical shift right	`PSRLQI`

_mm_sll_pi16

```
__m64 _mm_sll_pi16(__m64 m, __m64 count);
```

Shifts four 16-bit values in *m* left the amount specified by *count* while shifting in zeros.

_mm_slli_pi16

```
__m64 _mm_slli_pi16(__m64 m, int count);
```

Shifts four 16-bit values in *m* left the amount specified by *count* while shifting in zeros. For the best performance, *count* should be a constant.

_mm_sll_pi32

```
__m64 _mm_sll_pi32(__m64 m, __m64 count);
```

Shifts two 32-bit values in *m* left the amount specified by *count* while shifting in zeros.

_mm_slli_pi32

```
__m64 _mm_slli_pi32(__m64 m, int count);
```

Shifts two 32-bit values in *m* left the amount specified by *count* while shifting in zeros. For the best performance, *count* should be a constant.

_mm_sll_pi64

```
__m64 _mm_sll_pi64(__m64 m, __m64 count);
```

Shifts the 64-bit value in *m* left the amount specified by *count* while shifting in zeros.

_mm_slli_pi64

```
__m64 _mm_slli_pi64(__m64 m, int count);
```

Shifts the 64-bit value in *m* left the amount specified by *count* while shifting in zeros. For the best performance, *count* should be a constant.

_mm_sra_pi16

```
__m64 _mm_sra_pi16(__m64 m, __m64 count);
```

Shifts four 16-bit values in *m* right the amount specified by *count* while shifting in the sign bit.

_mm_srai_pi16

```
__m64 _mm_srai_pi16(__m64 m, int count);
```

Shifts four 16-bit values in *m* right the amount specified by *count* while shifting in the sign bit. For the best performance, *count* should be a constant.

_mm_sra_pi32

```
__m64 _mm_sra_pi32(__m64 m, __m64 count);
```

Shifts two 32-bit values in *m* right the amount specified by *count* while shifting in the sign bit.

_mm_srai_pi32

```
__m64 _mm_srai_pi32(__m64 m, int count);
```

Shifts two 32-bit values in *m* right the amount specified by *count* while shifting in the sign bit. For the best performance, *count* should be a constant.

_mm_srl_pi16

```
__m64 _mm_srl_pi16(__m64 m, __m64 count);
```

Shifts four 16-bit values in *m* right the amount specified by *count* while shifting in zeros.

_mm_srli_pi16

```
__m64 _mm_srli_pi16(__m64 m, int count);
```

Shifts four 16-bit values in *m* right the amount specified by *count* while shifting in zeros. For the best performance, *count* should be a constant.

_mm_srl_pi32

```
__m64 _mm_srl_pi32(__m64 m, __m64 count);
```

Shifts two 32-bit values in *m* right the amount specified by *count* while shifting in zeros.

_mm_srli_pi32

```
__m64 _mm_srli_pi32(__m64 m, int count);
```

Shifts two 32-bit values in *m* right the amount specified by *count* while shifting in zeros. For the best performance, *count* should be a constant.

_mm_srl_pi64

```
__m64 _mm_srl_pi64(__m64 m, __m64 count);
```

Shifts the 64-bit value in *m* right the amount specified by *count* while shifting in zeros.

_mm_srli_pi64

```
__m64 _mm_srli_pi64(__m64 m, int count);
```

Shifts the 64-bit value in *m* right the amount specified by *count* while shifting in zeros. For the best performance, *count* should be a constant.

Logical Intrinsics (MMX™ technology)

This topic summarizes the MMX™ technology logical intrinsics.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding MMX™ Instruction
`_mm_and_si64`	Bitwise AND	`PAND`
`_mm_andnot_si64`	Bitwise ANDNOT	`PANDN`
`_mm_or_si64`	Bitwise OR	`POR`
`_mm_xor_si64`	Bitwise Exclusive OR	`PXOR`

_mm_and_si64

```
__m64 _mm_and_si64(__m64 m1, __m64 m2);
```

Perform a bitwise AND of the 64-bit value in *m1* with the 64-bit value in *m2*.

_mm_andnot_si64

```
__m64 _mm_andnot_si64(__m64 m1, __m64 m2);
```

Perform a bitwise NOT on the 64-bit value in *m1* and use the result in a bitwise AND with the 64-bit value in *m2*.

_mm_or_si64

```
__m64 _mm_or_si64(__m64 m1, __m64 m2);
```

Perform a bitwise OR of the 64-bit value in *m1* with the 64-bit value in *m2*.

_mm_xor_si64

```
__m64 _mm_xor_si64(__m64 m1, __m64 m2);
```

Perform a bitwise XOR of the 64-bit value in *m1* with the 64-bit value in *m2*.

Compare Intrinsics (MMX™ technology)

This topic summarizes the MMX™ technology compare intrinsics.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding MMX™ Instruction
`_mm_cmpeq_pi8`	Equal	`PCMPEQB`
`_mm_cmpeq_pi16`	Equal	`PCMPEQW`
`_mm_cmpeq_pi32`	Equal	`PCMPEQD`
`_mm_cmpgt_pi8`	Greater Than	`PCMPGTB`
`_mm_cmpgt_pi16`	Greater Than	`PCMPGTW`
`_mm_cmpgt_pi32`	Greater Than	`PCMPGTD`

_mm_ cmpeq_pi8

```
__m64 _mm_ cmpeq_pi8(__m64 m1, __m64 m2);
```

Sets the corresponding 8-bit resulting values to all ones if the 8-bit values in *m1* are equal to the corresponding 8-bit values in *m2*; otherwise sets them to all zeros.

_mm_ cmpeq_pi16

```
__m64 _mm_ cmpeq_pi16(__m64 m1, __m64 m2);
```

Sets the corresponding 16-bit resulting values to all ones if the 16-bit values in *m1* are equal to the corresponding 16-bit values in *m2*; otherwise set them to all zeros.

_mm_ cmpeq_pi32

```
__m64 _mm_ cmpeq_pi32(__m64 m1, __m64 m2);
```

Sets the corresponding 32-bit resulting values to all ones if the 32-bit values in *m1* are equal to the corresponding 32-bit values in *m2*; otherwise set them to all zeros.

_mm_ cmpgt_pi8

```
__m64 _mm_ cmpgt_pi8(__m64 m1, __m64 m2);
```

Sets the corresponding 8-bit resulting values to all ones if the 8-bit signed values in *m1* are greater than the corresponding 8-bit signed values in *m2*; otherwise set them to all zeros.

_mm_ cmpgt_pi16

```
__m64 _mm_ cmpgt_pi16(__m64 m1, __m64 m2);
```

Sets the corresponding 16-bit resulting values to all ones if the 16-bit signed values in *m1* are greater than the corresponding 16-bit signed values in *m2*; otherwise set them to all zeros.

_mm_ cmpgt_pi32

```
__m64 _mm_ cmpgt_pi32(__m64 m1, __m64 m2);
```

Sets the corresponding 32-bit resulting values to all ones, if the 32-bit signed values in *m1* are greater than the corresponding 32-bit signed values in *m2*; otherwise set them all to zeros.

Set Intrinsics (MMX™ technology)

This topic summarizes the MMX™ technology intrinsics.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

NOTE
In the descriptions regarding the bits of the `MMX`™ register, bit 0 is the least significant and bit 63 is the most significant.

Intrinsic Name	Operation	Corresponding MMX™ Instruction
`_mm_setzero_si64`	set to zero	`PXOR`
`_mm_set_pi32`	set integer values	Composite
`_mm_set_pi16`	set integer values	Composite
`_mm_set_pi8`	set integer values	Composite
`_mm_set1_pi32`	set integer values	Composite
`_mm_set1_pi16`	set integer values	Composite
`_mm_set1_pi8`	set integer values	Composite
`_mm_setr_pi32`	set integer values	Composite
`_mm_setr_pi16`	set integer values	Composite
`_mm_setr_pi8`	set integer values	Composite

_mm_setzero_si64

```
__m64 _mm_setzero_si64(void);
```

Sets the 64-bit value to zero.

R
`0x0`

_mm_set_pi32

```
__m64 _mm_set_pi32(int i1, int i0);
```

Sets the two signed 32-bit integer values.

R0	R1
`i0`	`i1`

_mm_set_pi16

```
__m64 _mm_set_pi16(short s3, short s2, short s1, short s0);
```

Sets the four signed 16-bit integer values.

R0	R1	R2	R3
w0	w1	w2	w3

_mm_set_pi8

```
__m64 _mm_set_pi8(char b7, char b6, char b5, char b4, char b3, char b2, char b1, char
b0);
```

Sets the eight signed 8-bit integer values.

R0	R1	...	R7
b0	b1	...	b7

_mm_set1_pi32

```
__m64 _mm_set1_pi32(int i);
```

Sets the two signed 32-bit integer values to *i*.

R0	R1
i	i

_mm_set1_pi16

```
__m64 _mm_set1_pi16(short s);
```

Sets the four signed 16-bit integer values to *s*.

R0	R1	R2	R3
w	w	w	w

_mm_set1_pi8

```
__m64 _mm_set1_pi8(char b);
```

Sets the eight signed 8-bit integer values to *b*.

R0	R1	...	R7
b	b	...	b

_mm_setr_pi32

```
__m64 _mm_setr_pi32(int i1, int i0);
```

Sets the two signed 32-bit integer values in reverse order.

R0	R1
i1	i0

_mm_setr_pi16

```
__m64 _mm_setr_pi16(short s3, short s2, short s1, short s0);
```

Sets the four signed 16-bit integer values in reverse order.

R0	R1	R2	R3
w3	w2	w1	w0

_mm_setr_pi8

```
__m64 _mm_setr_pi8(char b7, char b6, char b5, char b4, char b3, char b2, char b1, char
b0);
```

Sets the eight signed 8-bit integer values in reverse order.

R0	R1	...	R7
b7	b6	...	b0

Intrinsics for Advanced Encryption Standard Implementation

The Intel® C++ Compiler Classic provides intrinsics to enable carry-less multiplication and encryption based on Advanced Encryption Standard (AES) specifications. The carry-less multiplication intrinsic corresponds to a single new instruction, `PCLMULQDQ`. The AES extension intrinsics correspond to AES extension intructions.

The AES extension instructions and the `PCLMULQDQ` instruction follow the same system software requirements for `XMM` state support and single-instruction multiple data (SIMD) floating-point exception support as Intel® Streaming SIMD Extensions 2 (Intel® SSE2), Intel® Streaming SIMD Extensions 3 (Intel® SSE3), Intel Supplemental Streaming SIMD Extensions 3 (SSSE3), and Intel® Streaming SIMD Extensions 4 (Intel® SSE4) extensions.

Intel®64 processors using 32nm processing technology support the AES extension instructions as well as the `PCLMULQDQ` instruction.

AES Encryption and Cryptographic Processing

AES encryption involves processing 128-bit input data (plaintext) through a finite number of iterative operation, referred to as AES round, into a 128-bit encrypted block (ciphertext). Decryption follows the reverse direction of iterative operation using the equivalent inverse cipher instead of the inverse cipher.

The cryptographic processing at each round involves two input data, one is the state, the other is the round key. Each round uses a different round key. The round keys are derived from the cipher key using a key schedule algorithm. The key schedule algorithm is independent of the data processing of encryption/ decryption, and can be carried out independently from the encryption/decryption phase.

The AES standard supports cipher key of sizes 128, 192, and 256 bits. The respective cipher key sizes corresponds to 10, 12, and 14 rounds of iteration.

Carry-less Multiplication Instruction and AES Extension Instructions

A single instruction, PCLMULQDQ, performs carry-less multiplication for two binary numbers that are up to 64-bit wide.

The AES extensions provide:

- two instructions to accelerate AES rounds on encryption (AESENC and AESENCLAST)
- two instructions for AES rounds on decryption using the equivalent inverse cipher (AESDEC and AESENCLAST)
- instructions for the generation of key schedules (AESIMC and AESENCLAST)

Detecting Support for Using Instructions

Before any application attempts to use the PCLMULQDQ or the AES extension instructions, it must first detect if the instructions are supported by the processor.

To detect support for the PCLMULQDQ instruction, your application must check the following:

```
CPUID.01H:ECX.PCLMULQDQ[bit 1] = 1.
```

To detect support for the AES extension instructions, your application must check the following:

```
CPUID.01H:ECX.AES[bit 25] = 1.
```

Operating systems that support handling of the SSE state also support applications that use AES extension instruction and the PCLMULQDQ instruction.

Intrinsics for Carry-less Multiplication Instruction and Advanced Encryption Standard Instructions

The prototypes for the Carry-less multiplication intrinsic and the Advanced Encryption Standard (AES) intrinsics are defined in the wmmintrin.h file.

To use these intrinsics, include the immintrin.h file as follows:

```
#include <immintrin.h>
```

Carry-less Multiplication Intrinsic

The single general purpose block encryption intrinsic description is provided below.

`__m128i _mm_clmulepi64_si128(__m128i v1, __m128i v2, const int imm8);`

Performs a carry-less multiplication of one quadword of v1 by one quadword of v2, and returns the result. The imm8 value is used to determine which quadwords of v1 and v2 should be used.

Corresponding Instruction: PCLMULQDQ

Advanced Encryption Standard Intrinsics

The AES intrinsics are described below.

`__m128i _mm_aesdec_si128(__m128i v, __m128i rkey);`

Performs one round of an AES decryption flow using the Equivalent Inverse Cipher operating on a 128-bit data (state) from v with a 128-bit round key from rkey.

Corresponding Instruction: AESDEC

`__m128i _mm_aesdeclast_si128(__m128i v, __m128i rkey);`

Performs the last round of an AES decryption flow using the Equivalent Inverse Cipher operating on a 128-bit data (state) from `v` with a 128-bit round key from `rkey`.

Corresponding Instruction: `AESDECLAST`

```
__m128i _mm_aesenc_si128(__m128i v, __m128i rkey);
```

Performs one round of an AES encryption flow operating on a 128-bit data (state) from `v` with a 128-bit round key from `rkey`.

Corresponding Instruction:`AESENC`

```
__m128i _mm_aesenclast_si128(__m128i v, __m128i rkey);
```

Performs the last round of an AES encryption flow operating on a 128-bit data (state) from `v` with a 128-bit round key from `rkey`.

Corresponding Instruction: `AESENCLAST`

```
__m128i _mm_aesimc_si128(__m128i v);
```

Performs the InvMixColumn transformation on a 128-bit round key from`v` and returns the result.

Corresponding Instruction: `AESIMC`

```
__m128i _mm_aeskeygenassist_si128(__m128i ckey, const int rcon);
```

Assists in AES round key generation using an 8-bit Round Constant (RCON) specified in `rcon` operating on 128 bits of data specified in `ckey` and returns the result.

Corresponding Instruction: `AESKEYGENASSIST`

Intrinsics for Converting Half Floats

The half-float or 16-bit float is a popular type in some application domains. The half-float type is regarded as a storage type because although data is often stored as a half-float, computation is never done on values in these type. Usually values are converted to regular 32-bit floats before any computation.

Support for half-float type is restricted to just conversions to/from 32-bit floats. The main benefits of using half float type are:

- reduced storage requirements
- less consumption of memory bandwidth and cache
- accuracy and precision adequate for many applications

Half Float Intrinsics

The half-float intrinsics are provided to convert half-float values to 32-bit floats for computation purposes and, conversely, 32-bit float values to half-float values for data storage purposes.

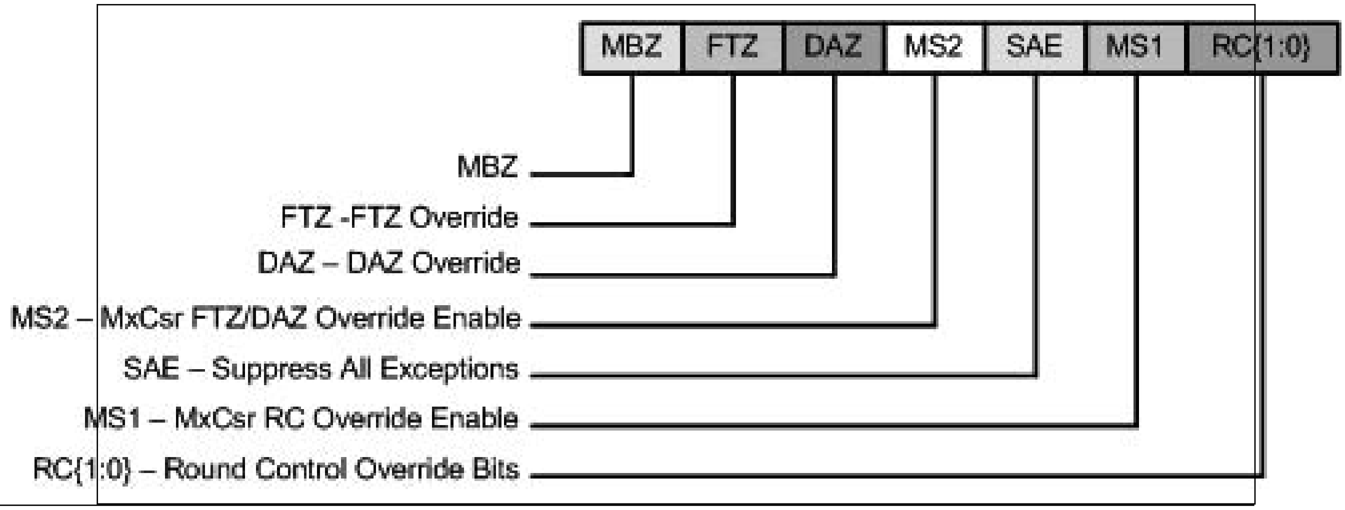
The intrinsics are translated into library calls that do the actual conversions.

The half-float intrinsics are available on IA-32 and Intel® 64 architectures running supported operating systems. The minimum processor requirement is an Intel® Pentium 4 processor and an operating system supporting Intel® Streaming SIMD Extensions 2 (Intel® SSE2) instructions.

Role of Immediate Byte in Half Float Intrinsic Operations

For all half-float intrinsics an immediate byte controls rounding mode, flush to zero, and other non-volatile set values. The format of the `imm8` byte is as shown in the diagram below.

The `imm8` value is used for special `MXCSR` overrides.



In the diagram,

- MBZ = Most significant Bit is Zero; used for error checking
- MS1 = 1 : use MXCSR RC, else use imm8.RC
- SAE = 1 : all exceptions are suppressed
- MS2 = 1 : use MXCSR FTZ/DAZ control, else use imm8.FTZ/DAZ.

The compiler passes the bits to the library function, with error checking - the most significant bit must be zero.

Details About Intrinsics for Half Floats

There are four intrinsics for converting half-floats to 32-bit floats and 32-bit floats to half-floats. The prototypes for these half-float conversion intrinsics are in the `emmintrin.h` file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

`float _cvtsh_ss(unsigned short x);`

This intrinsic takes a half-float value, `x`, and converts it to a 32-bit float value, which is returned.

`unsigned short _cvtss_sh(float x, int imm);`

This intrinsic takes a 32-bit float value, `x`, and converts it to a half-float value, which is returned.

`__m128 _mm_cvtph_ps(__m128i x);`

This intrinsic takes four packed half-float values and converts them to four 32-bit float values, which are returned. The upper 64-bits of `x` are ignored. The lower 64-bits are taken as four 16-bit float values for conversion.

`__m128i _mm_cvtps_ph(_m128 x, int imm);`

This intrinsic takes four packed 32-bit float values and converts them to four half-float values, which are returned. The upper 64-bits in the returned result are all zeros. The lower 64-bits contain the four packed 16-bit float values.

Intrinsics for Short Vector Math Library Operations (SVML)

The compiler provides short vector math library (SVML) intrinsics to compute vector math functions. These intrinsics are available for IA-32 and Intel® 64 architectures running on supported operating systems. The prototypes for the SVML intrinsics are available in the `immintrin.h` file.

To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

The SVML intrinsics do not have any corresponding instructions.

The SVML intrinsics are vector variants of corresponding scalar math operations using `__m128`, `__m128d`, `__m256`, `__m256d`, and `__m256i` data types. They take packed vector arguments, perform the operation on each element of the packed vector argument, and return a packed vector result.

For example, the argument to the `_mm_sin_ps` intrinsic is a packed 128-bit vector of four 32-bit precision floating point numbers. The intrinsic computes the sine of each of these four numbers and returns the four results in a packed 128-bit vector.

Using SVML intrinsics is faster than repeatedly calling the scalar math functions. However, the intrinsics differ from the scalar functions in accuracy.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

This section also includes information about 512-bit intrinsics for SVML.

Intrinsics for Division Operations (512-bit)

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction

`_mm512_div_pd`, `_mm512_mask_div_pd`, `_mm512_maskz_div_pd`
 	
`_mm512_div_round_pd`, `_mm512_mask_div_round_pd`, `_mm512_maskz_div_round_pd`
	Calculates quotient of rounded division operation of packed float64 elements.	`VDIVPD`

`_mm512_div_ps`, `_mm512_mask_div_ps`, `_mm512_maskz_div_ps`	Calculates quotient of rounded division operation of packed float32 elements.	`VDIVPS`

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
_mm512_div_round_ps, _mm512_mask_div_round_ps, _mm512_maskz_div_round_ps		
_mm_mask_div_sd, _mm_maskz_div_sd _mm_div_round_sd, _mm_mask_div_round_sd, _mm_maskz_div_round_sd	Calculates quotient of rounded division operation of scalar float64 elements.	VDIVSD
_mm_mask_div_ss, _mm_maskz_div_ss _mm_div_round_ss, _mm_mask_div_round_ss, _mm_maskz_div_round_ss	Calculates quotient of rounded division operation of scalar float32 elements.	VDIVSS

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result
round	Rounding control values; these can be one of the following (along with the `sae` suppress all exceptions flag): • `_MM_FROUND_TO_NEAREST_INT` - rounds to nearest even • `_MM_FROUND_TO_NEG_INF` - rounds to negative infinity • `_MM_FROUND_TO_POS_INF` - rounds to positive infinity • `_MM_FROUND_TO_ZERO` - rounds to zero • `_MM_FROUND_CUR_DIRECTION` - rounds using default from MXCSR register

_mm512_div_pd

```
extern __m512d __cdecl _mm512_div_pd(__m512d a, __m512d b);
```

Divides packed float64 elements in *a* by packed elements in *b*, and stores the result.

_mm512_mask_div_pd

```
extern __m512d __cdecl _mm512_mask_div_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
```

Divides packed float64 elements in *a* by packed elements in *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_div_pd

```
extern __m512d __cdecl _mm512_maskz_div_pd(__mmask8 k, __m512d a, __m512d b);
```

Divides packed float64 elements in *a* by packed elements in *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_div_round_pd

```
extern __m512d __cdecl _mm512_div_round_pd(__m512d a, __m512d b, int round);
```

Divides packed float64 elements in *a* by packed elements in *b*, and stores the result.

_mm512_mask_div_round_pd

```
extern __m512d __cdecl _mm512_mask_div_round_pd(__m512d src, __mmask8 k, __m512d a, __m512d b,
int round);
```

Divides packed float64 elements in *a* by packed elements in *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_div_round_pd

```
extern __m512d __cdecl _mm512_maskz_div_round_pd(__mmask8 k, __m512d a, __m512d b, int round);
```

Divides packed float64 elements in *a* by packed elements in *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_div_ps

```
extern __m512 __cdecl _mm512_div_ps(__m512 a, __m512 b);
```

Divides packed float32 elements in *a* by packed elements in *b*, and stores the result.

_mm512_mask_div_ps

```
extern __m512 __cdecl _mm512_mask_div_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);
```

Divides packed float32 elements in *a* by packed elements in *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_div_ps

```
extern __m512 __cdecl _mm512_maskz_div__ps(__mmask16 k, __m512 a, __m512 b);
```

Divides packed float32 elements in *a* by packed elements in *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm512_div_round_ps

```
extern __m512 __cdecl _mm512_div_round_ps(__m512 a, __m512 b, int round);
```

Divides packed float32 elements in *a* by packed elements in *b*, and stores the result.

_mm512_mask_div_round_ps

```
extern __m512 __cdecl _mm512_mask_div_round_ps(__m512 src, __mmask16 k, __m512 a, __m512 b, int
round);
```

Divides packed float32 elements in *a* by packed elements in *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_maskz_div_round_ps

```
extern __m512 __cdecl _mm512_maskz_div_round_ps(__mmask16 k, __m512 a, __m512 b, int round);
```

Divides packed float32 elements in *a* by packed elements in *b*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

_mm_mask_div_sd

```
extern __m128d __cdecl _mm_mask_div_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
```

Divides lower float64 element in *a* by lower float64 element in *b*, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper element from *a* to upper destination element.

_mm_maskz_div_sd

```
extern __m128d __cdecl _mm_maskz_div_sd(__mmask8 k, __m128d a, __m128d b);
```

Divides lower float64 element in *a* by lower float64 element in *b*, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper element from *a* to upper destination element.

_mm_div_round_sd

```
extern __m128d __cdecl _mm_div_round_sd(__m128d a, __m128d b, int round);
```

Divides lower float64 element in *a* by lower float64 element in *b*, stores the result in lower destination element, and copies upper element from *a* to upper destination element.

_mm_mask_div_round_sd

```
extern __m128d __cdecl _mm_mask_div_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b, int
round);
```

Divides lower float64 element in *a* by lower float64 element in *b*, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper element from *a* to upper destination element.

_mm_maskz_div_round_sd

```
extern __m128d __cdecl _mm_maskz_div_round_sd(__mmask8 k, __m128d a, __m128d b, int round);
```

Divides lower float64 element in *a* by lower float64 element in *b*, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper element from *a* to upper destination element.

_mm_div_round_ss

```
extern __m128 __cdecl _mm_div_round_ss(__m128 a, __m128 b, int round);
```

Divides lower float32 element in *a* by lower float32 element in *b*, stores the result in lower destination element, and copies upper three packed elements from *a* to upper destination elements.

_mm_mask_div_round_ss

```
extern __m128 __cdecl _mm_mask_div_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b, int
round);
```

Divides lower float32 element in *a* by lower float32 element in *b*, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

_mm_maskz_div_round_ss

```
extern __m128 __cdecl _mm_maskz_div_round_ss(__mmask8 k, __m128 a, __m128 b, int round);
```

Divides lower float32 element in *a* by lower float32 element in *b*, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

_mm_mask_div_ss

```
extern __m128 __cdecl _mm_mask_div_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);
```

Divides lower float32 element in *a* by lower float32 element in *b*, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

_mm_maskz_div_ss

```
extern __m128 __cdecl _mm_maskz_div_ss(__mmask8 k, __m128 a, __m128 b);
```

Divides lower float32 element in *a* by lower float32 element in *b*, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

Intrinsics for Division Operations

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_div_epi8/ _mm256_div_epi8

Calculates quotient of a division operation. Vector variant of `div()` function for signed 8-bit integer arguments.

Syntax

```
extern __m128i _mm_div_epi8(__m128i v1, __m128i v2);
extern __m256i _mm256_div_epi8(__m256i v1, __m256i v2);
```

Parameters

v1	signed integer source vector containing the dividends
v2	signed integer source vector containing the divisors

Description

Calculates the quotient by dividing value of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_div_epi16/ _mm256_div_epi16

Calculates quotient of a division operation. Vector variant of `div()` function for signed 16-bit integer arguments.

Syntax

```
extern __m128i _mm_div_epi16(__m128i v1, __m128i v2);
```

```
extern __m256i _mm256_div_epi16(__m256i v1, __m256i v2);
```

Parameters

v1	signed integer source vector containing the dividends
v2	signed integer source vector containing the divisors

Description

Calculates the quotient by dividing value of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_div_epi32/ _mm256_div_epi32

Calculates quotient of a division operation. Vector variant of `div()` function for signed 32-bit integer arguments.

Syntax

```
extern __m128i _mm_div_epi32(__m128i v1, __m128i v2);
```

```
extern __m256i _mm256_div_epi32(__m256i v1, __m256i v2);
```

Parameters

v1	signed integer source vector containing the dividends
v2	signed integer source vector containing the divisors

Description

Calculates the quotient by dividing value of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_div_epi64/ _mm256_div_epi64

Calculates quotient of a division operation. Vector variant of `div()` function for signed 64-bit integer arguments.

Syntax

```
extern __m128i _mm_div_epi64(__m128i v1, __m128i v2);
extern __m256i _mm256_div_epi64(__m256i v1, __m256i v2);
```

Parameters

v1	signed integer source vector containing the dividends
v2	signed integer source vector containing the divisors

Description

Calculates the quotient by dividing value of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_div_epu8/ _mm256_div_epu8

Calculates quotient of a division operation. Vector variant of `div()` function for unsigned 8-bit integer arguments.

Syntax

```
extern __m128i _mm_div_epu8(__m128i v1, __m128i v2);
extern __m256i _mm256_div_epu8(__m256i v1, __m256i v2);
```

Parameters

v1	unsigned integer source vector containing the dividends
v2	unsigned integer source vector containing the divisors

Description

Calculates the quotient by dividing value of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_div_epu16/ _mm256_div_epu16

Calculates quotient of a division operation. Vector variant of `div()` function for unsigned 16-bit integer arguments.

Syntax

```
extern __m128i _mm_div_epu16(__m128i v1, __m128i v2);
```

```
extern __m256i _mm256_div_epu16(__m256i v1, __m256i v2);
```

Parameters

v1	unsigned integer source vector containing the dividends
v2	unsigned integer source vector containing the divisors

Description

Calculates the quotient by dividing value of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_div_epu32/ _mm256_div_epu32

Calculates quotient of a division operation. Vector variant of `div()` function for unsigned 32-bit integer arguments.

Syntax

```
extern __m128i _mm_div_epu32(__m128i v1, __m128i v2);
```

```
extern __m256i _mm256_div_epu32(__m256i v1, __m256i v2);
```

Parameters

v1	unsigned integer source vector containing the dividends
v2	unsigned integer source vector containing the divisors

Description

Calculates the quotient by dividing value of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_div_epu64/ _mm256_div_epu64

Calculates quotient of a division operation. Vector variant of `div()` function for unsigned 64-bit integer arguments.

Syntax

```
extern __m128i _mm_div_epu64(__m128i v1, __m128i v2);
```

```
extern __m256i _mm256_div_epu64(__m256i v1, __m256i v2);
```

Parameters

v1	unsigned integer source vector containing the dividends
v2	unsigned integer source vector containing the divisors

Description

Calculates the quotient by dividing value of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_rem_epi8/ _mm256_rem_epi8

Calculates remainder of a division operation. Vector variant of `rem()` function for signed 8-bit integer arguments.

Syntax

```
extern __m128i _mm_rem_epi8(__m128i v1, __m128i v2);
extern __m256i _mm256_rem_epi8(__m256i v1, __m256i v2);
```

Parameters

v1	signed integer source vector containing the dividends
v2	signed integer source vector containing the divisors

Description

Calculates the remainder from division of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_rem_epi16/ _mm256_rem_epi16

Calculates remainder of a division operation. Vector variant of `rem()` function for signed 16-bit integer arguments.

Syntax

```
extern __m128i _mm_rem_epi16(__m128i v1, __m128i v2);
extern __m256i _mm256_rem_epi16(__m256i v1, __m256i v2);
```

Parameters

v1	signed integer source vector containing the dividends
v2	signed integer source vector containing the divisors

Description

Calculates the remainder from division of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_rem_epi32/ _mm256_rem_epi32

Calculates remainder of a division operation. Vector variant of `rem()` function for signed 32-bit integer arguments.

Syntax

```
extern __m128i _mm_rem_epi32(__m128i v1, __m128i v2);
```

```
extern __m256i _mm256_rem_epi32(__m256i v1, __m256i v2);
```

Parameters

v1	signed integer source vector containing the dividends
v2	signed integer source vector containing the divisors

Description

Calculates the remainder from division of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_rem_epi64/ _mm256_rem_epi64

Calculates remainder of a division operation. Vector variant of `rem()` function for signed 64-bit integer arguments.

Syntax

```
extern __m128i _mm_rem_epi64(__m128i v1, __m128i v2);
```

```
extern __m256i _mm256_rem_epi64(__m256i v1, __m256i v2);
```

Parameters

v1	signed integer source vector containing the dividends
v2	signed integer source vector containing the divisors

Description

Calculates the remainder from division of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_rem_epu8/ _mm256_rem_epu8

Calculates remainder of a division operation. Vector variant of `rem()` function for unsigned 8-bit integer arguments.

Syntax

```
extern __m128i _mm_rem_epu8(__m128i v1, __m128i v2);
```

```
extern __m256i _mm256_rem_epu8(__m256i v1, __m256i v2);
```

Parameters

v1	unsigned integer source vector containing the dividends
v2	unsigned integer source vector containing the divisors

Description

Calculates the remainder from division of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_rem_epu16/ _mm256_rem_epu16

Calculates remainder of a division operation. Vector variant of `rem()` function for unsigned 16-bit integer arguments.

Syntax

```
extern __m128i _mm_rem_epu16(__m128i v1, __m128i v2);
```

```
extern __m256i _mm256_rem_epu16(__m256i v1, __m256i v2);
```

Parameters

v1	unsigned integer source vector containing the dividends

v2 unsigned integer source vector containing the divisors

Description

Calculates the remainder from division of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_rem_epu32/ _mm256_rem_epu32

Calculates remainder of a division operation. Vector variant of `rem()` function for unsigned 32-bit integer arguments.

Syntax

```
extern __m128i _mm_rem_epu32(__m128i v1, __m128i v2);
```

```
extern __m256i _mm256_rem_epu32(__m256i v1, __m256i v2);
```

Parameters

v1 unsigned integer source vector containing the dividends

v2 unsigned integer source vector containing the divisors

Description

Calculates the remainder from division of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_rem_epu64/ _mm256_rem_epu64

Calculates remainder of a division operation. Vector variant of `rem()` function for unsigned 64-bit integer arguments.

Syntax

```
extern __m128i _mm_rem_epu64(__m128i v1, __m128i v2);
```

```
extern __m256i _mm256_rem_epu64(__m256i v1, __m256i v2);
```

Parameters

v1	unsigned integer source vector containing the dividends
v2	unsigned integer source vector containing the divisors

Description

Calculates the remainder from division of `v1` vector elements by corresponding `v2` vector elements.

Returns

Returns the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Intrinsics for Error Function Operations (512-bit)

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_cdfnorm_pd`, `_mm512_mask_cdfnorm_pd`	Calculates cumulative distribution function for float64 vector elements.	**None.**
`_mm512_cdfnorm_ps`, `_mm512_mask_cdfnorm_ps`	Calculates cumulative distribution function for float32 vector elements.	**None.**
`_mm512_cdfnorminv_pd`, `_mm512_mask_cdfnorminv_pd`	Calculates inverse cumulative distribution function for float64 vector elements.	**None.**
`_mm512_cdfnorminv_ps`, `_mm512_mask_cdfnorminv_ps`	Calculates inverse cumulative distribution function for float32 vector elements.	**None.**
`_mm512_erf_pd`, `_mm512_mask_erf_pd`	Calculates error function for float64 vector elements.	**None.**
`_mm512_erf_ps`, `_mm512_mask_erf_ps`	Calculates error function for float32 vector elements.	**None.**
`_mm512_erfc_pd`, `_mm512_mask_erfc_pd`	Calculates complementary error function for float64 vector elements.	**None.**

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_erfc_ps`, `_mm512_mask_erfc_ps`	Calculates complementary error function for float32 vector elements.	**None.**
`_mm512_erfinv_pd`, `_mm512_mask_erfinv_pd`	Calculates inverse error function for float64 vector elements.	**None.**
`_mm512_erfinv_ps`, `_mm512_mask_erfinv_ps`	Calculates inverse error function for float32 vector elements.	**None.**
`_mm512_erfcinv_pd`, `_mm512_mask_ercfinv_pd`	Calculates inverse complementary error function for float64 vector elements.	**None.**
`_mm512_erfcinv_ps`, `_mm512_mask_ercfinv_ps`	Calculates inverse complementary error function for float32 vector elements.	**None.**

variable	definition
k	writemask used as a selector
a	first source vector element
src	source element to use based on writemask result

_mm512_cdfnorm_pd

```
extern __m512d __cdecl _mm512_cdfnorm_pd(__m512d a);
```

Computes normalized central distribution function for float64 elements in *a*, and stores the result.

_mm512_mask_cdfnorm_pd

```
extern __m512d __cdecl _mm512_mask_cdfnorm_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes normalized central distribution function for float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_cdfnorm_ps

```
extern __m512 __cdecl _mm512_cdfnorm_ps(__m512 a);
```

Computes normalized central distribution function for float32 elements in *a*, and stores the result.

_mm512_mask_cdfnorm_ps

```
extern __m512 __cdecl _mm512_mask_cdfnorm_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes normalized central distribution function for float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_cdfnorminv_pd

```
extern __m512d __cdecl _mm512_cdfnorminv_pd(__m512d a);
```

Computes inverse normalized central distribution function for float64 elements in *a*, and stores the result.

_mm512_mask_cdfnorminv_pd

```
extern __m512d __cdecl _mm512_mask_cdfnorminv_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes inverse normalized central distribution function for float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_cdfnorminv_ps

```
extern __m512 __cdecl _mm512_cdfnorminv_ps(__m512 a);
```

Computes inverse normalized central distribution function for float32 elements in *a*, and stores the result.

_mm512_mask_cdfnorminv_ps

```
extern __m512 __cdecl _mm512_mask_cdfnorminv_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes inverse normalized central distribution function for float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_erf_pd

```
extern __m512d __cdecl _mm512_erf_pd(__m512d a);
```

Computes error function of packed float64 elements in *a*, and stores the result.

_mm512_mask_erf_pd

```
extern __m512d __cdecl _mm512_mask_erf_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes error function of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_erf_ps

```
extern __m512 __cdecl _mm512_erf_ps(__m512 a);
```

Computes error function of packed float32 elements in *a*, and stores the result.

_mm512_mask_erf_ps

```
extern __m512 __cdecl _mm512_mask_erf_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes error function of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_mask_erfc_pd

```
extern __m512d __cdecl _mm512_erfc_pd(__m512d a);
```

Computes complex error function of packed float64 elements in *a*, and stores the result.

_mm512_mask_erfc_pd

```
extern __m512d __cdecl _mm512_mask_erfc_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes complex error function of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_erfc_ps

```
extern __m512 __cdecl _mm512_erfc_ps(__m512 a);
```

Computes complex error function of packed float32 elements in *a*, and stores the result.

_mm512_mask_erfc_ps

```
extern __m512 __cdecl _mm512_mask_erfc_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes complex error function of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_erfinv_pd

```
extern __m512d __cdecl _mm512_erfinv_pd(__m512d a);
```

Calculates the inverse error function of float64 vector *a* elements.

_mm512_mask_erfinv_pd

```
extern __m512d __cdecl _mm512_mask_erfinv_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes inverse error function of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_erfinv_ps

```
extern __m512 __cdecl _mm512_erfinv_ps(__m512 a);
```

Computes inverse error function of packed float32 elements in *a*, and stores the result.

_mm512_mask_erfinv_ps

```
extern __m512 __cdecl _mm512_mask_erfinv_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes inverse error function of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_erfcinv_pd

```
extern __m512d __cdecl _mm512_erfcinv_pd(__m512d a);
```

Computes inverse complex error function of packed float64 elements in *a*, and stores the result.

_mm512_mask_erfcinv_pd

```
extern __m512d __cdecl _mm512_mask_erfcinv_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes inverse complex error function of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_erfcinv_ps

```
extern __m512 __cdecl _mm512_erfcinv_ps(__m512 a);
```

Computes inverse complex error function of packed float32 elements in *a*, and stores the result.

_mm512_mask_erfcinv_ps

```
extern __m512 __cdecl _mm512_mask_erfcinv_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes inverse complex error function of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

Intrinsics for Error Function Operations

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cdfnorminv_pd, _mm256_cdfnorminv_pd

Calculates inverse cumulative distribution function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_cdfnorminv_pd(__m128d v1);
extern __m256d _mm256_cdfnorminv_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Returns the inverse cumulative distribution function of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cdfnorminv_ps, _mm256_cdfnorminv_ps

Calculates inverse cumulative distribution function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_cdfnorminv_ps(__m128 v1);
extern __m256 _mm256_cdfnorminv_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Returns the inverse cumulative distribution function of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_erf_pd, _mm256_erf_pd

Calculates error function. Vector variant of erf(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_erf_pd(__m128d v1);
```

```
extern __m256d _mm256_erf_pd(__m256d v1);
```

Arguments

v1	float64 vector used for the operation

Description

Calculates error function of v1 elements, which is defined as:

```
erf(x) = 2/sqrt(pi)* integral from 0 to x of exp(-t*t) dt
```

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_erf_ps, _mm256_erf_ps

Calculates error function. Vector variant of erf(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_erf_ps(__m128 v1);
```

```
extern __m256 _mm256_erf_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates error function of v1 elements, which is defined as:

```
erf(x) = 2/sqrt(pi)* integral from 0 to x of exp(-t*t) dt
```

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_erfc_pd, _mm256_erfc_pd

Calculates complementary error function. Vector variant of erfc(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_erfc_pd(__m128d v1);
extern __m256d _mm256_erfc_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the complementary error function of vector *v1* elements, which is defined as:

```
1.0 - erf(x)
```

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_erfc_ps, _mm256_erfc_ps

Calculates complementary error function. Vector variant of erfc(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_erfc_ps(__m128 v1);
```

```
extern __m256 _mm256_erfc_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the complementary error function of vector *v1* elements, which is

```
1.0 - erf(x)
```

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_erfinv_pd, _mm256_erfinv_pd

Calculates inverse error function. Vector variant of erfinv(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_erfinv_pd(__m128d v1);
```

```
extern __m256d _mm256_erfinv_pd(__m256d v1);
```

Arguments

v1	float64 vector used for the operation

Description

Calculates the inverse error function of *v1* elements, which is defined as:

```
1 / erf(x)
```

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_erfinv_ps, _mm256_erfinv_ps

Calculates inverse error function. Vector variant of erfinv(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_erfinv_ps(__m128 v1);
```

```
extern __m256 _mm256_erfinv_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the inverse error function of *v1* elements, which is defined as:

```
1 / erf(x)
```

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Intrinsics for Exponential Operations (512-bit)

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_pow_pd`, `_mm512_mask_pow_pd`	Calculates exponential value of float64 vector elements raised to the power of other float64 vector elements.	**None.**
`_mm512_pow_ps`, `_mm512_mask_mm512_pow_ps`	Calculates exponential value of float32 vector elements raised to the power of other float32 vector elements.	**None.**
`_mm512_exp10_pd`, `_mm512_mask_mm512_exp10_pd`	Calculates base-10 exponential value of float64 vector elements.	**None.**
`_mm512_exp10_ps`, `_mm512_mask_mm512_exp10_ps`	Calculates base-10 exponential value of float32 vector elements.	**None.**
`_mm512_exp2_pd`, `_mm512_mask_mm512_exp2_pd`	Calculates base-2 exponential value of float64 vector elements.	**None.**

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_exp2_ps`, `_mm512_mask_mm512_exp2_ps`	Calculates base-2 exponential value of float32 vector elements.	**None.**
`_mm512_exp_pd`, `_mm512_mask_mm512_exp_pd`	Calculates base-e exponential value of float64 vector elements.	**None.**
`_mm512_exp_ps`, `_mm512_mask_mm512_exp_ps`	Calculates base-e exponential value of float32 vector elements.	**None.**
`_mm512_expm1_pd`, `_mm512_mask_mm512_expm1_pd`	Calculates base-e exponential value of float64 vector elements minus one.	**None.**
`_mm512_expm1_ps`, `_mm512_mask_mm512_expm1_ps`	Calculates base-e exponential value of float32 vector elements minus one.	**None.**

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result

_mm512_pow_pd

```
extern __m512d __cdecl _mm512_pow_pd(__m512d a, __m512d b);
```

Calculates the exponential value of each float64 vector *a* element raised to the power of the corresponding vector *b* element, and stores the result.

_mm512_mask_pow_pd

```
extern __m512d __cdecl _mm512_mask_pow_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
```

Calculates the exponential value of each float64 vector *a* element raised to the power of the corresponding vector *b* element, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_pow_ps

```
extern __m512 __cdecl _mm512_pow_ps(__m512 a, __m512 b);
```

Calculates the exponential value of each float32 vector *a* element raised to the power of the corresponding vector *b* element, and stores the result.

_mm512_mask_pow_ps

```
extern __m512 __cdecl _mm512_mask_pow_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);
```

Calculates the exponential value of each float32 vector *a* element raised to the power of the corresponding vector *b* element, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_exp10_pd

```
extern __m512d __cdecl _mm512_exp10_pd(__m512d a);
```

Computes the base-10 exponent of packed float64 elements in *a*, and stores the result.

_mm512_mask_exp10_pd

```
extern __m512d __cdecl _mm512_mask_exp10_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the base-10 exponent of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_exp10_ps

```
extern __m512 __cdecl _mm512_exp10_ps(__m512 a);
```

Computes the base-10 exponent of packed float32 elements in *a*, and stores the result.

_mm512_mask_exp10_ps

```
extern __m512 __cdecl _mm512_mask_exp10_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the base-10 exponent of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_exp2_pd

```
extern __m512d __cdecl _mm512_exp2_pd(__m512d a);
```

Computes the base-2 exponent of packed float64 elements in *a*, and stores the result.

_mm512_mask_exp2_pd

```
extern __m512d __cdecl _mm512_mask_exp2_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the base-2 exponent of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_exp2_ps

```
extern __m512 __cdecl _mm512_exp2_ps(__m512 a);
```

Computes the base-2 exponent of packed float32 elements in *a*, and stores the result.

_mm512_mask_exp2_ps

```
extern __m512 __cdecl _mm512_mask_exp2_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the base-2 exponent of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_exp_pd

```
extern __m512d __cdecl _mm512_exp_pd(__m512d a);
```

Calculates the exponential value of e (base of natural logarithms) raised to the power of float64 vector *a* elements.

_mm512_mask_exp_pd

```
extern __m512d __cdecl _mm512_mask_exp_pd(__m512d src, __mmask8 k, __m512d a);
```

Calculates the exponential value of e (base of natural logarithms) raised to the power of float64 vector *a* elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_exp_ps

```
extern __m512 __cdecl _mm512_exp_ps(__m512 a);
```

Calculates the exponential value of e (base of natural logarithms) raised to the power of float32 vector *a* elements.

_mm512_mask_exp_ps

```
extern __m512 __cdecl _mm512_mask_exp_ps(__m512 src, __mmask16 k, __m512 a);
```

Calculates the exponential value of e (base of natural logarithms) raised to the power of float32 vector *a* elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_expm1_pd

```
extern __m512d __cdecl _mm512_expm1_pd(__m512d a);
```

Calculates exponential value of e (base of natural logarithms), raised to the power of float64 vector *a* elements minus one.

_mm512_mask_expm1_pd

```
extern __m512d __cdecl _mm512_mask_expm1_pd(__m512d src, __mmask8 k, __m512d a);
```

Calculates exponential value of e (base of natural logarithms), raised to the power of float64 vector *a* elements minus one, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_expm1_ps

```
extern __m512 __cdecl _mm512_expm1_ps(__m512 a);
```

Calculates exponential value of e (base of natural logarithms), raised to the power of float32 vector *a* elements minus one.

_mm512_mask_expm1_ps

```
extern __m512 __cdecl _mm512_mask_expm1_ps(__m512 src, __mmask16 k, __m512 a);
```

Calculates exponential value of e (base of natural logarithms), raised to the power of float32 vector *a* elements minus one, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

Intrinsics for Exponential Operations

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_exp2_pd, _mm256_exp2_pd

Calculates exponential value of 2. Vector variant of exp2(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_exp2_pd(__m128d v1);
```

```
extern __m256d _mm256_exp2_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the exponential value of 2 raised to the power of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_exp2_ps, _mm256_exp2_ps

Calculates exponential value of 2. Vector variant of exp2(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_exp2_ps(__m128 v1);
```

```
extern __m256 _mm256_exp2_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the exponential value of 2 raised to the power of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_exp_pd, _mm256_exp_pd

Calculates exponential value of e (base of natural logarithms). Vector variant of exp(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_exp_pd(__m128d v1);
```

```
extern __m256d _mm256_exp_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the exponential value of *e* (base of natural logarithms) raised to the power of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_exp_ps, _mm256_exp_ps

Calculates exponential value of e (base of natural logarithms). Vector variant of exp(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_exp_ps(__m128 v1);
```

```
extern __m256 _mm256_exp_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the exponential value of *e* (base of natural logarithms) raised to the power of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_exp10_pd, _mm256_exp10_pd

Calculates exponential value of 10. Vector variant of exp(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_exp10_pd(__m128d v1);
```

```
extern __m256d _mm256_exp10_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates 10 raised to the power of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_exp10_ps, _mm256_exp10_ps

Calculates exponential value of 10. Vector variant of exp(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_exp10_ps(__m128 v1);
```

```
extern __m256 _mm256_exp10_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates 10 raised to the power of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_expm1_pd, _mm256_expm1_pd

Calculates exponential value of e (base of natural logarithms), raised to the power of vector elements minus 1. Vector variant of expm1(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_expm1_pd(__m128d v1);
```

```
extern __m256d _mm256_expm1_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates exponential value of *e* (base of natural logarithms), raised to the power of vector elements minus 1.

$$e^{(x)} - 1$$

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_expm1_ps, _mm256_expm1_ps

Calculates exponential value of e (base of natural logarithms), raised to the power of vector elements minus 1. Vector variant of expm1(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_expm1_ps(__m128 v1);
```

```
extern __m256 _mm256_expm1_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates exponential value of *e* (base of natural logarithms), raised to the power of vector elements minus 1.

```
e^(x) - 1
```

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cexp_ps, _mm256_cexp_ps

Calculates complex exponential value of e (base of natural logarithms). Vector variant of exp(x) function for a 128-bit/256-bit vector argument of _Complex float32 values.

Syntax

```
extern __m128 _mm_cexp_ps(__m128 v1);
```

```
extern __m256 _mm256_cexp_ps(__m256 v1);
```

Arguments

v1	vector with _Complex float32 values

Description

Calculates the complex exponential value of *e* (base of natural logarithms) raised to the power of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_pow_pd, _mm256_pow_pd

Calculates exponential value of one argument raised to the other argument. Vector variant of pow(x, y) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_pow_pd(__m128d v1, __m128d v2);
```

```
extern __m256d _mm256_pow_pd(__m256d v1, __m256d v2);
```

Arguments

v1	vector with float64 values
v2	vector with float64 values

Description

Calculates the exponential value of each vector *v1* element raised to the power of the corresponding vector *v2* element.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_pow_ps, _mm256_pow_ps

Calculates exponential value of one argument raised to the other argument. Vector variant of pow(x, y) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_pow_ps(__m128 v1, __m128 v2);
```

```
extern __m256 _mm256_pow_ps(__m256 v1, __m256 v2);
```

Arguments

v1	vector with float32 values
v2	vector with float32 values

Description

Calculates the exponential value of each vector *v1* element raised to the power of the corresponding vector *v2* element.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_hypot_pd, _mm256_hypot_pd

Computes the length of the hypotenuse of a right angled triangle. Vector variant of hypot(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_hypot_pd(__m128d v1, __m128d v2);
```

```
extern __m256d _mm256_hypot_pd(__m256d v1, __m256d v2);
```

Arguments

v1	vector with float64 values
v2	vector with float64 values

Description

Computes the length of the hypotenuse of a right angled triangle with sides *v1* and *v2*, defined by:

$$\mathrm{sqrt}\ (v1^2 + v2^2)$$

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_hypot_ps, _mm256_hypot_ps

Computes the length of the hypotenuse of a right angled triangle. Vector variant of hypot(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_hypot_ps(__m128 v1, __m128 v2);
```

```
extern __m256 _mm256_hypot_ps(__m256 v1, __m256 v2);
```

Arguments

v1	vector with float32 values
v2	vector with float32 values

Description

Computes the length of the hypotenuse of a right angled triangle with sides *v1* and *v2*, defined by:

$$\mathrm{sqrt}\ (v1^2 + v2^2)$$

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Intrinsics for Logarithmic Operations (512-bit)

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_log10_pd`, `_mm512_mask_log10_pd`	Calculates base-10 logarithm.	**None.**
`_mm512_log10_ps`, `_mm512_mask_log10_ps`	Calculates base-10 logarithm.	**None.**

`_mm512_logb_ps`, `_mm512_mask_logb_ps`	Calculates signed exponent.	**None.**

variable	definition
k	zeromask used as a selector
k	writemask used as a selector
a	first source vector element
b	second source vector element
c	third source vector element
src	source element

_mm512_log10_pd

```
extern __m512d __cdecl _mm512_log10_pd(__m512d a);
```

Calculates the base-10 logarithm of vector *a* elements.

_mm512_mask_log10_pd

```
extern __m512d __cdecl _mm512_mask_log10_pd(__m512d src, __mmask8 k, __m512d a);
```

Calculates the base-10 logarithm of vector *a* elements.

_mm512_log10_ps

```
extern __m512 __cdecl _mm512_log10_ps(__m512 a);
```

Calculates the base-10 logarithm of vector *a* elements.

_mm512_mask_log10_ps

```
extern __m512 __cdecl _mm512_mask_log10_ps(__m512 src, __mmask16 k, __m512 a);
```

Calculates the base-10 logarithm of vector *a* elements.

_mm512_log1p_pd

```
extern __m512d __cdecl _mm512_log1p_pd(__m512d a);
```

Calculates the natural logarithm of vector *a* elements, defined by: `ln` $^{(v1 + 1)}$

_mm512_mask_log1p_pd

```
extern __m512d __cdecl _mm512_mask_log1p_pd(__m512d src, __mmask8 k, __m512d a);
```

Calculates the natural logarithm of vector *a* elements, defined by: `ln` $^{(v1 + 1)}$

_mm512_log1p_ps

```
extern __m512 __cdecl _mm512_log1p_ps(__m512 a);
```

Calculates the natural logarithm of vector *a* elements, defined by: `ln` $^{(v1 + 1)}$

_mm512_mask_log1p_ps

```
extern __m512 __cdecl _mm512_mask_log1p_ps(__m512 src, __mmask16 k, __m512 a);
```

Calculates the natural logarithm of vector *a* elements, defined by: `ln` $^{(v1 + 1)}$

_mm512_log2_pd

```
extern __m512d __cdecl _mm512_log2_pd(__m512d a);
```

Calculates the base-2 logarithm of vector *a* elements.

_mm512_mask_log2_pd

```
extern __m512d __cdecl _mm512_mask_log2_pd(__m512d src, __mmask8 k, __m512d a);
```

Calculates the base-2 logarithm of vector *a* elements.

_mm512_log_pd

```
extern __m512d __cdecl _mm512_log_pd(__m512d a);
```

Calculates the natural (base-e) logarithm of vector *a* elements.

_mm512_mask_log_pd

```
extern __m512d __cdecl _mm512_mask_log_pd(__m512d src, __mmask8 k, __m512d a);
```

Calculates the natural (base-e) logarithm of vector *a* elements.

_mm512_log_ps

```
extern __m512 __cdecl _mm512_log_ps(__m512 a);
```

Calculates the natural (base-e) logarithm of vector *a* elements.

_mm512_mask_log_ps

```
extern __m512 __cdecl _mm512_mask_log_ps(__m512 src, __mmask16 k, __m512 a);
```

Calculates the natural (base-e) logarithm of vector *a* elements.

_mm512_logb_pd

```
extern __m512d __cdecl _mm512_logb_pd(__m512d a);
```

Calculates the signed exponent of vector *a* elements.

_mm512_mask_logb_pd

```
extern __m512d __cdecl _mm512_mask_logb_pd(__m512d src, __mmask8 k, __m512d a);
```

Calculates the signed exponent of vector *a* elements.

_mm512_logb_ps

```
extern __m512 __cdecl _mm512_logb_ps(__m512 a);
```

Calculates the signed exponent of vector *a* elements.

_mm512_mask_logb_ps

```
extern __m512 __cdecl _mm512_mask_logb_ps(__m512 src, __mmask16 k, __m512 a);
```

Calculates the signed exponent of vector *a* elements.

Intrinsics for Logarithmic Operations

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_log2_pd, _mm256_log2_pd

Calculates base-2 logarithm. Vector variant of log2(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_log2_pd(__m128d v1);
```

```
extern __m256d _mm256_log2_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the base-2 logarithm of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_log2_ps, _mm256_log2_ps

Calculates base-2 logarithm. Vector variant of log2(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_log2_ps(__m128 v1);
extern __m256 _mm256_log2_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the base-2 logarithm of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_log10_pd, _mm256_log10_pd

Calculates base-10 logarithm. Vector variant of log10(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_log10_pd(__m128d v1);
extern __m256d _mm256_log10_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the base-10 logarithm of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_log10_ps, _mm256_log10_ps

Calculates base-10 logarithm. Vector variant of log10(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_log10_ps(__m128 v1);
extern __m256 _mm256_log10_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the base-10 logarithm of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_log_pd, _mm256_log_pd

Calculates natural logarithm. Vector variant of log(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_log_pd(__m128d v1);
extern __m256d _mm256_log_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the natural logarithm of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_log_ps, _mm256_log_ps

Calculates natural logarithm. Vector variant of log(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_log_ps(__m128 v1);
extern __m256 _mm256_log_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the natural logarithm of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_logb_pd, _mm256_logb_pd

Calculates signed exponent. Vector variant of logb(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_logb_pd(__m128d v1);
extern __m256d _mm256_logb_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Returns the signed exponent for vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_logb_ps, _mm256_logb_ps

Calculates signed exponent. Vector variant of logb(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_logb_ps(__m128 v1);
```

```
extern __m256 _mm256_logb_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Returns the signed exponent for vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_log1p_pd, _mm256_log1p_pd

Calculates natural logarithm. Vector variant of log1p(x) function for a 128-bit/256-bit vector arguments with float64 values.

Syntax

```
extern __m128d _mm_log1p_pd(__m128d v1);
```

```
extern __m256d _mm256_log1p_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Returns the natural logarithm of vector *v1* elements, defined by:

```
ln (v1 + 1)
```

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_log1p_ps, _mm256_log1p_ps

Calculates natural logarithm. Vector variant of log1p(x) function for a 128-bit/256-bit vector arguments with float32 values.

Syntax

```
extern __m128 _mm_log1p_ps(__m128 v1);
```

```
extern __m256 _mm256_log1p_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Returns the natural logarithm of vector *v1* elements, defined by:

```
ln (v1 + 1)
```

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_clog_ps, _mm256_clog_ps

Calculates complex natural logarithm. Vector variant of clog(x) function for a 128-bit/256-bit vector argument of _Complex float32 values.

Syntax

```
extern __m128 _mm_clog_ps(__m128 v1);
```

```
extern __m256 _mm256_clog_ps(__m256 v1);
```

Arguments

v1	vector with _Complex float32 values

Description

Calculates the complex natural logarithm of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Intrinsics for Reciprocal Operations (512-bit)

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

`_mm512_recip_ps`, `_mm512_mask_recip_ps`	Computes the approximate reciprocal of packed float32 elements.	**None.**

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result

_mm512_rcp14_pd

```
extern __m512d __cdecl _mm512_rcp14_pd(__m512d a);
```

Computes the approximate reciprocal of packed float64 elements in *a*, and stores the result.

> **NOTE**
> The maximum relative error for this approximation is less than $2^{(-14)}$.

_mm512_mask_rcp14_pd

```
extern __m512d __cdecl _mm512_mask_rcp14_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the approximate reciprocal of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{(-14)}$.

_mm512_maskz_rcp14_pd

```
extern __m512d __cdecl _mm512_maskz_rcp14_pd(__mmask8 k, __m512d a);
```

Computes the approximate reciprocal of packed float64 elements in *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{(-14)}$.

_mm512_rcp14_ps

```
extern __m512 __cdecl _mm512_rcp14_ps(__m512 a);
```

Computes the approximate reciprocal of packed float32 elements in *a*, and stores the result.

NOTE
The maximum relative error for this approximation is less than $2^{(-14)}$.

_mm512_mask_rcp14_ps

```
extern __m512 __cdecl _mm512_mask_rcp14_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the approximate reciprocal of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{(-14)}$.

_mm512_maskz_rcp14_ps

```
extern __m512 __cdecl _mm512_maskz_rcp14_ps(__mmask16 k, __m512 a);
```

Computes the approximate reciprocal of packed float32 elements in *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{(-14)}$.

_mm_rcp14_sd

```
extern __m128d __cdecl _mm_rcp14_sd(__m128d a, __m128d b);
```

Computes the approximate reciprocal of lower float64 element in *b*, stores the result in lower destination element, and copies upper element from *a* to upper destination element.

> **NOTE**
> The maximum relative error for this approximation is less than $2^{(-14)}$.

_mm_mask_rcp14_sd

```
extern __m128d __cdecl _mm_mask_rcp14_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
```

Computes the approximate reciprocal of lower float64 element in *b*, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper element from *a* to upper destination element.

> **NOTE**
> The maximum relative error for this approximation is less than $2^{(-14)}$.

_mm_maskz_rcp14_sd

```
extern __m128d __cdecl _mm_maskz_rcp14_sd(__mmask8 k, __m128d a, __m128d b);
```

Computes the approximate reciprocal of lower float64 element in *b*, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper element from *a* to upper destination element.

> **NOTE**
> The maximum relative error for this approximation is less than $2^{(-14)}$.

_mm_rcp14_ss

```
extern __m128 __cdecl _mm_rcp14_ss(__m128 a, __m128 b);
```

Computes approximate reciprocal of lower float32 element in *b*, stores the result in lower destination element, and copies upper three packed elements from *a* to upper destination elements.

> **NOTE**
> The maximum relative error for this approximation is less than $2^{(-14)}$.

_mm_mask_rcp14_ss

```
extern __m128 __cdecl _mm_mask_rcp14_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);
```

Computes approximate reciprocal of lower float32 element in *b*, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

NOTE
The maximum relative error for this approximation is less than $2^{(-14)}$.

_mm_maskz_rcp14_ss

```
extern __m128 __cdecl _mm_maskz_rcp14_ss(__mmask8 k, __m128 a, __m128 b);
```

Computes approximate reciprocal of lower float32 element in *b*, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

NOTE
The maximum relative error for this approximation is less than $2^{(-14)}$.

_mm512_rcp28_round_pd

```
extern __m512d __cdecl _mm512_rcp28_round_pd(__m512d a);
```

Computes the approximate reciprocal of packed float64 elements in *a*, and stores the result.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_mask_rcp28_round_pd

```
extern __m512d __cdecl _mm512_mask_rcp28_round_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the approximate reciprocal of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_maskz_rcp28_round_pd

```
extern __m512d __cdecl _mm512_maskz_rcp28_round_pd(__mmask8 k, __m512d a);
```

Computes the approximate reciprocal of packed float64 elements in *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_rcp28_pd

```
extern __m512d __cdecl _mm512_rcp28_pd(__m512d a);
```

Computes the approximate reciprocal of packed float64 elements in *a*, and stores the result.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_mask_rcp28_pd

```
extern __m512d __cdecl _mm512_mask_rcp28_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the approximate reciprocal of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_maskz_rcp28_pd

```
extern __m512d __cdecl _mm512_maskz_rcp28_pd(__mmask8 k, __m512d a);
```

Computes the approximate reciprocal of packed float64 elements in *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_rcp28_round_ps

```
extern __m512 __cdecl _mm512_rcp28_round_ps(__m512 a);
```

Computes the approximate reciprocal of packed float32 elements in *a*, and stores the result.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_mask_rcp28_round_ps

```
extern __m512 __cdecl _mm512_mask_rcp28_round_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the approximate reciprocal of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_maskz_rcp28_round_ps

```
extern __m512 __cdecl _mm512_maskz_rcp28_round_ps(__mmask16 k, __m512 a);
```

Computes the approximate reciprocal of packed float32 elements in *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_rcp28_ps

```
extern __m512 __cdecl _mm512_rcp28_ps(__m512 a);
```

Computes the approximate reciprocal of packed float32 elements in *a*, and stores the result.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_mask_rcp28_ps

```
extern __m512 __cdecl _mm512_mask_rcp28_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the approximate reciprocal of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_maskz_rcp28_ps

```
extern __m512 __cdecl _mm512_maskz_rcp28_ps(__mmask16 k, __m512 a);
```

Computes the approximate reciprocal of packed float32 elements in *a*, and stores the result using zeromask *k* (elements are zeroed out when the corresponding mask bit is not set).

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_rcp28_round_sd

```
extern __m128d __cdecl _mm512_rcp28_round_sd(__m128d a, __m128d b);
```

Computes the approximate reciprocal of lower float64 element in *b*, stores the result in lower destination element, and copies upper element from *a* to upper destination element.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_mask_rcp28_round_sd

```
extern __m128d __cdecl _mm512_mask_rcp28_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
```

Computes the approximate reciprocal of lower float64 element in *b*, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper element from *a* to upper destination element.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_maskz_rcp28_round_sd

```
extern __m128d __cdecl _mm512_maskz_rcp28_round_sd(__mmask8 k, __m128d a, __m128d b);
```

Computes the approximate reciprocal of lower float64 element in *b*, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper element from *a* to upper destination element.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_rcp28_round_sd

```
extern __m128d __cdecl _mm512_rcp28_round_sd(__m128d a, __m128d b);
```

Computes the approximate reciprocal of lower float64 element in *b*, stores the result in lower destination element, and copies upper element from *a* to upper destination element.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_mask_rcp28_round_sd

```
extern __m128d __cdecl _mm512_mask_rcp28_round_sd(__m128d src, __mmask8 k, __m128d a, __m128d b);
```

Computes the approximate reciprocal of lower float64 element in *b*, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper element from *a* to upper destination element.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_maskz_rcp28_round_sd

```
extern __m128d __cdecl _mm512_maskz_rcp28_round_sd(__mmask8 k, __m128d a, __m128d b);
```

Computes the approximate reciprocal of lower float64 element in *b*, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper element from *a* to upper destination element.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_rcp28_round_ss

```
extern __m128 __cdecl _mm512_rcp28_round_ss(__m128 a, __m128 b);
```

Computes approximate reciprocal of lower float32 element in *b*, stores the result in lower destination element, and copies upper three packed elements from *a* to upper destination elements.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_mask_rcp28_round_ss

```
extern __m128 __cdecl _mm512_mask_rcp28_round_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);
```

Computes approximate reciprocal of lower float32 element in *b*, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_maskz_rcp28_round_ss

```
extern __m128 __cdecl _mm512_maskz_rcp28_round_ss(__mmask8 k, __m128 a, __m128 b);
```

Computes approximate reciprocal of lower float32 element in *b*, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_rcp28_ss

```
extern __m128 __cdecl _mm512_rcp28_ss(__m128 a, __m128 b);
```

Computes approximate reciprocal of lower float32 element in *b*, stores the result in lower destination element, and copies upper three packed elements from *a* to upper destination elements.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_mask_rcp28_ss

```
extern __m128 __cdecl _mm512_mask_rcp28_ss(__m128 src, __mmask8 k, __m128 a, __m128 b);
```

Computes approximate reciprocal of lower float32 element in *b*, stores the result in lower destination element using writemask *k* (the element is copied from *src* when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_maskz_rcp28_ss

```
extern __m128 __cdecl _mm512_maskz_rcp28_ss(__mmask8 k, __m128 a, __m128 b);
```

Computes approximate reciprocal of lower float32 element in *b*, stores the result in lower destination element using zeromask *k* (the element is zeroed out when mask bit 0 is not set), and copies upper three packed elements from *a* to upper destination elements.

NOTE
The maximum relative error for this approximation is less than $2^{(-28)}$.

_mm512_recip_pd

```
extern __m512d __cdecl _mm512_recip_pd(__m512d a);
```

Computes approximate reciprocal of float64 elements in *a*, and stores the result.

_mm512_mask_recip_pd

```
extern __m512d __cdecl _mm512_mask_recip_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes approximate reciprocal of float64 elements in *a*, and stores the result using writemask *k* (the element is copied from *src* when mask bit 0 is not set).

_mm512_recip_ps

```
extern __m512 __cdecl _mm512_recip_ps(__m512 a);
```

Computes approximate reciprocal of float32 elements in *a*, and stores the result.

_mm512_mask_recip_ps

```
extern __m512 __cdecl _mm512_mask_recip_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes approximate reciprocal of float32 elements in *a*, and stores the result using writemask *k* (the element is copied from *src* when mask bit 0 is not set).

Intrinsics for Root Function Operations (512-bit)

The prototypes for Intel© Advanced Vector Extensions 512 (Intel© AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_sqrt_pd`, `_mm512_mask_sqrt_pd`	Calculates square root of float64 vector elements.	**None.**
`_mm512_sqrt_ps`, `_mm512_mask_sqrt_ps`	Calculates square root of float32 vector elements.	**None.**

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_invsqrt_pd`, `_mm512_mask_invsqrt_pd`	Calculates inverse square root of float64 vector elements.	**None.**
`_mm512_invsqrt_ps`, `_mm512_mask_invsqrt_ps`	Calculates inverse square root of float32 vector elements.	**None.**
`_mm512_hypot_pd`, `_mm512_mask_hypot_pd`	Calculates square root of float64 vector elements.	**None.**
`_mm512_hypot_ps`, `_mm512_mask_hypot_ps`	Calculates square root of float32 vector elements.	**None.**
`_mm512_cbrt_pd`, `_mm512_mask_cbrt_pd`	Calculates cube root of float64 vector elements.	**None.**
`_mm512_cbrt_ps`, `_mm512_mask_cbrt_ps`	Calculates cube root of float32 vector elements.	**None.**

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result

_mm512_sqrt_pd

```
extern __m512d __cdecl _mm512_sqrt_pd(__m512d a);
```

Calculates square root value of float64 vector *a* elements.

_mm512_mask_sqrt_pd

```
extern __m512d __cdecl _mm512_mask_sqrt_pd(__m512d src, __mmask8 k, __m512d a);
```

Calculates square root value of float64 vector *a* elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_sqrt_ps

```
extern __m512 __cdecl _mm512_sqrt_ps(__m512 a);
```

Calculates square root value of float32 vector *a* elements.

_mm512_mask_sqrt_ps

```
extern __m512 __cdecl _mm512_mask_sqrt_ps(__m512 src, __mmask16 k, __m512 a);
```

Calculates square root value of float32 vector *a* elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_invsqrt_pd

```
extern __m512d __cdecl _mm512_invsqrt_pd(__m512d a);
```

Calculates inverse square root value of float64 vector *a* elements.

_mm512_mask_invsqrt_pd

```
extern __m512d __cdecl _mm512_mask_invsqrt_pd(__m512d src, __mmask8 k, __m512d a);
```

Calculates inverse square root value of float64 vector *a* elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_invsqrt_ps

```
extern __m512 __cdecl _mm512_invsqrt_ps(__m512 a);
```

Calculates inverse square root value of float32 vector *a* elements.

_mm512_mask_invsqrt_ps

```
extern __m512 __cdecl _mm512_mask_invsqrt_ps(__m512 src, __mmask16 k, __m512 a);
```

Calculates inverse square root value of float32 vector *a* elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_hypot_pd

```
extern __m512d __cdecl _mm512_hypot_pd(__m512d a, __m512d b);
```

Computes the length of the hypotenuse of a right angled triangle with sides from float64 vector *a* and *b* elements.

_mm512_mask_hypot_pd

```
extern __m512d __cdecl _mm512_mask_hypot_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
```

Computes the length of the hypotenuse of a right angled triangle with sides from float64 vector *a* and *b* elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_hypot_ps

```
extern __m512 __cdecl _mm512_hypot_ps(__m512 a, __m512 b);
```

Computes the length of the hypotenuse of a right angled triangle with sides from float32 vector *a* and *b* elements.

_mm512_mask_hypot_ps

```
extern __m512 __cdecl _mm512_mask_hypot_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);
```

Computes the length of the hypotenuse of a right angled triangle with sides from float32 vector *a* and *b* elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_cbrt_pd

```
extern __m512d __cdecl _mm512_cbrt_pd(__m512d a);
```

Calculates the cube root of float64 vector *a* elements.

_mm512_mask_cbrt_pd

```
extern __m512d __cdecl _mm512_mask_cbrt_pd(__m512d src, __mmask8 k, __m512d a);
```

Calculates the cube root of float64 vector *a* elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_cbrt_ps

```
extern __m512 __cdecl _mm512_cbrt_ps(__m512 a);
```

Calculates the cube root of float32 vector *a* elements.

_mm512_mask_cbrt_ps

```
extern __m512 __cdecl _mm512_mask_cbrt_ps(__m512 src, __mmask16 k, __m512 a);
```

Calculates the cube root of float32 vector *a* elements, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

Intrinsics for Rounding Operations (512-bit)

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_ceil_pd`, `_mm512_mask_ceil_pd`	Rounds float64 vector elements to nearest upper integer.	**None.**
`_mm512_ceil_ps`, `_mm512_mask_ceil_ps`	Rounds float32 vector elements to nearest upper integer.	**None.**
`_mm512_floor_pd`, `_mm512_mask_floor_pd`	Rounds float64 vector elements to nearest lower integer.	**None.**
`_mm512_floor_ps`, `_mm512_mask_floor_ps`	Rounds float32 vector elements to nearest lower integer.	**None.**
`_mm512_nearbyint_pd`, `_mm512_mask_nearbyint_pd`	Rounds float64 vector elements to nearest integer in floating point format.	**None.**
`_mm512_nearbyint_ps`, `_mm512_mask_nearbyint_ps`	Rounds float32 vector elements to nearest integer in floating point format.	**None.**
`_mm512_rint_pd`, `_mm512_mask_rint_pd`	Rounds float64 vector elements to nearest even integer.	**None.**
`_mm512_rint_ps`, `_mm512_mask_rint_ps`	Rounds float32 vector elements to nearest even integer.	**None.**

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_svml_round_pd`, `_mm512_mask_svml_round_pd`	Rounds float64 vector elements to nearest integer.	**None.**
`_mm512_trunc_pd`, `_mm512_mask_trunc_pd`	Rounds float64 vector elements to nearest integer not larger in absolute value.	**None.**
`_mm512_trunc_ps`, `_mm512_mask_trunc_ps`	Rounds float32 vector elements to nearest integer not larger in absolute value.	**None.**

variable	definition
k	writemask used as a selector
a	first source vector element
src	source element to use based on writemask result

_mm512_ceil_pd

```
extern __m512d __cdecl _mm512_ceil_pd(__m512d a);
```

Rounds off the elements of float64 vector *a* to the nearest upper integer value.

_mm512_mask_ceil_pd

```
extern __m512d __cdecl _mm512_mask_ceil_pd(__m512d src, __mmask8 k, __m512d a);
```

Rounds off the elements of float64 vector *a* to the nearest upper integer value, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_ceil_ps

```
extern __m512 __cdecl _mm512_ceil_ps(__m512 a);
```

Rounds off the elements of float32 vector *a* to the nearest upper integer value.

_mm512_mask_ceil_ps

```
extern __m512 __cdecl _mm512_mask_ceil_ps(__m512 src, __mmask16 k, __m512 a);
```

Rounds off the elements of float32 vector *a* to the nearest upper integer value, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_floor_pd

```
extern __m512d __cdecl _mm512_floor_pd(__m512d a);
```

Rounds off the elements of float64 vector *a* to the nearest lower integer value.

_mm512_mask_floor_pd

```
extern __m512d __cdecl _mm512_mask_floor_pd(__m512d src, __mmask8 k, __m512d a);
```

Rounds off the elements of float64 vector *a* to the nearest lower integer value, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_floor_ps

```
extern __m512 __cdecl _mm512_floor_ps(__m512 a);
```

Rounds off the elements of float32 vector *a* to the nearest lower integer value.

_mm512_mask_floor_ps

```
extern __m512 __cdecl _mm512_mask_floor_ps(__m512 src, __mmask16 k, __m512 a);
```

Rounds off the elements of float32 vector *a* to the nearest lower integer value, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_nearbyint_pd

```
extern __m512d __cdecl _mm512_nearbyint_pd(__m512d a);
```

Rounds off the elements of float64 vector *a* to the nearest integer value in floating point format without raising the inexact exception.

_mm512_mask_nearbyint_pd

```
extern __m512d __cdecl _mm512_mask_nearbyint_pd(__m512d src, __mmask8 k, __m512d a);
```

Rounds off the elements of float64 vector *a* to the nearest integer value in floating point format without raising the inexact exception, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_nearbyint_ps

```
extern __m512 __cdecl _mm512_nearbyint_ps(__m512 a);
```

Rounds off the elements of float32 vector *a* to the nearest integer value in floating point format without raising the inexact exception.

_mm512_mask_nearbyint_ps

```
extern __m512 __cdecl _mm512_mask_nearbyint_ps(__m512 src, __mmask16 k, __m512 a);
```

Rounds off the elements of float32 vector *a* to the nearest integer value in floating point format without raising the inexact exception, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_rint_pd

```
extern __m512d __cdecl _mm512_rint_pd(__m512d a);
```

Rounds off the elements of float64 vector *a* to the nearest even integer value.

_mm512_mask_rint_pd

```
extern __m512d __cdecl _mm512_mask_rint_pd(__m512d src, __mmask8 k, __m512d a);
```

Rounds off the elements of float64 vector *a* to the nearest even integer value, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_rint_ps

```
extern __m512 __cdecl _mm512_rint_ps(__m512 a);
```

Rounds off the elements of float32 vector *a* to the nearest even integer value.

_mm512_mask_rint_ps

```
extern __m512 __cdecl _mm512_mask_rint_ps(__m512 src, __mmask16 k, __m512 a);
```

Rounds off the elements of float32 vector *a* to the nearest even integer value, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_svml_round_pd

```
extern __m512d __cdecl _mm512_svml_round_pd(__m512d a);
```

Rounds off the elements of vector *a* to the nearest integer value. This intrinsic rounds the halfway cases away from zero regardless of the current rounding direction, instead of to the nearest even integer like the `_mm512_rint_pd` intrinsic.

_mm512_mask_svml_round_pd

```
extern __m512d __cdecl _mm512_mask_svml_round_pd(__m512d src, __mmask8 k, __m512d a);
```

Rounds off the elements of vector *a* to the nearest integer value. This intrinsic rounds the halfway cases away from zero regardless of the current rounding direction, instead of to the nearest even integer like the `_mm512_rint_pd` intrinsic.

The result is stored using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set)

_mm512_trunc_pd

```
extern __m512d __cdecl _mm512_trunc_pd(__m512d a);
```

Rounds off the elements of float64 vector *a* to the nearest integer value which is not larger in absolute value.

_mm512_mask_trunc_pd

```
extern __m512d __cdecl _mm512_mask_trunc_pd(__m512d src, __mmask8 k, __m512d a);
```

Rounds off the elements of float64 vector *a* to the nearest integer value which is not larger in absolute value, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_trunc_ps

```
extern __m512 __cdecl _mm512_trunc_ps(__m512 a);
```

Rounds off the elements of float32 vector *a* to the nearest integer value which is not larger in absolute value.

_mm512_mask_trunc_ps

```
extern __m512 __cdecl _mm512_mask_trunc_ps(__m512 src, __mmask16 k, __m512 a);
```

Rounds off the elements of float32 vector *a* to the nearest integer value which is not larger in absolute value, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

Intrinsics for Square Root and Cube Root Operations

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sqrt_pd, _mm256_sqrt_pd

Calculates square root value. Vector variant of sqrt(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_sqrt_pd(__m128d v1);
```

```
extern __m256d _mm256_sqrt_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the square root of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sqrt_ps, _mm256_sqrt_ps

Calculates square root value. Vector variant of sqrt(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_sqrt_ps(__m128 v1);
```

```
extern __m256 _mm256_sqrt_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the square root of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_invsqrt_pd, _mm256_invsqrt_pd

Calculates inverse square root value. Vector variant of invsqrt(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_invsqrt_pd(__m128d v1);
```

```
extern __m256d _mm256_invsqrt_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the inverse square root of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_invsqrt_ps, _mm256_invsqrt_ps

Calculates inverse square root value. Vector variant of invsqrt(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_invsqrt_ps(__m128 v1);
```

```
extern __m256 _mm256_invsqrt_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the inverse square root of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cbrt_pd, _mm256_cbrt_pd

Calculates cube root value. Vector variant of cbrt(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_cbrt_pd(__m128d v1);
```

```
extern __m256d _mm256_cbrt_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the cube root of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cbrt_ps, _mm256_cbrt_ps

Calculates cube root value. Vector variant of cbrt(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_cbrt_ps(__m128 v1);
```

```
extern __m256 _mm256_cbrt_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the cube root of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_invcbrt_pd, _mm256_invcbrt_pd

Calculates inverse cube root value. Vector variant of invcbrt(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_invcbrt_pd(__m128d v1);
```

```
extern __m256d _mm256_invcbrt_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the inverse cube root of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_invcbrt_ps, _mm256_invcbrt_ps

Calculates inverse cube root value. Vector variant of invcbrt(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_invcbrt_ps(__m128 v1);
```

```
extern __m256 _mm256_invcbrt_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the inverse cube root of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_csqrt_ps, _mm256_csqrt_ps

Calculates complex square root value. Vector variant of csqrt(x) function for a 128-bit/256-bit vector argument of _Complex float32 values.

Syntax

```
extern __m128 _mm_csqrt_ps(__m128 v1);
```

```
extern __m256 _mm256_csqrt_ps(__m256 v1);
```

Arguments

v1	vector with _Complex float32 values

Description

Calculates the complex square root of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Intrinsics for Trigonometric Operations (512-bit)

The prototypes for Intel® Advanced Vector Extensions 512 (Intel® AVX-512) intrinsics are located in the `zmmintrin.h` header file.
To use these intrinsics, include the `immintrin.h` file as follows:

```
#include <immintrin.h>
```

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_acos_pd`, `_mm512_mask_acos_pd`	Calculates inverse cosine value for float64 vector elements.	**None.**
`_mm512_acos_ps`, `_mm512_mask_acos_ps`	Calculates inverse cosine value for float32 vector elements.	**None.**
`_mm512_acosh_pd`, `_mm512_mask_acosh_pd`	Calculates inverse hyperbolic cosine value for float64 vector elements.	**None.**

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_acosh_ps`, `_mm512_mask_acosh_ps`	Calculates inverse hyperbolic cosine value for float32 vector elements.	**None.**
`_mm512_asin_pd`, `_mm512_mask_asin_pd`	Calculates inverse sine value for float64 vector elements.	**None.**
`_mm512_asin_ps`, `_mm512_mask_asin_ps`	Calculates inverse sine value for float32 vector elements.	**None.**
`_mm512_asinh_pd`, `_mm512_mask_asinh_pd`	Calculates inverse hyperbolic sine value for float64 vector elements.	**None.**
`_mm512_asinh_ps`, `_mm512_mask_asinh_ps`	Calculates inverse hyperbolic sine value for float32 vector elements.	**None.**
`_mm512_atan_pd`, `_mm512_mask_atan_pd`	Calculates inverse tangent value for float64 vector elements.	**None.**
`_mm512_atan_ps`, `_mm512_mask_atan_ps`	Calculates inverse tangent value for float32 vector elements.	**None.**
`_mm512_atan2_pd`, `_mm512_mask_atan2_pd`	Calculates inverse tangent value for float64 elements from multiple vectors.	**None.**
`_mm512_atan2_ps`, `_mm512_mask_atan2_ps`	Calculates inverse tangent value for float32 elements from multiple vectors.	**None.**
`_mm512_atanh_pd`, `_mm512_mask_atanh_pd`	Calculates inverse hyperbolic tangent value for float64 vector elements.	**None.**
`_mm512_atanh_ps`, `_mm512_mask_atanh_ps`	Calculates inverse hyperbolic tangent value for float32 vector elements.	**None.**
`_mm512_cos_pd`, `_mm512_mask_cos_pd`	Calculates cosine value for float64 vector elements.	**None.**
`_mm512_cos_ps`, `_mm512_mask_cos_ps`	Calculates cosine value for float32 vector elements.	**None.**
`_mm512_cosd_pd`, `_mm512_mask_cosd_pd`	Calculates cosine value (in degrees) for float64 vector elements.	**None.**
`_mm512_cosd_ps`, `_mm512_mask_cosd_ps`	Calculates cosine value (in degrees) for float32 vector elements.	**None.**
`_mm512_cosh_pd`, `_mm512_mask_cosh_pd`	Calculates hyperbolic cosine value for float64 vector elements.	**None.**
`_mm512_cosh_ps`, `_mm512_mask_cosh_ps`	Calculates hyperbolic cosine value for float32 vector elements.	**None.**
`_mm512_sin_pd`, `_mm512_mask_sin_pd`	Calculates sine value for float64 vector elements.	**None.**

Intrinsic Name	Operation	Corresponding Intel® AVX-512 Instruction
`_mm512_sin_ps`, `_mm512_mask_sin_ps`	Calculates sine value for float32 vector elements.	**None.**
`_mm512_sincos_pd`, `_mm512_mask_sincos_pd`	Calculates the sine and cosine values for float64 vector elements.	**None.**
`_mm512_sincos_ps`, `_mm512_mask_sincos_ps`	Calculates the sine and cosine values for float32 vector elements.	**None.**
`_mm512_sind_pd`, `_mm512_mask_sind_pd`	Calculates sine value (in degrees) for float64 vector elements.	**None.**
`_mm512_sind_ps`, `_mm512_mask_sind_ps`	Calculates sine value (in degrees) for float32 vector elements.	**None.**
`_mm512_sinh_pd`, `_mm512_mask_sinh_pd`	Calculates hyperbolic sine value for float64 vector elements.	**None.**
`_mm512_sinh_ps`, `_mm512_mask_sinh_ps`	Calculates hyperbolic sine value for float32 vector elements.	**None.**
`_mm512_tan_pd`, `_mm512_mask_tan_pd`	Calculates tangent value for float64 vector elements.	**None.**
`_mm512_tan_ps`, `_mm512_mask_tan_ps`	Calculates tangent value for float32 vector elements.	**None.**
`_mm512_tand_pd`, `_mm512_mask_tand_pd`	Calculates tangent (in degrees) value for float64 vector elements.	**None.**
`_mm512_tand_ps`, `_mm512_mask_tand_ps`	Calculates tangent (in degrees) value for float32 vector elements.	**None.**
`_mm512_tanh_pd`, `_mm512_mask_tanh_pd`	Calculates hyperbolic tangent value for float64 vector elements.	**None.**
`_mm512_tanh_ps`, `_mm512_mask_tanh_ps`	Calculates hyperbolic tangent value for float32 vector elements.	**None.**

variable	definition
k	writemask used as a selector
a	first source vector element
b	second source vector element
src	source element to use based on writemask result

_mm512_acos_pd

```
extern __m512d __cdecl _mm512_acos_pd(__m512d a);
```

Computes the inverse cosine of packed float64 elements in *a*, and stores the result.

_mm512_mask_acos_pd

```
extern __m512d __cdecl _mm512_mask_acos_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the inverse cosine of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_acos_ps

```
extern __m512 __cdecl _mm512_acos_ps(__m512 a);
```

Computes the inverse cosine of packed float32 elements in *a*, and stores the result.

_mm512_mask_acos_ps

```
extern __m512 __cdecl _mm512_mask_acos_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the inverse cosine of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_acosh_pd

```
extern __m512d __cdecl _mm512_acosh_pd(__m512d a);
```

Computes the inverse hyperbolic cosine of packed float64 elements in *a*, and stores the result.

_mm512_mask_acosh_pd

```
extern __m512d __cdecl _mm512_mask_acosh_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the inverse hyperbolic cosine of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_acosh_ps

```
extern __m512 __cdecl _mm512_acosh_ps(__m512 a);
```

Computes the inverse hyperbolic cosine of packed float32 elements in *a*, and stores the result.

_mm512_mask_acosh_ps

```
extern __m512 __cdecl _mm512_mask_acosh_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the inverse hyperbolic cosine of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_asin_pd

```
extern __m512d __cdecl _mm512_asin_pd(__m512d a);
```

Computes the inverse sine of packed float64 elements in *a*, and stores the result.

_mm512_mask_asin_pd

```
extern __m512d __cdecl _mm512_mask_asin_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the inverse sine of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_asin_ps

```
extern __m512 __cdecl _mm512_asin_ps(__m512 a);
```

Computes the inverse sine of packed float32 elements in *a*, and stores the result.

_mm512_mask_asin_ps

```
extern __m512 __cdecl _mm512_mask_asin_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the inverse sine of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_asinh_pd

```
extern __m512d __cdecl _mm512_asinh_pd(__m512d a);
```

Computes the inverse hyperbolic sine of packed float64 elements in *a*, and stores the result.

_mm512_mask_asinh_pd

```
extern __m512d __cdecl _mm512_mask_asinh_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the inverse hyperbolic sine of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_asinh_ps

```
extern __m512 __cdecl _mm512_asinh_ps(__m512 a);
```

Computes the inverse hyperbolic sine of packed float32 elements in *a*, and stores the result.

_mm512_mask_asinh_ps

```
extern __m512 __cdecl _mm512_mask_asinh_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the inverse hyperbolic sine of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_atan2_pd

```
extern __m512d __cdecl _mm512_atan2_pd(__m512d a, __m512d b);
```

Computes the inverse tangent of packed float64 elements in *a* and *b*, and stores the result.

_mm512_mask_atan2_pd

```
extern __m512d __cdecl _mm512_mask_atan2_pd(__m512d src, __mmask8 k, __m512d a, __m512d b);
```

Computes the inverse tangent of packed float64 elements in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_atan2_ps

```
extern __m512 __cdecl _mm512_atan2_ps(__m512 a, __m512 b);
```

Computes the inverse tangent of packed float32 elements in *a* and *b*, and stores the result.

_mm512_mask_atan2_ps

```
extern __m512 __cdecl _mm512_mask_atan2_ps(__m512 src, __mmask16 k, __m512 a, __m512 b);
```

Computes the inverse tangent of packed float32 elements in *a* and *b*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_atan_pd

```
extern __m512d __cdecl _mm512_atan_pd(__m512d a);
```

Computes the inverse tangent of packed float64 elements in *a*, and stores the result.

_mm512_mask_atan_pd

```
extern __m512d __cdecl _mm512_mask_atan_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the inverse tangent of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_atan_ps

```
extern __m512 __cdecl _mm512_atan_ps(__m512 a);
```

Computes the inverse tangent of packed float32 elements in *a*, and stores the result.

_mm512_mask_atan_ps

```
extern __m512 __cdecl _mm512_mask_atan_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the inverse tangent of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_atanh_pd

```
extern __m512d __cdecl _mm512_atanh_pd(__m512d a);
```

Computes the inverse hyperbolic tangent of packed float64 elements in *a*, and stores the result.

_mm512_mask_atanh_pd

```
extern __m512d __cdecl _mm512_mask_atanh_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the inverse hyperbolic tangent of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_atanh_ps

```
extern __m512 __cdecl _mm512_atanh_ps(__m512 a);
```

Computes the inverse hyperbolic tangent of packed float32 elements in *a*, and stores the result.

_mm512_mask_atanh_ps

```
extern __m512 __cdecl _mm512_mask_atanh_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the inverse hyperbolic tangent of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_cos_pd

```
extern __m512d __cdecl _mm512_cos_pd(__m512d a);
```

Computes the cosine of packed float64 elements in *a*, and stores the result.

_mm512_mask_cos_pd

```
extern __m512d __cdecl _mm512_mask_cos_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the cosine of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_cos_ps

```
extern __m512 __cdecl _mm512_cos_ps(__m512 a);
```

Computes the cosine of packed float32 elements in *a*, and stores the result.

_mm512_mask_cos_ps

```
extern __m512 __cdecl _mm512_mask_cos_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the cosine of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_cosd_pd

```
extern __m512d __cdecl _mm512_cosd_pd(__m512d a);
```

Computes the cosine (in degrees) of packed float64 elements in *a*, and stores the result.

_mm512_mask_cosd_pd

```
extern __m512d __cdecl _mm512_mask_cosd_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the cosine (in degrees) of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_cosd_ps

```
extern __m512 __cdecl _mm512_cosd_ps(__m512 a);
```

Computes the cosine (in degrees) of packed float32 elements in *a*, and stores the result.

_mm512_mask_cosd_ps

```
extern __m512 __cdecl _mm512_mask_cosd_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the cosine (in degrees) of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_cosh_pd

```
extern __m512d __cdecl _mm512_cosh_pd(__m512d a);
```

Computes the hyperbolic cosine of packed float64 elements in *a*, and stores the result.

_mm512_mask_cosh_pd

```
extern __m512d __cdecl _mm512_mask_cosh_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the hyperbolic cosine of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_cosh_ps

```
extern __m512 __cdecl _mm512_cosh_ps(__m512 a);
```

Computes the hyperbolic cosine of packed float32 elements in *a*, and stores the result.

_mm512_mask_cosh_ps

```
extern __m512 __cdecl _mm512_mask_cosh_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the hyperbolic cosine (in degrees) of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_sin_pd

```
extern __m512d __cdecl _mm512_sin_pd(__m512d a);
```

Computes the sine of packed float64 elements in *a*, and stores the result.

_mm512_mask_sin_pd

```
extern __m512d __cdecl _mm512_mask_sin_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the sine of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_sin_ps

```
extern __m512 __cdecl _mm512_sin_ps(__m512 a);
```

Computes the sine of packed float32 elements in *a*, and stores the result.

_mm512_mask_sin_ps

```
extern __m512 __cdecl _mm512_mask_sin_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the sine (in degrees) of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_sincos_pd

```
extern __m512d __cdecl _mm512_sincos_pd(__m512d a);
```

Computes the sine and cosine of packed float64 elements in *a*, and stores the result.

_mm512_mask_sincos_pd

```
extern __m512d __cdecl _mm512_mask_sincos_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the sine and cosine of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_sincos_ps

```
extern __m512 __cdecl _mm512_sincos_ps(__m512 a);
```

Computes the sine and cosine of packed float32 elements in *a*, and stores the result.

_mm512_mask_sincos_ps

```
extern __m512 __cdecl _mm512_mask_sincos_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the sineand cosine of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_sind_pd

```
extern __m512d __cdecl _mm512_sind_pd(__m512d a);
```

Computes the sine (in degrees) of packed float64 elements in *a*, and stores the result.

_mm512_mask_sind_pd

```
extern __m512d __cdecl _mm512_mask_sind_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the sine (in degrees) packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_sind_ps

```
extern __m512 __cdecl _mm512_sind_ps(__m512 a);
```

Computes the sine (in degrees) of packed float32 elements in *a*, and stores the result.

_mm512_mask_sind_ps

```
extern __m512 __cdecl _mm512_mask_sind_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the sine (in degrees) of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_sinh_pd

```
extern __m512d __cdecl _mm512_sinh_pd(__m512d a);
```

Computes the hyperbolic sine of packed float64 elements in *a*, and stores the result.

_mm512_mask_sinh_pd

```
extern __m512d __cdecl _mm512_mask_sinh_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the hyperbolic sine of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_sinh_ps

```
extern __m512 __cdecl _mm512_sinh_ps(__m512 a);
```

Computes the hyperbolic sine of packed float32 elements in *a*, and stores the result.

_mm512_mask_sinh_ps

```
extern __m512 __cdecl _mm512_mask_sinh_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the hyperbolic cosine of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_tan_pd

```
extern __m512d __cdecl _mm512_tan_pd(__m512d a);
```

Computes the tangent of packed float64 elements in *a*, and stores the result.

_mm512_mask_tan_pd

```
extern __m512d __cdecl _mm512_mask_tan_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the tangent of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_tan_ps

```
extern __m512 __cdecl _mm512_tan_ps(__m512 a);
```

Computes the tangent of packed float32 elements in *a*, and stores the result.

_mm512_mask_tan_ps

```
extern __m512 __cdecl _mm512_mask_tan_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the tangent of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_tand_pd

```
extern __m512d __cdecl _mm512_tand_pd(__m512d a);
```

Computes the tangent (in degrees) of packed float64 elements in *a*, and stores the result.

_mm512_mask_tand_pd

```
extern __m512d __cdecl _mm512_mask_tand_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes tangent (in degrees) of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_tand_ps

```
extern __m512 __cdecl _mm512_tand_ps(__m512 a);
```

Computes the tangent (in degrees) of packed float32 elements in *a*, and stores the result.

_mm512_mask_tand_ps

```
extern __m512 __cdecl _mm512_mask_tand_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the tangent (in degrees) of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_tanh_pd

```
extern __m512d __cdecl _mm512_tanh_pd(__m512d a);
```

Computes the hyperbolic tangent of packed float64 elements in *a*, and stores the result.

_mm512_mask_tanh_pd

```
extern __m512d __cdecl _mm512_mask_tanh_pd(__m512d src, __mmask8 k, __m512d a);
```

Computes the hyperbolic tangent of packed float64 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

_mm512_tanh_ps

```
extern __m512 __cdecl _mm512_tanh_ps(__m512 a);
```

Computes the hyperbolic tangent of packed float32 elements in *a*, and stores the result.

_mm512_mask_tanh_ps

```
extern __m512 __cdecl _mm512_mask_tanh_ps(__m512 src, __mmask16 k, __m512 a);
```

Computes the hyperbolic tangent of packed float32 elements in *a*, and stores the result using writemask *k* (elements are copied from *src* when the corresponding mask bit is not set).

Intrinsics for Trigonometric Operations

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

For information about 512-bit trigonometric intrinsics for SVML, see Intrinsics for Trigonometric Operations (512-bit).

_mm_acos_pd, _mm256_acos_pd

Calculates inverse cosine value. Vector variant of acos(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_acos_pd(__m128d v1);
```

```
extern __m256d _mm256_acos_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the arc cosine of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_acos_ps, _mm256_acos_ps

Calculates inverse cosine value. Vector variant of acos(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_acos_ps(__m128 v1);
```

```
extern __m256 _mm256_acos_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the arc cosine of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_acosh_pd, _mm256_acosh_pd

Calculates the inverse hyperbolic cosine value. Vector variant of acosh(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_acosh_pd(__m128d v1);
```

```
extern __m256d _mm256_acosh_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the inverse hyperbolic cosine of vector *v1* values.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_acosh_ps, _mm256_acosh_ps

Calculates the inverse hyperbolic cosine value. Vector variant of acosh(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_acosh_ps(__m128 v1);
```

```
extern __m256 _mm256_acosh_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the inverse hyperbolic cosine of vector *v1* values.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_asin_pd, _mm256_asin_pd

Calculates inverse sine value. Vector variant of asin(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_asin_pd(__m128d v1);
```

```
extern __m256d _mm256_asin_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the arc sine of vector *v1* values.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_asin_ps, _mm256_asin_ps

Calculates inverse sine value. Vector variant of asin(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_asin_ps(__m128 v1);
```

```
extern __m256 _mm256_asin_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the arc sine of vector *v1* values.

Returns

128-bit/256-bit vector with result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_asinh_pd, _mm256_asinh_pd

Calculates the inverse hyperbolic sine value. Vector variant of asinh(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_asinh_pd(__m128d v1);
```

```
extern __m256d _mm256_asinh_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the inverse hyperbolic sine of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_asinh_ps, _mm256_asinh_ps

Calculates the inverse hyperbolic sine value. Vector variant of asinh(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_asinh_ps(__m128 v1);
```

```
extern __m256 _mm256_asinh_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the inverse hyperbolic sine of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_atan_pd, _mm256_atan_pd

Calculates inverse tangent value. Vector variant of atan(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_atan_pd(__m128d v1);
```

```
extern __m256d _mm256_atan_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the arc tangent of vector *v1* elements. In effect, the tangent of each resulting element value is the value of the corresponding *v1* vector element.

Returns

128-bit/256-bit vector with result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_atan_ps, _mm256_atan_ps

Calculates inverse tangent value. Vector variant of atan(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_atan_ps(__m128 v1);
```

```
extern __m256 _mm256_atan_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the arc tangent of vector *v1* elements. In effect, the tangent of each resulting element value is the value of the corresponding *v1* vector element.

Returns

128-bit/256-bit vector with result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_atan2_pd, _mm256_atan2_pd

Calculates the inverse tangent of float64 variables x and y. Vector variant of atan2(x, y) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_atan2_pd(__m128d v1, __m128 v2);
```

```
extern __m256d _mm256_atan2_pd(__m256d v1, __m256 v2);
```

Arguments

v1	vector with float64 values
v2	vector with float64 values

Description

Calculates the arc tangent of corresponding float64 elements of vectors *v1* and *v2*. The following is an illustration of the atan2 operation:

```
Res[0]  = atan2(v1[0], v2[0])
Res[1]  = atan2(v1[1], v2[1])
Res[2]  = atan2(v1[2], v2[2])
Res[15] = atan2(v1[15], v2[15])
...
```

NOTE
This calculation is similar to calculating the arc tangent of `y / x`, except that the signs of both arguments are used to determine the quadrant of the result.

Returns

Result of the bitwise operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_atan2_ps, _mm256_atan2_ps

Calculates the inverse tangent of float32 variables x and y. Vector variant of atan2(x, y) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_atan2_ps(__m128 v1, __m128 v2);
```

```
extern __m256 _mm256_atan2_ps(__m256 v1, __m256 v2);
```

Arguments

v1	vector with float32 values

v2 vector with float32 values

Description

Calculates the arc tangent of corresponding float32 elements of vectors *v1* and *v2*. The following is an illustration of the atan2 operation:

```
Res[0]  = atan2(v1[0], v2[0])
Res[1]  = atan2(v1[1], v2[1])
Res[2]  = atan2(v1[2], v2[2])
Res[15] = atan2(v1[15], v2[15])
...
```

NOTE
This calculation is similar to calculating the arc tangent of `y / x`, except that the signs of both arguments are used to determine the quadrant of the result.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_atanh_pd, _mm256_atanh_pd

Calculates inverse hyperbolic tangent value. Vector variant of atanh(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_atanh_pd(__m128d v1);
```

```
extern __m256d _mm256_atanh_pd(__m256d v1);
```

Arguments

v1 vector with float64 values

Description

Calculates the inverse hyperbolic tangent of vector *v1* elements. In effect, the hyperbolic tangent of each resulting element value is the value of the corresponding *v1* vector element.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_atanh_ps, _mm256_atanh_ps

Calculates inverse hyperbolic tangent value. Vector variant of atanh(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_atanh_ps(__m128 v1, __m128 v2);
```

```
extern __m256 _mm256_atanh_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the inverse hyperbolic tangent of vector *v1* elements. In effect, the hyperbolic tangent of each resulting element value is the value of the corresponding *v1* vector element.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cos_pd, _mm256_cos_pd

Calculates cosine value. Vector variant of cos(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_cos_pd(__m128d v1);
```

```
extern __m256d _mm256_cos_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the cosine of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cos_ps, _mm256_cos_ps

Calculates cosine value. Vector variant of cos(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_cos_ps(__m128 v1);
```

```
extern __m256 _mm256_cos_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the cosine of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cosd_pd, _mm256_cosd_pd

Calculates cosine value. Vector variant of cosd(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_cosd_pd(__m128d v1);
```

```
extern __m256d _mm256_cosd_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the cosine of vector *v1* elements, measured in degrees.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cosd_ps, _mm256_cosd_ps

Calculates cosine value. Vector variant of cosd(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_cosd_ps(__m128 v1);
```

```
extern __m256 _mm256_cosd_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the cosine of vector *v1* elements, measured in degrees.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cosh_pd, _mm256_cosh_pd

Calculates the hyperbolic cosine value. Vector variant of cosh(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_cosh_pd(__m128d v1, __m128d v2);
```

```
extern __m256d _mm256_cosh_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the hyperbolic cosine of vector *v1* elements, which is defined mathematically as:

```
(exp(x) + exp(-x)) / 2
```

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_cosh_ps, _mm256_cosh_ps

Calculates the hyperbolic cosine value. Vector variant of cosh(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_cosh_ps(__m128 v1);
```

```
extern __m256 _mm256_cosh_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the hyperbolic cosine of vector *v1* elements, which is defined mathematically as:

```
(exp(x) + exp(-x)) / 2
```

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sin_pd, _mm256_sin_pd

Calculates sine value. Vector variant of sin(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_sin_pd(__m128d v1);
```

```
extern __m256d _mm256_sin_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the sine of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sin_ps, _mm256_sin_ps

Calculates sine value. Vector variant of sin(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_sin_ps(__m128 v1);
```

```
extern __m256 _mm256_sin_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the sine of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sind_pd, _mm256_sind_pd

Calculates sine value. Vector variant of sind(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_sind_pd(__m128d v1);
```

```
extern __m256d _mm256_sind_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the sine of vector *v1* elements, measured in degrees.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sind_ps, _mm256_sind_ps

Calculates sine value. Vector variant of sind(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_sind_ps(__m128 v1);
```

```
extern __m256 _mm256_sind_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the sine of vector *v1* elements, measured in degrees.

Returns

128-bit/256-bit vector with the result of the operation.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sinh_pd, _mm256_sinh_pd

Calculates the hyperbolic sine value. Vector variant of sinh(x) function for a 128-bit/256-bit vector argument of float64 values.

Syntax

```
extern __m128d _mm_sinh_pd(__m128d v1);
```

```
extern __m256d _mm256_sinh_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the hyperbolic sine of vector v1 elements, which is defined mathematically as:

$$(\exp^{(x)} - \exp^{(-x)}) / 2$$

.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sinh_ps, _mm256_sinh_ps

Calculates the hyperbolic sine value. Vector variant of sinh(x) function for a 128-bit/256-bit vector argument of float32 values.

Syntax

```
extern __m128 _mm_sinh_ps(__m128 v1);
```

```
extern __m256 _mm256_sinh_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the hyperbolic sine of vector v1 elements, which is defined mathematically as:

$$(\exp^{(x)} - \exp^{(-x)}) / 2$$

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_tan_pd, _mm256_tan_pd

Calculates tangent value. Vector variant of tan(x) function for a 128-bit/256-bit vector arguments with float64 values.

Syntax

```
extern __m128d _mm_tan_pd(__m128d v1);
```

```
extern __m256d _mm256_tan_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the tangent of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_tan_ps, _mm256_tan_ps

Calculates tangent value. Vector variant of tan(x) function for a 128-bit/256-bit vector arguments with float32 values.

Syntax

```
extern __m128 _mm_tan_ps(__m128 v1);
```

```
extern __m256 _mm256_tan_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the tangent of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_tand_pd, _mm256_tand_pd

Calculates tangent value. Vector variant of tand(x) function for a 128-bit/256-bit vector arguments with float64 values.

Syntax

```
extern __m128d _mm_tand_pd(__m128d v1);
```

```
extern __m256d _mm256_tand_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the tangent of vector *v1* elements, measured in degrees.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_tand_ps, _mm256_tand_ps

Calculates the tangent value. Vector variant of tand(x) function for a 128-bit/256-bit vector arguments with float32 values.

Syntax

```
extern __m128 _mm_tand_ps(__m128 v1);
extern __m256 _mm256_tand_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the tangent of vector *v1* elements, measured in degrees.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_tanh_pd, _mm256_tanh_pd

Calculates hyperbolic tangent value. Vector variant of tanh(x) function for a 128-bit/256-bit vector arguments with float64 values.

Syntax

```
extern __m128d _mm_tanh_pd(__m128d v1);
extern __m256d _mm256_tanh_pd(__m256d v1);
```

Arguments

v1	vector with float64 values

Description

Calculates the hyperbolic tangent of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_tanh_ps, _mm256_tanh_ps

Calculates hyperbolic tangent value. Vector variant of tanh(x) function for a 128-bit/256-bit vector arguments with float32 values.

Syntax

```
extern __m128 _mm_tanh_ps(__m128 v1);
```

```
extern __m256 _mm256_tanh_ps(__m256 v1);
```

Arguments

v1	vector with float32 values

Description

Calculates the hyperbolic tangent of vector *v1* elements.

Returns

128-bit/256-bit vector with the result of the operation.

NOTE
Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sincos_pd, _mm256_sincos_pd

Calculates the sine and cosine values. Vector variant of sincos(x, &sin_x, &cos_x) function for a 128-bit/256-bit vector with float64 values.

Syntax

```
extern __m128d _mm_sincos_pd(__m128d *p_cos, __m128d v1);
```

```
extern __m256d _mm256_sincos_pd(__m256d *p_cos, __m256d v1);
```

Arguments

**p_cos*	points to vector of cosine results (pointer must be aligned on 16 bytes, or declared as `__m128d*` instead)
v1	vector with float64 values

Description

Calculates sine and cosine values of vector *v1* elements.

The cosine and sine values cannot be returned in the result vector. Therefore, the intrinsic stores the cosine values at a location pointed to by*p_cos*, and returns only the sine values in the 128-bit result vector.

Returns

128-bit/256-bit vector with the sine results.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

_mm_sincos_ps, _mm256_sincos_ps

Calculates the sine and cosine values. Vector variant of sincos(x, &sin_x, &cos_x) function for a 128-bit/256-bit vector with float32 values.

Syntax

```
extern __m128 _mm_sincos_ps(__m128 *p_cos, __m128 v1);
```

```
extern __m256 _mm256_sincos_ps(__m256 *p_cos, __m256 v1);
```

Arguments

**p_cos*	points to vector of cosine results (pointer must be aligned on 16 bytes, or declared as `__m128*` instead)
v2	vector with float32 values

Description

Calculates sine and cosine values of vector *v1* elements.

The cosine and sine values cannot be returned in the result vector. Therefore, the intrinsic stores the cosine values at a location pointed to by*p_cos*, and returns only the sine values in the 128-bit result vector.

Returns

128-bit/256-bit vector with the sine results.

> **NOTE**
> Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Libraries

The Intel® C++ Compiler lets you use all the standard run-time libraries that are part of Microsoft* Visual C++*. The options described in this section can help you determine which libraries your application uses.

To create libraries, use the `lib.exe` tool or `xilib.exe` tool.

Create Libraries

Libraries are simply an indexed collection of object files that are included as needed in a linked program. Combining object files into a library makes it easy to distribute your code without disclosing the source. It also reduces the number of command-line entries needed to compile your project.

Static Libraries

Executables generated using static libraries are no different than executables generated from individual source or object files. Static libraries are not required at runtime, so you do not need to include them when you distribute your executable. At compile time, linking to a static library is generally faster than linking to individual source files.

These steps show how to build a static library on Linux using the `icpc` driver . See Invoke the Compiler for information about all available drivers.

1. Use the `c` option to generate object files from the source files:

```
icpc -c my_source1.cpp my_source2.cpp my_source3.cpp
```

2. Use the GNU* tool `ar` to create the library file from the object files:

```
ar rc my_lib.a my_source1.o my_source2.o my_source3.o
```

3. Compile and link your project with your new library:

```
icpc main.cpp my_lib.a
```

If your library file and source files are in different directories, use the `L`*`dir`* option to indicate where your library is located:

```
icpc -L/cpp/libs main.cpp my_lib.a
```

To build a static library on macOS:

1. Use the following command to generate object files and create the library file:

```
icpc -fpic -o mylib.a -staticlib my_source1.cpp my_source2.cpp my_source3.cpp
```

2. Compile and link your project with your new library:

```
icpc main.cpp my_lib.a
```

If your library file and source files are in different directories, use the `L`*`dir`**dir* option to indicate where your library is located:

```
icpc -L/cpp/libs main.cpp my_lib.a
```

If you are using Interprocedural Optimization, see the topic Create a Library from IPO Objects, which discusses using `xiar`.

Shared Libraries

Shared libraries, also referred to as dynamic libraries or Dynamic Shared Objects (DSO), are linked differently than static libraries. At compile time, the linker insures that all the necessary symbols are either linked into the executable, or can be linked at runtime from the shared library. Executables compiled from shared libraries are smaller, but the shared libraries must be included with the executable to function correctly. When multiple programs use the same shared library, only one copy of the library is required in memory.

Linux

These steps show how to build a shared library on Linux using the `icpc` driver . See Invoke the Compiler for information about all available drivers.

1. Use options `fPIC` and `c` to generate object files from the source files:

```
icpc -fPIC -c my_source1.cpp my_source2.cpp my_source3.cpp
```

2. Use the `shared` option to create the library file from the object files:

```
icpc -shared -o my_lib.so my_source1.o my_source2.o my_source3.o
```

3. Compile and link your project with your new library:

```
icpc main.cpp my_lib.so
```

macOS

These steps show how to build a shared library on macOS using the `icpc` driver

1. Use the following command to generate object files and create the library file:

```
icpc -fPIC -o my_lib.so -dynamiclib my_source1.cpp my_source2.cpp my_source3.cpp
```

2. Compile and link your project with your new library:

```
icpc main.cpp my_lib.dylib
```

Windows

Use the following options to create libraries on Windows:

Option	Description
`/LD`, `/LDd`	Produces a DLL. `d` indicates debug version.
`/MD`, `/MDd`	Compiles and links with the dynamic, multi-thread C run time library. `d` indicates debug version.
`/MT`, `/MTd`	Compiles and links with the static, multi-thread C run time library. `d` indicates debug version.
`/Zl`	Disables embedding default libraries in object files.

Use Intel Shared Libraries

This topic applies to Linux and macOS.

By default, the Intel® C++ Compiler Classic links Intel® C++ libraries dynamically. The GNU/Linux/macOS system libraries are also linked dynamically.

Options for Shared Libraries (Linux)

Option	Description
`-shared-intel`	Use the `shared-intel` option to link Intel®-provided libraries dynamically. This has the advantage of reducing the size of the application binary, but it also requires the libraries to be on the application's target system.
`-shared`	The `shared` option instructs the compiler to build a Dynamic Shared Object (DSO) instead of an executable. For more details, refer to the `ld` man page documentation.
`-fpic`	Use the `fpic` option when building shared libraries. It is required for the compilation of each object file included in the shared library.

Options for Shared Libraries (macOS)

Option	Description
`-dynamiclib`	Use the `dynamiclib` option to invoke the `libtool` command to generate dynamic libraries.
`-fpic`	Use the `fpic` option when building shared libraries. It is required for the compilation of each object file included in the shared library.

Using Shared Libraries on macOS

This topic only applies to macOS.

On macOS, it is possible to store path information in shared libraries to perform library searches. The compiler installation changes the path to the installation directory, but you will need to modify these paths if you move the libraries elsewhere. For example, you may want to bundle redistributable Intel® libraries with your application. This eliminates the dependency on libraries found on `DYLD_LIBRARY_PATH`.

If your compilations do not use `DYLD_LIBRARY_PATH` to find libraries, and you distribute executables that depend on shared libraries, then you will need to modify the Intel shared libraries (`../lib/*.dylib`) using the `install_name_tool` to set the correct path to the shared libraries. This also permits the end-user to launch the application by double-clicking on the executable. The command below will modify each library with the correct absolute path information:

```
for i in *.dylib
do
    echo -change $i `pwd`/$i
    done > changes
for i in *.dylib
do
    install_name_tool `cat changes` $i
done
```

You can also use the `install_name_tool` to set `@executable_path` to change path information for the libraries bundled in your application by changing the path appropriately.

Be sure to recompile your sources after modifying the libraries.

Manage Libraries

Manage Libraries on Linux and macOS

During compilation, the compiler reads the `LIBRARY_PATH` environment variable for static libraries it needs to link when building the executable. At runtime, the executable will link against dynamic libraries referenced in the `LD_LIBRARY_PATH` environment variable. Add the location of your static libraries to the `LIBRARY_PATH` environment variable so that they are available for linking during compilation.

For example, to compile `file.cpp` and link it with the library `lib.a`, located in the `/libs` directory:

1. Add the directory `/libs` to `LIBRARY_PATH` from the command line with the export command:

```
export LIBRARY_PATH=/libs:$LIBRARY_PATH
```

   Alternately, add the directory to `LIBRARY_PATH` by addiing the export command to your startup file.
2. Compile `file.cpp` and link it with `lib.a`:

```
icc file.cpp lib.a
```

To link your library during compilation without modifying the `LIBRARY_PATH` environment variable use the `-L` option. For example:

```
icc file.cpp -L /libs lib.a
```

During compilation, the compiler passes object files to the linker in the following order:

1. Object files, from files specified on the command line, in the order they are specified (left to right)
2. Objects or libraries specified in default configuration files
3. Default Intel and system libraries

For example, the command

```
icc lib1.a file.cpp lib2.a
```

would have the following link order:

1. `lib1.a`
2. `file.o`
3. `lib2.a`
4. Objects or libraries specified in default configuration files
5. Default Inel and system libraries

Manage Libraries on Windows

The `LIB` environment variable contains a semicolon-separated list of directories in which the Microsoft linker will search for library (`.lib`) files. The compiler does not specify library names to the linker but includes directives in the object file to specify the libraries to be linked with each object.

For more information on adding library names to the response file and the configuration file, see Using Response Files and Using Configuration Files.

To specify a library name on the command line, you must first add the library's path to the `LIB` environment variable. Then you can specify the library name on the command line. For example, to compile `file.cpp` and link it with the library `mylib.lib` enter the command:

```
icc file.cpp mylib.lib
```

Other Considerations

The Intel Compiler Math Libraries contain performance-optimized implementations for various Intel platforms. By default, the best implementation for the underlying hardware is selected at runtime. The library dispatch of multi-threaded code may lead to apparent data races, which may be detected by certain software analysis tools. However, as long as the threads are running on cores with the same CPUID, these data races are harmless and are not a cause for concern.

Redistribute Libraries When Deploying Applications

When you deploy your application to systems that do not have a compiler installed, you need to redistribute certain Intel® libraries where your application is linked. You can do so in one of the following ways:

- Statically link your application.

  An application built with statically-linked libraries eliminates the need to distribute runtime libraries with the application executable. By linking the application to the static libraries, you are not dependent on the Intel® Fortran or Intel® C/C++ dynamic shared libraries.
- Dynamically link your application.

  If you must build your application with dynamically linked (or shared) compiler libraries, you should address the following concerns:

  - You must build your application with shared or dynamic libraries that are redistributable.
  - Pay careful attention to the directory where the redistributables are installed and how the OS finds them.
  - You should determine which shared or dynamic libraries your application needs.

The information here is only introductory. The redistributable library installation packages are available at the following locations:

- Intel® oneAPI versions
- Older Intel® Parallel Studio XE versions

Resolve References to Shared Libraries

If you are relying on shared libraries distributed with Intel® oneAPI tools, you must make sure that your users have these shared libraries on their systems.

If you are building an application that will be deployed to your user community and you are relying on shared libraries (`.so` shared objects on Linux, `.dll` dynamic libraries on Windows, and `.dylib` dynamic libraries on macOS) distributed with Intel® oneAPI tools, you must make sure that your users have these shared libraries on their systems. To determine what shared libraries you depend on, use one of the following commands for each of your programs and components:

Linux

```
ldconfig
```

macOS

```
otool -L
```

Windows

```
dumpbin /DEPENDENTS programOrComponentName
```

Once you have done this, you must choose how your users will receive these libraries.

Shared Library Deployment

Once you have built, run, and debugged your application, you must deploy it to your users. That deployment includes any shared libraries, including libraries that are components of the Intel® oneAPI toolkits.

Deployment Models

You have two options for deploying the shared libraries from the Intel oneAPI toolkit that your application depends on:

Private Model	Copy the shared libraries from the Intel oneAPI toolkit into your application environment, and then package and deploy them with your application. Review the license and third-party files associated with the Intel oneAPI toolkits and/or components you have installed to determine the files that you can redistribute. The advantage to this model is that you have control over your library and version choice, so you only package and deploy the libraries that you have tested. The disadvantage is that the end users may see multiple libraries installed on their system, if multiple installed applications all use the private model. You are also responsible for updating these libraries whenever updates are required.
Public Model	You direct your users to runtime packages provided by Intel. Your users install these packages on their system when they install your application. The runtime packages install onto a fixed location, so all applications built with Intel oneAPI tools can be used. The advantage is that one copy of each library is shared by all applications, which results in improved performance. You can rely on updates to the runtime packages to resolve issues with libraries independently from when you update your application. The disadvantage is that the footprint of the runtime package is larger than a package from the private model. Another disadvantage is that your tested versions of the runtime libraries may not be the same as your end user's versions.

Select the model that best fits your environment, your needs, and the needs of your users.

NOTE Intel ensures that newer compiler-support libraries work with older versions of generated compiler objects, but newer versioned objects require newer versioned compiler-support libraries. If an incompatibility is introduced that causes newer compiler-support libraries not to work with older compilers, you will have sufficient warning and the library will be versioned so that deployed applications continue to work.

Additional Steps

Under either model, you must manually configure certain environment variables that are normally handled by the `setvars`/`vars` scripts or module files.

For example, with the Intel® MPI Library, you must set the following environment variables during installation:

Linux

```
I_MPI_ROOT=installPath FI_PROVIDER_PATH=installPath/intel64/libfabric:/usr/lib64/libfabric
```

Windows

```
I_MPI_ROOT=installPath
```

Compatibility in the Minor Releases of the Intel oneAPI Products

For Intel oneAPI products, each minor version of the product is compatible with the other minor version from the same release (for example, 2021). When there are breaking changes in API or ABI, the major version is increased. For example, if you tested your application with an Intel oneAPI product with a 2021.1 version, it will work with all 2021.x versions. It is not guaranteed that it will work with 2022.x or 19.x versions.

Intel's Memory Allocator Library

Intel's `libqkmalloc` library for fast memory allocation provides a C-level interface for memory allocation that is optimized for performance.

You can link the `libqkmalloc` library as a shared library only on Linux* platforms for Intel® 64 architecture. This library provides optimized implementation of standard allocation routines `malloc`, `calloc`, `realloc`, and `free`, and is C99 standard compliant.

> **NOTE** This library is limited to work only on Intel® processors and will redirect to standard C routines at runtime if used on non-Intel® processors.

Use Intel's Custom Memory Allocator Library

You can use the libqkmalloc library by linking directly to it or by using the `LD_PRELOAD` environment variable.

To ensure the application will override the standard library allocation routines with `libqkmalloc`, set the environment variable LD_PRELOAD in the command line before the application execution. This environment variable allows you to set the path of the library that will be loaded before any other library (including the C runtime library), and the application will use symbols from this specified library instead of the symbols from the standard library.

Restrictions

This library does not support threaded code such as OpenMP* and is not thread-safe. It should not be used simultaneously from multiple threads. For the best results this library should be used with large throughput workloads.

SIMD Data Layout Templates

SIMD Data Layout Templates (SDLT) is a C++11 template library providing containers that represent arrays of "Plain Old Data" objects (a struct whose data members do not have any pointers/references and no virtual functions) using layouts that enable generation of efficient SIMD (single instruction multiple data) vector code. SDLT uses standard ISO C++11 code. It does not require a special language or compiler to be functional, but takes advantage of performance features (such as OpenMP* SIMD extensions and `pragma ivdep`) that may not be available to all compilers. It is designed to promote scalable SIMD vector programming. To use the library, specify SIMD loops and data layouts using explicit vector programming model and SDLT containers, and let the compiler generate efficient SIMD code in an efficient manner.

Many of the library interfaces employ generic programming, in which interfaces are defined by requirements on types and not specific types. The C++ Standard Template Library (STL) is an example of generic programming. Generic programming enables SDLT to be flexible yet efficient. The generic interfaces enable you to customize components to your specific needs.

The net result is that SDLT enables you to specify a preferred SIMD data layout far more conveniently than re-structuring your code completely with a new data structure for effective vectorization, and at the same time can improve performance.

Motivation

C++ programs often represent an algorithm in terms of high level objects. For many algorithms there is a set of data that the algorithm will need to process. It is common for the data set to be represented as array of "plain old data" objects. It is also common for developers to represent that array with a container from the C ++ Standard Template Library, like std::vector. For example:

```
struct Point3s
{
    float x;
    float y;
    float z;
       // helper methods
};

std::vector<Point3s> inputDataSet(count);
std::vector<Point3s> outputDataSet(count);

for(int i=0; i < count; ++i) {
  Point3s inputElement = inputDataSet[i];
  Point3s result = // transformation of inputElement that is independent of other iterations
                   // can keep algorithm high level using object helper methods
  outputDataSet[i] = result;
}
```

When possible a compiler may attempt to vectorize the loop above, however the overhead of loading the "Array of Structures" data set into vector registers may overcome any performance gain of vectorizing. Programs exhibiting the scenario above could be good candidates to use a SDLT container with a SIMD-friendly internal memory layout. SDLT containers provide *accessor* objects to import and export Primitives between the underlying memory layout and the objects original representation. For example:

```
SDLT_PRIMITIVE(Point3s, x, y, z)

sdlt::soa1d_container<Point3s> inputDataSet(count);
sdlt::soa1d_container<Point3s> outputDataSet(count);

auto inputData = inputDataSet.const_access();
auto outputData = outputDataSet.access();

#pragma forceinline recursive
#pragma omp simd
for(int i=0; i < count; ++i) {
  Point3s inputElement = inputData[i];
  Point3s result = // transformation of inputElement that is independent of other iterations
                   // can keep algorithm high level using object helper methods
  outputData[i] = result;
}
```

When a local variable inside the loop is imported from or exported to using that loop's index, the compiler's vectorizor can now access the underlying SIMD friendly data format and when possible perform unit stride loads. If the compiler can prove nothing outside the loop can access the loop's local object, then it can optimize its private representation of the loop object be "Structure of Arrays" (SOA). In our example, the container's underlying memory layout is also SOA and unit stride loads can be generated. The Container also allocates aligned memory and its accessor objects provide the compiler with the correct alignment information for it to optimize code generation accordingly.

Version Information

This documentation is for SDLT version 2, which extends version 1 by introducing support for n-dimensional containers.

Backwards Compatibility

Public interfaces of version 2 are fully backward compatible with interfaces of version 1.

The backwards compatibility includes:

- Existing source code compatibility.
  - Any source code using the SDLT v1 public API (non-internal interfaces) can be recompiled against SDLT v2 headers with no changes.
- Binary compatibility.
  - Because SDLT v2 API's exist in a new name space, sdlt::v2, all ABI linkage should not collide with any existing SDLT v1 ABI's that exist only in sdlt namespace.
  - A binary, dynamically-linked library that uses SDLT v1 internally, can be linked into a program using SDLT v2, and vice versa.
- Passing SDLT containers or accessors as part of a libraries public API (ABI). When SDLT is used as part of an ABI, that library and the calling code must use the same version of SDLT. They cannot be mixed or matched.

This compatibility doesn't cover internal implementation. Internal implementation for SDLT v1 was updated and unified with parts introduced in v2, so for codes dependent on internal interfaces backwards compatibility is not guaranteed.

Deprecated

The interfaces below are deprecated; use the replacements provided in the table.

Deprecated Interface	Deprecated in Version	Replaced By
`sdlt::fixed_offset<>`	v2	`sdlt::fixed<>`
`sdlt::aligned_offset<>`	v2	`sdlt::aligned<>`

Usage Guidelines: Function Calls and Containers

Function Calls

Function calls are a commonly used programming construct. Follow these simple guidelines when using SDLT containers:

- If an SDLT Primitive is passed to a function by value, by pointer, or by reference, be sure to inline them
- Any Non-inlined functions should be SIMD enabled (for example, marke them with #pragma omp declare simd).

If a loop variable is passed to a non-inlined function, the current C++ Application Binary Interface (ABI) requires the memory layout match object's original which could cause additional data transformations or inhibit vectorization. For that reason, the SDLT approach works best when all the methods or functions called are inlined or use `#pragma omp declare simd`. Marking a function "inline" explicitly or implicitly is only a hint. Compilers have several limits and heuristics that could cause a function to not be inlined. To avoid this issue, we recommend utilizing the `#pragma forceinline recursive` which instructs the compiler to ignore its limits and heuristics: causing all functions in the following code block that could be inlined to actually be inlined together with any functions called, and functions they call, and so on. Please also note that this can cause the loop body and/or the function body to become too big to optimize. Under such circumstances, carefully examine and restructure the function call boundaries and consider applying non-inlined, SIMD-enabled function calls.

1-Dimensional Containers Overview

What if that std::vector<typename> could store data SIMD-friendly format internally while exposing an AOS view to the programmer?

The 1-dimensional containers in SDLT aim to achieve that goal. They can abstract the in-memory data layout of an array of objects to:

1. AOS (Array of Structures)
2. SOA (Structure of Arrays) which is SIMD friendly

Import/Export Only

As the memory layout is abstracted and may not match the original structure's layout, containers cannot provide memory references to the underlying data. Only import or export of the object to and from a particular element in the container. In use, an algorithm might require some minor code changes to follow import/export paradigm, however algorithm itself should read/flow the same.

The 1D containers in SDLT are dynamically resizable with an interface similar to std::vector<T>. To avoid accidental misuse of copying containers into C++11 lambda functions we chose to delete the container's copy constructor and instead provide explicit "clone" method instead.

Containers provide SDLT concepts of an accessor and const_accessor for use with SIMD loops, interfaces for `std::vector` compatibility are intended for ease of integration, not high performance.

Just like `std::vector`, the containers own the array data and its scope controls the life of that data.

n-Dimensional Containers Overview

Multi-dimensional containers generalize ideas from 1-dimensional containers; they separate multi-dimensional access semantics from storage logic in an abstract way. A multi-dimensional SDLT container is a generic container that handles an arbitrary number of dimensions, and at the same time internally represents data as needed. Unlike 1-dimensional containers, multi-dimensional containers are not resizable and don't have interfaces like that of `std::vector`. While 1-dimensional containers are like `std::vectors` with decoupled storage, multi-dimensional containers are more akin to arrays (statically sized or variable length).

Below is an example of an n-dimensional container parameterized by three concerns: the data item (primitive) type, the storage layout in memory, and the observed shape of the container.

```
n_container<PrimitiveT, LayoutT, ExtentsT>
```

Template Arguments	Description
`typename PrimitiveT`	The type of primitive that will be contained.
`typename LayoutT`	The type of data layout.
`typename ExtentsT`	Specifies the dimensions of the container

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Construct an n_container

Description

An N-dimensional (multi-dimensional) container must be constructed before it can be used. The data type to be contained must first be declared as a `SDLT_PRIMITIVE`, then a data layout is chosen, and finally the shape of the container is determined describing the extents of each dimension.

Specify Data Layout

Rather than defining different containers for different data layouts, the data layout to use is specified as a template parameter to the container.

Available layouts are summarized in table below. Full details can found on the table in the topic n_container.

Layout	Description
`layout::soa<>`	Structure of Arrays (SOA). Each data member of the Primitive will have its own N-dimensional array.
`layout::soa_per_row<>`	Structure of Arrays Per Row. Each data member of the Primitive will have its own 1-dimensional array per row. Layout repeats for remaining N-1 dimensions.
`layout::aos_by_struct`	Array of Structures (AOS) Accessed by Struct. Native AOS layout and data access.
`layout::aos_by_stride`	Array of Structures Accessed by Stride. Native SOA data access through pointers to the built in types of members using a stride to account for the size of the Primitive.

Numbers and Constants

In order to define shape, integer values can be provided in three different forms, each successively providing less information to compiler. It is advised to use as precise specification as possible. The compiler may optimize better with more information.

Integer Value Specification	Description

`fixed<int NumberT>`	Known at compile time.
	`foo(fixed<1080>(), fixed<1920>());`
	The suffix `_fixed` will declare an equivalent literal. For example, `(1080_fixed` is equivalent to `fixed<1080>`.
	`foo(1080_fixed, 1920_fixed); )`

`aligned<int AlignmentT>(number)`	Programmer guarantees the number is a multiple of the `AlignmentT`. `foo(aligned<8>(height), aligned<128>(width));`
`“int”`	Arbitrary integer value. `foo(width, height);`

Specify Container Shape

`n_extent_t<…>` is a variadic template that accepts any number of arguments defining dimensions. Because construction using this type may look unclear, a generator object, `n_extent` , is provided to construct extents for all dimensions using a familiar array-definition-like syntax. Extent values may be specified using the most precise representation possible, as described above, to allow the compiler to better prove any potential data alignments.

```
n_extent[height][width];                  // OK
n_extent[height][aligned<128>(width)];  // Better
n_extent[1080_fixed][1920_fixed];       // Best
```

Define an n_container

Using a previously declared primitive (same as SDLT v1),

```
struct RGBAs { float red, green, blue, alpha; };
SDLT_PRIMITIVE(RGBAs, red, green, blue, alpha)
```

A two-dimensional container of RGBAs with HD image size 1920x0180 can be declared and instantiated as in the below example.

```
typedef n_container<RGBAs, layout::soa,
                    n_extent_t<fixed<1080>, fixed<1920>>> HdImage;
HdImage image1;
```

If sizes are not known, a container may be defined with extents unknown to the compiler but known at run-time when an instance of the container is created.

```
typedef n_container<RGBAs, layout::soa, n_extent_t<int, int>> Image;
Image image2(n_extent[height][width]);
```

Additionally, the templated factory function make_n_container<PrimitiveT, LayoutT> may be used to create containers.

```
auto image1 = make_n_container<RGBAs,
                          layout::soa>(n_extent[1080_fixed][1920_fixed]);
auto image2 = make_n_container<RGBAs,
                           layout::soa>(n_extent[height][width]);
```

Access Cells

Containers own data. To get to the data inside, use an "accessor."

```
auto ca = image1.const_access();
auto a = image2.access();
```

Specify the index for each dimension with a series of calls to the array subscript operator [], similar to a multi-dimensional array in C.

```
RGBAs pixel = ca[y][x];
float greyscale = (pixel.red + pixel.green + pixel.blue)/3;
a[y][x] = RGBAs(greyscale, greyscale, greyscale);
```

Discover Extents

Accessors know their extents.

Use template function `extent_d<int DimensionT>(object).`

```
for (int y = 0; y < extent_d<0>(ca); ++y)
    for (int x = 0; x < extent_d<1>(ca); ++x) {
          RGBAs pixel = ca[y][x];
         // …
    }
```

For convenience, non-template methods are also provided.

```
for (int y = 0; y < ca.extent_d0(); ++y)
    for (int x = 0; x < ca.extent_d1(); ++x) {
          RGBAs pixel = ca[y][x];
         // …
    }
```

Lower Dimensions

The result of not specifying all the dimensions required by an accessor is a new accessor with a lower rank that can then be accessed.

```
auto cay = ca[y];
RGBAs pixel = cay[x];
```

Bounds

Description

`bounds_t<LowerT, UpperT>` holds the lower and upper bounds of a half-open interval. It is templated to allow the different integer representations for the lower and upper bounds. The intent is to model a valid iteration space over a single dimension.

Bounds can be used to iterate over an entire extent or to restrict iteration space within an extent

Creating Bounds

Bounds can be created using full bounds_t type, but this may be tedious.

```
bounds_t<int, int>(start, finish)
bounds_t<int, aligned<16>>(start, aligned<16>(finish))
bounds_t<fixed<0>, fixed<1920>>()
```

It is simpler and clearer to use factory function bounds to build a bounds_t<>.

```
bounds(start,finish);
bounds(start, aligned<16>(finish));
bounds(0_fixed, 1920_fixed)
```

Discovering Bounds

Accessors know their valid iteraton space. Initial bounds for an accessor are set to set the lower bound to be fixed<0> and the upper bound set to the value and type of the dimension's extent as specified during construction of the n_container(fixed<>,aligned<>, or int).

To query bounds for given dimension of the accessor use template function `bounds_d<int DimensionT>(object)`.

```
auto b0 = bounds_d<0>(ca);
auto b1 = bounds_d<1>(ca);
for (int y = b0.lower(); y < b0.upper(); ++y)
    for (int x = b1.lower(); x < b1.upper(); ++x) {
          RGBAs pixel = ca[y][x];
         // …
    }
```

`bounds_t` can participate in C++11 range-based for loops.

```
for (auto y: bounds_d<0>(ca))
    for (auto x: bounds_d<1>(ca)) {
          RGBAs pixel = ca[y][x];
         // …
    }
```

```
for (auto y: ca.bounds_d0())
    for (auto x: ca.bounds_d1()) {
          RGBAs pixel = ca[y][x];
         // …
    }
```

N-Dimensional Indexes and Bounds

To model index and bounds values over multiple dimensions, respectively the following template classes are provided: `n_index_t<…>` and `n_bounds_t<…>` . These are both variadic templates, accepting any number of arguments.

`n_index` is a generator to simplify creating instances of `n_index_t`.

```
n_index[540][960]
```

`n_bounds` is a generator to simplify creating instances of `n_bounds_t`.

```
n_bounds[bounds(540,1080)][bounds(960,1920)]
```

Alternatively, `n_bounds_t` can be defined in terms of a `n_index_t` and `n_extent_t`.

```
n_bounds(n_index[540][960], n_extent[540][960]);
```

Accessing Subsections

From a container's accessors, a new accessor can be created over a subsection defined by a `n_bounds_t`.

```
auto ca = c.const_access();
auto subsect = ca.section(n_bounds[bounds(540, 1080)][bounds(960,1920)]);
```

The effect is to restrict the results of `bounds_d<int Dimension>` on the subsection accessor.

You can create a new accessor translated to a different index space.

```
auto offsetnewSpace = ca.translated_to(n_index[1000][2000]);
auto zeroSpace = ca.translated_to_zero();
```

Accesses will have a translation applied that maps the `n_index` back to the lower bounds of the accessor that created it. This allows a smaller container to be reused in a larger index space that is being walked over by blocks, or to move a subsection index space back to the origin.

User-Level Interface

This section describes the user-level interface for the SIMD Data Layout Templates (SDLT). This API is defined in `sdlt.h` and its associated header files.

SDLT Primitives (SDLT_PRIMITIVE)

Primitives represent the data we want to work over in SIMD. They can be more than just data structures. As a C++ object, it can have its own methods that modify its data.

Rules:

- Must be Plain Old Data (POD)
  - Has trivial copy constructor

  - Has trivial move constructor
  - Has trivial destructor
  - No virtual functions or virtual bases
- No reference data members
- No unions
- No bit fields
- No bool types
  - Comparison semantics not efficient in SIMD
  - Use 32-bit integer and compare against known values like 0 or 1 explicitly
- Data members need to be public or declare `SDLT_PRIMITIVE_FRIEND` in the object's definition

Current limitations:

- No pointer data members
- No C++11 strongly typed enums—use integers instead.
- No array based data members.
- copy constructor and assignment operator (=) defined by individual member assignment—strongly encouraged to facilitate better code generation

They may seem like large restrictions, but often code can easily be re-factored to meet this requirement. For example:

```
class Point3d {
    // methods...
protected:
    double v[3];
};
```

can be re-factored to have a public data member for each element in the array and update methods to use the `x`, `y`, and `z` data members rather than the array `v`.

```
class Point3d {
public:
    // methods...
    double x;
    double y;
    double z;
};
```

For better code generation, explicitly define a copy constructor and assignment operator (=) by individual member assignment.

`SDLT_PRIMITIVE` Macro

Once an object meets the criteria above, we can consider it a Primitive type in SDLT. In order for Container's to import and export the Primitive, it has to understand its data layout. Unfortunately C++11 lacks compile time reflection, so the user must provide SDLT with a description of your structure's data layout. This is easily done with the SDLT_PRIMITIVE helper macro that accepts a struct type followed by a comma separated list of its data members.

```
SDLT_PRIMITIVE(STRUCT_NAME, DATA_MEMBER_1, ...)
```

Example Usage:

```
struct UserObject
{
    float x;
    float y;
    double acceleration;
    int behavior;
};

SDLT_PRIMITIVE(UserObject, x, y, acceleration, behavior)
```

An object must be declared as a Primitive before it can be used in a Container. However, built-in types like float, double, int, etc. do not need to be declared as a Primitive before use with a Container. Built-in's are automatically considered Primitives by SDLT.

Nested Primitives are supported, but the nested Primitive must be declared before the outer Primitive is. Example: Axis Aligned Bounding Box made up of two 3d points

```
struct Point3s
{
    float x;
    float y;
    float z;
};

struct AABB
{
    Point3s topLeft;
    Point3s bottomRight;
};

SDLT_PRIMITIVE(Point3s, x, y, z)
SDLT_PRIMITIVE(AABB, topLeft, bottomRight)
```

Notice the `struct` definitions themselves do not derive from SDLT or use any of its nomenclature. This independence allows classes to be used in code not using SDLT and only code that does use SDLT Containers needs to see the Primitive declarations.

soa1d_container

Template class for "Structure of Arrays" memory layout of a one-dimensional container of Primitives.
`#include <sdlt/soa1d_container.h>`

Syntax

```
template<typename PrimitiveT,
         int AlignD1OnIndexT = 0,
         class AllocatorT = allocator::default_alloc>
class soa1d_container;
```

Arguments

`typename PrimitiveT`	The type that each element in the array will store
`int AlignD1OnIndexT = 0`	[Optional] The index on which the data access will be aligned (useful for stencils)
`class AllocatorT = allocator::default_alloc`	[Optional] Specify type of allocator to be used. `allocator::default_alloc` is currently the only allocator supported.

Description

Dynamically sized container of Primitive elements with memory layout as a Structure of Arrays internally providing:

- Dynamic resizing with interface similar to `std::vector`
- Accessor objects suitable for efficient data access inside SIMD loops

Member	Description
`typedef size_t size_type;`	Type to use when specifying sizes to methods of the container.
`template <typename OffsetT = no_offset>` `using accessor;`	Template alias to an accessor for this container
`template <typename OffsetT = no_offset >` `using const_accessor;`	Template alias to an const_accessor for this container

Member Type	Description

`soa1d_container(`
`    size_type size_d1 = 0u,`
`    buffer_offset_in_cachelines buffer_offset`
`        = buffer_offset_in_cachelines(0),`
`    const allocator_type & an_allocator =`
`allocator_type());`
	Constructs an uninitialized container of size_d1 elements, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

`soa1d_container(`
`    size_type size_d1,`
`    const PrimitiveT &a_value,`
`    buffer_offset_in_cachelines buffer_offset`
`        = buffer_offset_in_cachelines(0),`
`    const allocator_type & an_allocator`
`        = allocator_type());`
	Constructs a container of size_d1 elements initializing each with a_value, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

`template<typename StlAllocatorT>`
`soa1d_container(`
`    const std::vector<PrimitiveT,`
`StlAllocatorT> &other,`
`    buffer_offset_in_cachelines buffer_offset`
`        = buffer_offset_in_cachelines(0),`
`    const allocator_type & an_allocator`
`        = allocator_type());`
	Constructs a container with a copy of each of the elements in other, in the same order, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

`soa1d_container(`
`    const PrimitiveT *other_array,`
`    size_type number_of_elements,`
`    buffer_offset_in_cachelines buffer_offset`
`        = buffer_offset_in_cachelines(0),`
`    const allocator_type & an_allocator`
`        = allocator_type());`
	Constructs a container with a copy of number_of_elements elements from the array other_array, in the same order, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

`template< typename IteratorT >`
`soa1d_container(`
`    IteratorT a_begin,`
`    IteratorT an_end,`
`    buffer_offset_in_cachelines buffer_offset`
`        = buffer_offset_in_cachelines(0),`
`    const allocator_type & an_allocator`
`        = allocator_type());`
	Constructs a container with as many elements as the range [a_begin - an_end), each with a copy of the value from its corresponding element in that range, in the same order, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

`soa1d_container clone() const;`	Returns: a new soa1d_container instance with its own copy of the elements

Member Type	Description
`void resize(size_type new_size_d1);`	Resize the container so that it contains *new_size_d1* elements. If the new size is greater than the current container size, the new elements are unitialized.
`accessor<> access();`	Returns: accessor with no embedded index offset.
`accessor<int> access(int offset);`	Returns: accessor with an integer based embedded index offset.
`template<int IndexAlignmentT> accessor<aligned_offset<IndexAlignmentT> > access(aligned_offset<IndexAlignmentT>);`	Returns: accessor with an aligned_offset<IndexAlignmentT> based embedded index offset.
`template<int OffsetT> accessor<fixed_offset<OffsetT> > access(fixed_offset<OffsetT>);`	Returns: accessor with a fixed_offset<OffsetT> based embedded index offset.
`const_accessor<> const_access() const;`	Returns: const_accessor with no embedded index offset.
`const_accessor<int> const_access(int offset) const;`	Returns: const_accessor with an integer based embedded index offset.
`const_accessor<aligned_offset<IndexAlignmentT> > const_access(aligned_offset<IndexAlignmentT> offset) const;`	Returns: const_accessor with an aligned_offset<IndexAlignmentT> based embedded index offset.
`template<int OffsetT> const_accessor<fixed_offset<OffsetT> > const_access(fixed_offset<OffsetT>) const;`	Returns: const_accessor with a fixed_offset<OffsetT> based embedded index offset.

STL Compatibility

In addition to the performance oriented interface explained in the table above, `soa1d_container` implements a subset of the `std::vector` interface that is intended for ease of integration, not high performance. Due to the import/export only requirement we can't return a reference to the object, instead `iterators` and `operator[]` return a Proxy object while other "const' methods return a "value_type const". Futhermore, iterators do not support the `->` operator. Despite that limitation the iterators can be passed to any STL algorithm. Also for performance reasons, resize does not initialize new elements. The following `std::vector` interface methods are implemented:

- size, max_size, capacity, empty, reserve, shrink_to_fit
- assign, push_back, pop_back, clear, insert, emplace, erase
- cbegin, cend, begin, end, begin, end, crbegin, crend, rbegin, rend, rbegin, rend
- operator[], front() const, back() const, at() const
- swap, ==, !=
- swap, soa1d_container(soa1d_container&& donor), soa1d_container & operator=(soa1d_container&& donor)

aos1d_container

Template class for "Array of Structures" memory layout of a one-dimensional container of Primitives.

#include <sdlt/aos1d_container.h>

Syntax

```
template<
    typename PrimitiveT,
    AccessBy AccessByT,
    class AllocatorT = allocator::default_alloc
>
class aos1d_container;
```

Arguments

`typename PrimitiveT`	The type that each element in the array will store
`access_by AccessByT`	Enum to control how the memory layout will be accessed. Recommend access_by_struct unless you are having issues vectorizing. See the documentation of `access_by` for more details
`class AllocatorT = allocator::default_alloc`	[Optional] Specify the type of allocator to be used. `allocator::default_alloc` is currently the only allocator supported.

Description

Provide compatible interface with `soa1d_container` while keeping the memory layout as an Array of Structures internally. User can easily switch between data layouts by changing the type of container they use. The rest of the code written against accessors and proxy elements and members can stay the same.

- Dynamic resizing with interface similar to `std::vector`
- Accessor objects suitable for efficient data access inside SIMD loops

Member	Description
`typedef size_t size_type;`	Type to use when specifying sizes to methods of the container.
`template <typename OffsetT = no_offset> using accessor;`	Template alias to an `accessor` for this container
`template <typename OffsetT = no_offset> using const_accessor;`	Template alias to a `const_accessor` for this container

Member Type	Description
`aos1d_container( size_type size_d1 = 0u, buffer_offset_in_cachelines buffer_offset = buffer_offset_in_cachelines(0), const allocator_type & an_allocator = allocator_type());`	Constructs an uninitialized container of size_d1 elements, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

Member Type	Description

`aos1d_container (`
`    size_type size_d1,`
`    const PrimitiveT &a_value,`
`    buffer_offset_in_cachelines buffer_offset`
`        = buffer_offset_in_cachelines(0),`
`    const allocator_type & an_allocator`
`        = allocator_type());`
	Constructs a container of *size_d1* elements initializing each with *a_value*, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

`template<typename StlAllocatorT>`
`aos1d_container(`
`    const std::vector<PrimitiveT,`
`StlAllocatorT> &other,`
`    buffer_offset_in_cachelines buffer_offset`
`        = buffer_offset_in_cachelines(0),`
`    const allocator_type & an_allocator`
`        = allocator_type());`
	Constructs a container with a copy of each of the elements in *other*, in the same order, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

`aos1d_container(`
`    const PrimitiveT *other_array,`
`    size_type number_of_elements,`
`    buffer_offset_in_cachelines buffer_offset`
`        = buffer_offset_in_cachelines(0),`
`    const allocator_type & an_allocator`
`        = allocator_type());`
	Constructs a container with a copy of *number_of_elements* elements from the array *other_array*, in the same order, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

`template< typename IteratorT >`
`aos1d_container(`
`    IteratorT a_begin,`
`    IteratorT an_end,`
`    buffer_offset_in_cachelines buffer_offset`
`        = buffer_offset_in_cachelines(0),`
`    const allocator_type & an_allocator`
`        = allocator_type());`
	Constructs a container with as many elements as the range [*a_begin*-*an_end*), each with a copy of the value from its corresponding element in that range, in the same order, using optionally specified allocator instance, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing.

`aos1d_container clone() const;`	Returns: a new *aos1d_container* instance with its own copy of the elements
`void resize(size_type new_size_d1);`	Resize the container so that it contains *new_size_d1* elements. If the new size is greater than the current container size, the new elements are unitialized
`accessor<> access();`	Returns: *accessor* with no embedded index *offset*.
`accessor<int> access(int offset);`	Returns:*accessor* with an integer based embedded index *offset*.

`template<int IndexAlignmentT>`
`accessor<aligned_offset<IndexAlignmentT> >`
`    access(aligned_offset<IndexAlignmentT>);`
	Returns: *accessor* with an aligned_offset<IndexAlignmentT> based embedded index *offset.*

`template<int OffsetT>`
`accessor<fixed_offset<OffsetT> >`
`    access(fixed_offset<OffsetT>);`
	Returns: *accessor* with a fixed_offset<OffsetT> based embedded index *offset*.

Member Type	Description
`const_accessor<> const_access() const;`	Returns: *const_accessor* with no embedded index offset.
`const_accessor<int> const_access(int offset) const;`	Returns: *const_accessor* with an integer based embedded index *offset.*
`const_accessor<aligned_offset<IndexAlignmentT> > const_access(aligned_offset<IndexAlignmentT> offset) const;`	Returns:*const_accessor* with an aligned_offset<IndexAlignmentT> based embedded index *offset*.
`template<int OffsetT> const_accessor<fixed_offset<OffsetT> > const_access(fixed_offset<OffsetT>) const;`	Returns:*const_accessor* with a fixed_offset<OffsetT> based embedded index *offset*.

STL Compatibility

In addition to the performance oriented interface explained in the table above, `aos1d_container` implements a subset of the `std::vector` interface that is intended for ease of integration, not high performance. Due to the import/export only requirement we can't return a reference to the object, instead `iterators` and `operator[]` return a Proxy object while other "const' methods return a "value_type const". Furthermore, iterators do not support the `->` operator. Despite that limitation the iterators can be passed to any STL algorithm. Also for performance reasons, resize does not initialize new elements. The following `std::vector` interface methods are implemented:

- size, max_size, capacity, empty, reserve, shrink_to_fit
- assign, push_back, pop_back, clear, insert, emplace, erase
- cbegin, cend, begin, end, crbegin, crend, rbegin, rend, rbegin, rend
- operator[], front() const, back() const, at() const
- swap, ==, !=
- swap, aos1d_container(aos1d_container&& donor), aos1d_container & operator=(aos1d_container&& donor)

access_by

Enum to control how the memory layout will be accessed. `#include <sdlt/access_by.h>`

Syntax

```
enum access_by
{
    access_by_struct,
    access_by_stride
};
```

Description

The `access_by_struct` causes data access via structure member access. Nested structures will drill down through the structure members in a nested manner. For example an Axis Aligned Bounding Box (AABB) containing two Point3d objects (with x,y,z data members) will logically expand to something like:

```
AABB local;
local = accessor.mData[i];
```

access_by_stride will cause data access through pointers to built in types with a stride to account for the size of the primitive. For an Axis Aligned Bounding Box (AABB) containing two Point3d objects (with x,y,z data members) will logically expand to something like:

```
AABB local;
local.topLeft.x = *(accessor.mData + offsetof(AABB,topLeft) + offset(Point3d,x) +
(sizeof(AABB)*i));
local.topLeft.y = *(accessor.mData + offsetof(AABB,topLeft) + offset(Point3d,y) +
(sizeof(AABB)*i));
local.topLeft.z = *(accessor.mData + offsetof(AABB,topLeft) + offset(Point3d,z) +
(sizeof(AABB)*i));
local.topRight.x = *(accessor.mData + offsetof(AABB,topRight) + offset(Point3d,x) +
(sizeof(AABB)*i));
local.topRight.y = *(accessor.mData + offsetof(AABB,topRight) + offset(Point3d,y) +
(sizeof(AABB)*i));
local.topRight.z = *(accessor.mData + offsetof(AABB,topRight) + offset(Point3d,z) +
(sizeof(AABB)*i));
```

When vectorizing, access_by_struct can sometimes generate better code as the compiler could perform wide loads and use shuffle/insert instructions to move data into SIMD registers. However, depending on the complexity of the primitive, it can also fail to vectorize, especially when the primitive contains nested structures.

On the other hand access_by_stride has always vectorized successfully, because the data access is simplified to an array pointer with a stride. The compiler is able to handle any complexity of primitive, because it never sees the complexity and instead just sees the simple array pointer with strided access.

access_by_struct is probably the best choice as it offers a chance of better code generation especially when used outside of a SIMD loop. However if you run into issues when vectorizing, try access_by_stride to see if that alleviates the problem.

We leave this choice up to the developer and require they explicitly make a choice, so this is not hidden behavior.

n_container

Template class for N-dimensional container. The contained primitive type, exact memory layout and container shape are defined via template arguments.

Syntax

```
template <typename PrimitiveT,
          typename LayoutT,
          typename ExtentsT,
          typename AllocatorT >
class n_container;
```

Description

N-dimensional container of PrimitiveT elements with predefined memory layout and shape. Provides accessor interface suitable for flexible and efficient data access inside SIMD loops

The following table provides information on the template arguments for n_container

Template Argument	Description
`typename PrimitiveT`	The type that each cell in the multi-dimensional container will store. Requirements: PrimitiveT must be previously declared with the SDLT_PRIMITIVE macro.

Template Argument	Description
`typename LayoutT`	The in-memory data layout of cells in the container. Requirements: LayoutT must be a class from *layout* namespace.
`typename ExtentsT`	The shape of the container. Requirements: ExtentsT must be a concrete type of *n_extent_t* variadic template.
`class AllocatorT = allocator::default_alloc`	[Optional] Specify type of *allocator* to be used. allocator::default_alloc is currently the only allocator supported.

The following table provides information on the types defined as members of `n_container`

Member Type	Description
`typedef PrimitiveT primitive_type;`	Type inside each cell of the container.
`typedef PrimitiveT allocator_type;`	Type of allocator used by the container.
`typedef implementation-defined accessor`	Type of an *accessor* that can write or read cells to and from this container.
`typedef implementation-defined const_accessor;`	Type of a *const_accessor* that can read cells from this container.

The following table provides information on the methods of `n_container`

Member	Description
`n_container ( const ExtentsT &a_extents, buffer_offset_in_cachelines buffer_offset =buffer_offset_in_cachelines(0), const AllocatorT &an_allocator=AllocatorT())`	Constructs an uninitialized container of the shape defined as *a_extents*, using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing, using optionally specified allocator instance.
`n_container (buffer_offset_in_cachelines buffer_offset = buffer_offset_in_cachelines(0), const AllocatorT &an_allocator=AllocatorT())`	Constructs an uninitialized container of the shape, defined via template parameter ExtentsT using optionally specified number of cache lines to offset the start of the buffer in memory to allow management of 4k cache aliasing, using optionally specified allocator instance. ExtentsT must be default constructible. Only true when ExtentsT is made up enitrely of fixed<NumberT> types.
`n_container(n_container&& donor)`	Transfers ownership of the donor's currently owned buffers and organization, if any. Any outstanding *accessors* on the donor are no longer valid.

Member	Description
`n_container & operator = (n_container&& donor)`	Frees any existing buffers, then transfers ownership of the donor's currently owned buffers and organization, if any. Any outstanding *accessors* on the donor are no longer valid. **Returns:** Reference to this instance.
`const ExtentsT& n_extent () const`	Provides the shape of the container. Alternatively, the free template function *extent_d<int DimenstionT>(const n_container &)* could be used. **Returns:** Constant reference to ExtentsT instance describing the shape of the container.
`const_accessor const_access();`	Constructs an *const_accessor* with knowledge of the underlying data organization to read cells inside the container. **Returns:***const_accessor* for the container
`accessor access();`	Constructs an *accessor* with knowledge of the underlying data organization to write or read cells inside the container. **Returns:***accessor* for the container

The following table provides information about the friend functions of n_container.

Friend Function	Description
`std::ostream& operator << (std::ostream& output_stream, const n_container & a_container)`	Append string representation of a_container's extents values to a_output_stream. **Returns:** Reference to a_output_stream for chained calls.

Layouts

sdlt::layout namespace

Rather than having different container types for different data layouts, the library uses the types from the layout namespace as a template parameter to the n_container.

Available layouts are defined in the namespace layout and summarized in table below.

Layout	Description
`template <typename AlignOnColumnIndexT=0> layout::soa`	Structure of Arrays: Each data member of the Primitive will have its own N-dimensional array. The arrays are placed back-to-back inside a contiguous buffer. Template parameter AlignOnColumnIndexT identifies which column of the row dimension should be cache line aligned. The AlignOnColumnIndexT of each row is cache line aligned.
`template <typename AlignOnColumnIndexT> layout::soa_per_row`	Structure of Arrays Per Row: Each data member of the Primitive will have its own 1-dimensional array for the row dimension (Soa1d) placed back to back. The AlignOnColumnIndexT of each row is cache line aligned. Multiple of these Soa1d's are laid out

Layout	Description
	sequentially to model the remaining dimensions, effectively becoming an Array of Structures of Arrays where the SOA where the size of the array is the row's extent. This can be particularly efficient when the extent of the row can be fixed<NumberT>. **Note**: If the size of the row isn't known at compile time, consider adding an additional dimension that is fixed<Number> and dividing the row up by that fixed<NumberT>.
`layout::aos_by_struct`	Array of Structures Accessed by Struct: Primitives are laid out in native format back to back in memory and access happens via structure or member access. Nested structures will drill down through the structure members in a nested manner.
`layout::aos_by_stride`	Array of Structures Accessed by Stride: Primitives are laid out in native format back to back in memory and accessed through pointers to built in types with a stride to account for the size of the Primitive. Can be useful if aos_by_struct doesn't vectorize.

Description

The classes are empty and only for specialization of containers for denoted layouts.

Shape

Variadic template class n_extent_t describes the shape of the n_dimensional container. Specifically, the number of dimensions the size of each.

Syntax

```
template<typename... TypeListT>
class n_extent_t
```

Description

`n_extent_t` represents the shape of a container as a sequence of sizes for each dimension. The size of each dimension can be represented by different types. This flexibility allows the same interface to be used to declare `n_extents_t` whose dimensions are fully known at compile time with `fixed<int NumberT>`, or to be only known at runtime with `int`, or only known at runtime but with a guarantee will be a multiple of an alignment with `aligned<int Alignment>`. For details, see the Number representation section.

The following table provides information on the template arguments for `n_extent_t`.

Template Argument	Description
`typename... TypeListT`	Comma separated list of types, where the number of types provided controls how many dimensions there are. Each type in the list identifies how the size of the corresponding dimension is to be represented. The order of the dimensions is the same order as C++ subscripts declaring a multi-dimensional array, from leftmost to rightmost.

Template Argument	Description
	Type must be `int`, `fixed<NumberT>`, or `aligned<AlignmentT>`. for each value describing corresponding dimensions size (extent) in regular order of C++ subscripts - from outer to inner.

The following table provides information on the members of `n_extent_t`

Member	Description
`static constexpr int rank;`	Number of dimensions.
`static constexpr int row_dimension = rank-1;`	Index of last dimension, *row.*
`n_extent_t()`	**Requirements:** Every type in TypeListT is default constructible. **Effects:** Construct n_extent_t, uses default values of each type in TypeListT for the dimesnion sizes. In general, only correctly initialized when every type is a fixed<NumberT>
`n_extent_t(const n_extent_t &a_other)`	**Effects:** Construct n_exent_t, copying size of each dimension from *a_other*.
`explicit n_extent_t(const TypeListT & … a_values)`	**Effects:** Construct n_exent_t, initializing each dimension with the corresponding value from the list of *a_values* passed as an argument. In use, *a_values* is a comma separate list of values whose length and types are defined by TypeListT.
`template<int DimensionT> auto get() const`	**Requirements:** DimenstionT >=0 and DimensiontT < rank. **Effects:** Determine the exent of *DimensionT*. **Returns:** In the type declared by the *DimensionT* position of 0-based TypeListT, the extent of the specified *DimensionT*
`template<int DimensionT>` `auto rightmost_dimensions() const`	**Requirements:** DimenstionT >=0 and DimensiontT <= rank. **Effects:** Construct a n_extent_t with a lower rank by copying the righmost DimensionT values from this instance. **Returns:** n_exent[get<rank - DimensionT>()] [get<rank + 1 - DimensionT>()] [get<…>()] [get<row_dimension>()]

`template<class... OtherTypeListT>`
`bool operator == (const`
`n_extent_t<OtherTypeListT...> a_other) const`
	Requirements: rank of a_other is the same as this instance's.

Member	Description
	Effects: Compare size of each dimension for equality. Only compares numeric values, not the types of each dimension. **Returns:***true* if all dimensions are numerically equal, *false* otherwise.
`template<class... OtherTypeListT> bool operator != (const n_extent_t<OtherTypeListT...> a_other) const`	**Requirements:** rank of a_other is the same as this instance's. **Effects:** Compare size of each dimension for inequality. Only compares numeric values, not the types of each dimension. **Returns:***true* if any dimensions are numerically different, *false* otherwise.
`size_t size() const`	**Returns:** Number of elements specified by extent **Effects:** Calculates the number of cells represented by the current extent values of each dimension by multiplying them all together. **Returns:** get<0>()*get<1>()*get<…>()*get<rank-1>()

The following table provides information on the friend functions of `n_extent_t`.

Friend function	Description
`std::ostream& operator << (std::ostream& output_stream, const n_extent_t & a_extents)`	**Effects:** Append string representation of a_extents' values to a_output_stream **Returns:** Reference to a_output_stream for chained calls.

n_extent_generator
To facilitate simpler and clearer creation of `n_extent_t` *objects.*

Syntax

```
template<typename... TypeListT>
class n_extent_generator;

namespace {
    // Instance of generator object
    n_extent_generator<> n_extent;
}
```

Description

The generator object provides recursively constructing operators [] for `fixed<>`, `aligned<>`, and `integer` values allowing building of an `n_extent_t` <…> instance, one dimension at a time. The main purpose is to allow a usage syntax that is similar to C multi-dimensional array definition:

Compare the following examples, instantiating three n_extent_t instances. and using the generator object to instantiate equivalent instances.

```
n_extent_t<int, int> ext1(height, width);
n_extent_t<int, aligned<128>> ext2(height, width);
n_extent_t<fixed<1080>, fixed<1920>> ext3(1080_fixed, 1920_fixed);
```

```
auto ext1 = n_extent[height][width];
auto ext2 = n_extent[height][aligned<128>(width)];
auto ext3 = n_extent[1080_fixed][1920_fixed];
```

Class Hierarchy

It is expected that n_extent_generator < … > not be directly used as a data member or parameter, instead only n_extent_t <...> from which it is derived. The generator object n_extent can be automatically downcast any place expecting an n_extent_t<…> .

The following table provides the template arguments for n_extent_generator

Template Argument	Description
typename... TypeListT	Comma separated list of types, where the number of types provided controls how many dimensions the generator currently represent. Each type in the list identifies how the size of the corresponding dimension is to be represented. The order of the dimensions is the same order as C++ subscripts declaring a multi-dimensional array – from leftmost to rightmost. **Requirements**: Type is int, fixed<NumberT>, or aligned<AlignmentT>.

The following table provides information on the types defined as members of n_extent_generator in addition to those inherited from n_extent_t.

Member Type	Description
typedef n_extent_t<TypeListT...> value_type	Type value that the any chained [] operator calls have produced.

The following table provides information on the members of n_extent_generator in addition to those inherited from n_extent_t

Member	Description
n_extent_generator ()	**Requirements:** TypeListT is empty **Effects:** Construct generator with no extents specified
n_extent_generator (const n_extent_generator &a_other)	**Effects:** Construct generator copying any extent values from a_other
n_extent_generator<TypeListT..., int> operator [] (int a_size) const	**Requirements:** a_size >= 0 **Returns:** n_extent_generator<…> with additional rightmost integer based extent.
n_extent_generator<TypeListT..., fixed<NumberT>> operator [] (fixed<NumberT> a_size) const	**Requirements:** a_size >= 0 **Returns:** n_extent_generator<…> with additional rightmost fixed<NumberT> extent.

Member	Description
`n_extent_generator<TypeListT..., aligned<AlignmentT>> operator [] (aligned<AlignmentT> a_size)`	**Requirements:** a_size >= 0 **Returns:** n_extent_generator<...> with additional rightmost aligned<AlignmentT> based extent.
`value_type value() const`	**Returns:** n_extent_t<...> with the correct types and values of the multi-dimensional extents aggregated by the generator.

make_ n_container template function

Factory function to construct an instance of a properly-typed n_container<...> based on n_extent_t passed to it.

Syntax

```
template<
    typename PrimitiveT,
    typename LayoutT,
    typename AllocatorT = allocator::default_alloc,
    typename ExtentsT
>
auto make_n_container(const ExtentsT &_extents)
->n_container<PrimitiveT, LayoutT, ExtentsT, AllocatorT>
```

Description

Use `make_n_container` to more easily create an n-dimensional container using template argument deduction, and avoid specifying the type of extents.

An example of the instantiation of a High Definition image object is below.

```
typedef n_container<RGBAs, layout::soa,
                    n_extent_t<int, int>> HdImage;
HdImage image1(n_extent[1080][1920]);
```

Alternatively, it is possible to use factory function with the C++11 keyword `auto`, as shown below.

```
auto image1 = make_n_container<RGBAs,
                          layout::soa>(n_extent[1080][1920]);
```

extent_d template function

Syntax

```
template<int DimensionT, typename ObjT>
auto extent_d(const ObjT &a_obj)
```

Description

The template function offers a consistent way to determine the extent of a dimension for a multi-dimensional object. It can avoid extracting an entire n_extent_t<...> when only the extent of a single dimension is needed.

Template Argument	Description
`int DimensionT`	0 based index starting at the leftmost dimension indicating which n-dimensions to query the extent of.

Template Argument	Description
	Requirements: DimensionT >=0 and DimensionT < ObjT::rank
`typename ObjT`	The type of n-dimensional object from which to retrieve the extent. **Requirements:** ObtT is one of: n_container<…> n_extent_t<…> n_extent_generator<…>

Returns

The correctly typed extent corresponding to the requested DimensionT of a_obj.

Example

```
template <typename VolumeT>
void foo(const VolumeT & a_volume)
{
    int extent_z = extent_d<0>(volume);
    int extent_y = extent_d<1>(volume);
    int extent_x = extent_d<2>(volume);
    /…
}
```

Bounds

bounds_t

Class represents a half-open interval with lower and upper bounds. `#include <sdlt/bounds.h>`

Syntax

```
template<typename LowerT = int, typename UpperT = int>
struct bounds_t
```

Description

bounds_t holds the lower and upper bounds of a half open interval. It is templated to allow the different representations for the lower and upper bounds. Supported types include fixed<NumberT>, aligned<AlignmentT> and integer values. bounds_t models a valid iteration space over a single dimension.

bounds_t can be used to represent an iteration space over the entire extent of a dimension or to restrict iteration space within the extent. n_bounds_t aggregates a number of bounds_t objects to allow construction of multi-demensional subsections restricting multiple extents.

The class interface is compatible with C++ range-based loops to simplify iteration.

Template Argument	Description
`typename LowerT = int`	Type of lower bound. Requirements: type is int, or fixed<NumberT>, or aligned<AlignmentT>
`typename UpperT = int`	Type of upper bound.

Template Argument	Description
	Requirements: type is int, or fixed<NumberT>, or aligned<AlignmentT>

Member Types	Description
`typedef LowerT lower_type`	Type of the lower bound
`typedef UpperT upper_type`	Type of the upper bound
`typedef implementation-defined iterator`	Iterator type for C++ range-based loops support.

Member	Description
`bounds_t()`	Effects: Constructs bounds_t with uninitialized lower and upper bounds.
`bounds_t(lower_type l, upper_type u)`	Requirements: (u >= l) Effects: Constructs bounds_t representing the half-open interval [l, u)
`bounds_t(const bounds_t & a_other)`	Effects: Constructs bounds_t with lower and upper bounds initialized from those of a_other.
`template<typename OtherLowerT, typename OtherUpperT>` `bounds_t(const bounds_t<OtherLowerT, OtherUpperT> & a_other)`	Requirements: OtherLowerT and OtherUpperT can legally be converted to lower_type and upper_type. For example it would be illegal to convert an int to fixed<8>(). Effects: Constructs bounds_t with lower and upper bounds initialized from those of a_other.
`void set(lower_type l, upper_type u)`	Effects: Set index of the inclusive lower bound and the index of the exclusive upper bound.
`void set_lower(lower_type a_lower)`	Effects: Set index of the inclusive lower bound
`void set_upper(upper_type a_upper)`	Effects: Set index of the exclusive upper bound
`lower_type lower() const`	Returns: index of the inclusive lower bound
`upper_type upper() const`	Returns: index of the exclusive upper bound
`iterator begin() const`	Returns: index iterator for the inclusive lower bound. NOTE: C++11 range-based loops require begin() & end()
`iterator end() const`	Returns: index iterator for the exclusive upper bound. NOTE: C++11 range-based loops require begin() & end()
`auto width() const`	Effects: Determine width of iteration space inside the half open interval between lower() and upper() bounds. Returns: upper() – lower()

Member	Description
	NOTE: the return type depends on resulting type of a subtraction between the types of upper() and lower().

template<typename OtherLowerT,
        typename OtherUpperT>
bool contains(const bounds_t<OtherLowerT,
                OtherUpperT> &a_other) const
	Effects: Determine if interval of a_other is entirely contained inside this object's bounds
	Returns: (a_other.lower() >= lower() &&
	a_other.upper() <= upper())

template<typename T> auto operator + (const T &offset) const	Effects: create a new bounds_t instance with offset added to both lower and upper bounds. Returns: bounds(lower() + offset, upper()+offset) NOTE: The lower_type and upper_type of the returned bound_t maybe different as result of addition of the offset.
template<typename T> auto operator - (const T & offset) const	Effects: create a new bounds_t instance with offset subtracted from both lower and upper bounds. Returns: bounds(lower() - offset, upper()-offset) NOTE: The lower_type and upper_type of the returned object maybe different as result of subtraction of T.
bool operator == (const bounds_t &a_other) const	Effects: Equality comparison with same-typed bounds_t object Returns: (lower() == a_other.lower() && upper() == a_other.upper())

template<typename OtherLowerT,
        typename OtherUpperT>
bool operator == (
 const bounds_t<OtherLowerT,
                OtherUpperT> &a_other) const
	Effects: Equality comparison with bounds_t object of different lower_type or upper_type.
	Returns: (lower() == a_other.lower() && upper() == a_other.upper())

bool operator != (const bounds_t &) const	Effects: Inequality comparison with same-typed bounds_t object Returns: (lower() != a_other.lower() || upper() != a_other.upper())

template<typename OtherLowerT,
        typename OtherUpperT>
bool operator != (
 const bounds_t<OtherLowerT,
                OtherUpperT> &a_other) const
	Effects: Inequality comparison with with bounds_t object of different lower_type or upper_type
	Returns: (lower() != a_other.lower() || upper() != a_other.upper())

Friend Function	Description
std::ostream& operator << (std::ostream& a_output_stream, const bounds_t &a_bounds)	Effects: append string representation of bounds_t lower and upper values to a_output_stream

Friend Function	Description
	Returns: reference to a_output_stream for chained calls

Range-based loops support

The bounds_t provides begin() and end() methods returning iterators to enable C++11 range-based loops. The may save quite some typing and improve code clarity when iterating over bounds of a multidimensional container.

Compare:

```
auto ca = image_container.const_access();
auto b0 = bounds_d<0>(ca);
auto b1 = bounds_d<1>(ca);
for (auto y = b0.lower(); y < b0.upper(); ++y)
    for (auto x = b1.lower(); x < b1.upper(); ++x) {
          RGBAs pixel = ca[y][x];
            // …
    }
```

and

```
auto ca = image_container.const_access();
for (auto y: bounds_d<0>(ca))
    for (auto x: bounds_d<1>(ca)) {
          RGBAs pixel = ca[y][x];
            // …
    }
```

Note that iterator only gives an index value within the bounds, not an object value. It is expected to be used to index into accessors like in example above.

sdlt::bounds Template Function

Factory function provided for creation of bounds_t objects. `#include <sdlt/bounds.h>`

Syntax

```
template<typename LowerT, typename UpperT>
auto bounds(LowerT a_lower, UpperT a_upper)
```

Description

In order to make creation of objects of bounds_t cleaner the factory function bounds is provided. It basically enables LowerT and UpperT to be deduced from the arguments passed into it.

Template Argument	Description
`typename LowerT = int`	Type of lower bound. Requirements: type is int, or fixed<NumberT>, or aligned<AlignmentT>
`typename UpperT = int`	Type of upper bound. Requirements: type is int, or fixed<NumberT>, or aligned<AlignmentT>

Returns:

The correctly typed bounds_t<LowerT, UpperT> corresponding to types of a_lower and a_upper passed to the factory function.

Example:

Compare two ways of instantiating a bounds:

```
bounds_t<fixed<0>, aligned<16>> my_bounds1(0_fixed, aligned<16>(upper))
auto my_bounds2 = bounds_t<fixed<0>, aligned<16>>(0_fixed, aligned<16>(upper))
```

With the factory function:

```
auto my_bounds = bounds(0_fixed, aligned<16>(upper))
```

n_bounds_t

Variadic template class to describe the valid iteration space over an N-dimensional container. `#include <sdlt/n_bounds.h>`

Syntax

```
template<typename... TypeListT>
class n_bounds_t
```

Description

n_bound_t represents the valid iteration space over a n_container or its accessor as as a sequence of bounds_t for each dimension. The bounds_t of each dimension can be represented by different types. This flexibility allows the same interface to be used to declare n_bounds_t whose dimensions are fully known at compile time with fixed<int NumberT>, or to be only known at runtime with int, or only known at runtime but with a guarantee will be a multiple of an alignment with aligned<int Alignment>. For details see the Number Representation section).

When an n_container is created, its n_bounds_t always start at fixed<0> for the inclusive lower bounds of each dimension, and exclusive upper bounds match the extent of the dimension. Accessors can be translated to different index spaces as well as restrict their iteration space to subsections, which will change the n_bounds_t those accessors provide.

The following table provides information on the template arguments for `n_bounds_t`.

Template Argument	Description
`typename... TypeListT`	Comma separated list of types, where the number of types provided controls how many dimensions there are. Each type in the list identifies how the bounds of the corresponding dimension is to be represented. The order of the dimensions is the same order as C++ subscripts declaring a multi-dimensional array – from leftmost to rightmost. Requirements: types in the list be bounds_t<LowerT, UpperT>

The following table provides information on the member types of n_bounds_t

Member Types	Description
`typedef implementation-defined lower_type`	Type of n_index_t<…> returned by method lower()
`typedef implementation-defined upper_type`	Type of n_index_t<…> returned by method upper()

The following table provides information on the members of n_bounds_t.

Member	Description
static constexpr int rank;	Number of dimensions
static constexpr int row_dimension = rank-1;	Index of last dimension considered to be the row
n_bounds_t()	Requirements: Every bounds_t in TypeListT is default constructible. Effects: Construct n_bounds_t, uses default values of each bounds_t in TypeListT for the dimesnion sizes. In general only correctly initialized when every bounds_t has an LowerT and UpperT that is a fixed<NumberT>.
n_bounds_t(const n_bounds_t &a_other)	Effects: Construct n_bounds_t, copying bounds of each dimension from a_other.
template<int DimensionT> auto get() const	Requirements: DimenstionT >=0 and DimensiontT < rank. Effects: Determine the bounds of DimensionT. Returns: In the type declared by the DimensionT position of 0-based TypeListT, the bounds_t of the specified DimensionT
lower_type lower()	Effects: build n_index<…> representing the inclusive lower bounds for all dimensions Returns: n_index[get<0>().lower()] [get<1>().lower()] [get<…>().lower()] [get<row_dimension>().lower()]
upper_type upper()	Effects: build n_index<…> representing the exclusive upper bounds for all dimensions Returns: n_index[get<0>().upper()] [get<1>(). upper ()] [get<…>(). upper ()] [get<row_dimension>().upper()]
template<typename... OtherTypeListT> bool contains(n_bounds_t<OtherTypeListT...> &a_other) const	Requirements: rank of a_other is the same as this instance's. Effects: Determine whether each dimension of the passed n_bounds_t is fully contained within bounds of each dimenson of this object. Returns: get<0>().contains(a_other.get<0>()) && get<1>().contains(a_other.get<1>()) && get<…>().contains(a_other.get<…>()) && get<row_dimension>().contains(a_other.get<row_dimension>())

Member	Description
`template<class... OtherTypeListT>` `bool operator == (const n_bounds_t<OtherTypeListT...> a_other) const`	Requirements: rank of a_other is the same as this instance's. Effects: Compare bounds each of dimension for equality. Only compares numeric values, not the types of each dimension. Returns: true if all dimensions are numerically equal, false otherwise.
`template<class... OtherTypeListT>` `bool operator != (const n_bounds_t<OtherTypeListT...> a_other) const`	Requirements: rank of a_other is the same as this instance's. Effects: Compare bounds of each dimension for inequality. Only compares numeric values, not the types of each dimension. Returns: true if any dimensions are numerically different, false otherwise.
`template<class ...OtherTypeListT>` `auto operator+ (const n_index_t<OtherTypeListT...> a_offset) const`	Requirements: rank of a_other is the same as this instance's. Effects: construct a n_bound_t whose types and bounds value for each dimension are determined by taking the bounds for each dimension and adding the an offset for that dimension from a_offset. Returns: n_bounds[get<0>() + a_offset.get<0>()] [get<1>() + a_offset.get<1>()] [get<…>() + a_offset.get<…>()] [get<row_dimension>() + a_offset.get< row_dimension >()]
`template<int DimensionT>` `auto rightmost_dimensions() const`	Requirements: DimenstionT >=0 and DimensiontT <= rank. Effects: Construct a n_bounds_t with a lower rank by copying the righmost DimensionT values from this instance. Returns: n_bounds[get<rank – DimensionT>()] [get<rank + 1 – DimensionT>()] [get<…>()] [get<row_dimension>()]
`template<class... OtherTypeListT>` `auto overlay_rightmost(const n_bounds_t<OtherTypeListT...> & a_other) const`	Requirements: rank of a_other is <= rank Effects: Construct copy of n_bounds_t where the rightmost dimensions' values are copied from a_other, effectively overlaying a_other ontop of rightmost dimensions of this instance. Returns: n_bounds[get<0>()]

Member	Description
	[get<1 >()] [get<…>()] [get<rank-a_other::rank>()] [a_other.get<0>()] [a_other.get<…>()] [a_other.get<a_other::row_dimension>()]

The following table provides information on the friend functions of n_bounds_t.

Friend Function	Description
`std::ostream& operator << (std::ostream& output_stream, const n_bounds_t & a_bounds_list)`	Effects: append string representation of a_bounds_list values to a_output_stream Returns: reference to a_output_stream for chained calls.

n_bounds_generator

Facilitates simple creation of n_bounds_t objects.

`#include <sdlt/n_bounds.h>`

Syntax

```
template<typename... TypeListT>
class n_bounds_generator;

namespace {
    // Instance of generator object
    n_bounds_generator<> n_bounds;
}
```

Description

The generator object provides recursively constructing operators [] for bounds_t<LowerT, UpperT> values allowing building of a n_bounds_t<…> instance one dimension at a time. Its main purpose is to allow a usage syntax that is similar to C multi-dimensional array definition:

Compare creating two n_bounds_t instances:

```
n_bounds_t<bounds_t<fixed<540>, fixed<1080>>,
           bounds_t<fixed<960>, fixed<1920>>> bounds1(bounds_t<540_fixed,1080_fixed>(),
        bounds_t<960_fixed, 1920_fixed>));

n_bounds_t<bounds_t<int, int>,
           bounds_t<int, int>> bounds2(bounds_t<int, int>(540,960),
        bounds_t<int, int>(960, 1920));
```

and the equivalent instances using the generator objects and factory functions

```
auto bounds1 = n_bounds[bounds(540_fixed, 1080_fixed)]
                       [bounds(960_fixed, 1920_fixed)];
auto bounds2 = n_bounds[bounds(540, 1080)]
                       [bounds(960, 1920)];
```

or alternatively using the operator() with n_index_t and n_extent_t generator objects

```
auto bounds1 = n_bounds(n_index[540_fixed][960_fixed],
                         n_extent[540_fixed][960_fixed]);

auto bounds2 = n_bounds(n_index[540][960],
                        n_extent[540][960]);
```

Class Hierarchy

It is expected that n_bounds_generator<…> not be directly used as a data member or parameter, instead only n_bounds_t<...> from which it is derived. The generator object n_bounds can be automatically downcast any place expecting a n_bounds_t<…>.

The following table provides information on the template arguments for n_bounds_generator

Template Argument	Description
`typename... TypeListT`	Comma separated list of types, where the number of types provided controls how many dimensions there are. Each type in the list identifies how the bounds of the corresponding dimension is to be represented. The order of the dimensions is the same order as C++ subscripts declaring a multi-dimensional array – from leftmost to rightmost. Requirements: types in the list be bounds_t<LowerT, UpperT>

The following table provides information on the types defined as members of n_bounds_generator in addition to those inherited from n_bounds_t

Member Types	Description
`typedef n_bounds_t<TypeListT...> value_type`	Type value that the any chained [] operator calls have produced.

The following table provides information on the members of n_bounds_generator in addition to those inherited from n_bounds_t

Member	Description
`n_bounds_generator()`	Requirements: TypeListT is empty Effects: Construct generator with no bounds specified
`n_bounds_generator(const n_bounds_generator &a_other)`	Effects: Construct generator copying any bounds values from a_other
`template<typename LowerT, typename UpperT> auto operator [] (const bounds_t<LowerT, UpperT> & a_bounds) const`	Effects: build a n_bounds_generator<…> with additional rightmost bounds_t<LowerT, UpperT> based dimension. Returns: n_bounds_generator<TypeListT..., bounds_t< LowerT, UpperT >>
`template<class... IndexTypeListT, class... ExtentTypeListT> auto operator () ( const n_index_t<IndexTypeListT...> &`	Requirements: rank of a_indices is same as rank of a_extents and TypeListT be empty

Member	Description
`a_indices,` `const n_extent_t<ExtentTypeListT...> & a_extents) const`	Effects: build a n_bounds_generator<…> where n-lower bounds are specified by a_indices, and n-upper bounds are calculated by adding a_extents to a_indices Returns: n_bounds[bounds(a_indices.get<0>(), a_indices.get<0>() + a_extents.get<0>())] [bounds(a_indices.get<1>(), a_indices.get<1>() + a_extents.get<1>())] [bounds(a_indices.get<…>(), a_indices.get<…>() + a_extents.get<…>())] [bounds(a_indices.get<row_dimension>(), a_indices.get< row_dimension >() + a_extents.get< row_dimension >())]
`value_type value() const`	Returns: n_bounds_t<…> with the correct types and values of the multi-dimensional bounds aggregated by the generator.

bounds_d Template Function

Provides a consistent way to determine the bounds of a dimension for a multi-dimensional object. `#include <sdlt/n_extent.h>`

Syntax

```
template<int DimensionT, typename ObjT>
auto bounds_d(const ObjT &a_obj)
```

Description

Consistent way to determine the bounds of a dimension for a multi-dimensional object. Can avoid extracting an entire n_bounds_t<…> when only the extent of a single dimension is needed.

Template Argument	Description
`int DimensionT`	0 based index starting at the leftmost dimension indicating which n-dimensions to query the bounds of. Requirements: DimensionT >=0 and DimensionT < ObjT::rank
`typename ObjT`	The type of n-dimensional object from which to retrieve the extent. Requirements: ObtT is one of: n_container<…> n_bounds_t<…> n_bounds_generator<…> n_container<…>::accessor

Template Argument	Description
	n_container<…>::const_accessor or any sectioned or translated accessor.

Returns:

The correctly typed bounds_t<LowerT, UpperT> corresponding to the requested DimensionT of a_obj.

Example:

```
template <typename VolumeT>
void foo(const VolumeT & a_volume)
{
    auto bounds_z = bounds_d<0>(volume);
    auto bounds_y = bounds_d<1>(volume);
    auto bounds_x = bounds_d<2>(volume);
    for(auto z : bounds_z)
        for(auto y : bounds_y)
            for(auto x : bounds_x) {
                // …
            }
}
```

Accessors

soa1d_container::accessor and aos1d_container::accessor

Lightweight object provides efficient array subscript [] access to the read or write elements from inside a soa1d_container or aos1d_container. `#include <sdlt/soa1d_container.h>` *and* `#include <sdlt/aos1d_container.h>`

Syntax

```
template <typename OffsetT> soa1d_container::accessor;
template <typename OffsetT> aos1d_container::accessor;
```

Arguments

`typename OffsetT`	The type offset that will be applied to each operator[] call determined by the type of offset passed into `soa1d_container::access(offset)`/ `aos1d_container::access(offset)` which constructs an accessor.

Description

`accessor` provides [] operator that returns a proxy object representing an Element inside the Container that can export or import the Primitive's data. Can re-access with an offset to create a new *accessor* that when accessed at [0] will really be accessing at index corresponding to the embedded offset. Lightweight and meant to be passed by value into functions or lambda closures. Use accessors in place of pointers to access the logical array data.

Member	Description
`accessor();`	Default Constructible

Member	Description
`accessor(const accessor &);`	Copy Constructible
`accessor & operator = (const accessor &);`	Copy Assignable
`const int & get_size_d1() const;`	Returns: Number of elements in the container.
`auto operator [] (int index_d1) const`	Returns: proxy Element representing element *at index_d1* in the container..
`template<typename IndexT_D1> auto operator [] (const IndexT_D1 index_d1);`	When: IndexT_D1 is one of the SDLT defined or generated Index types, Returns: proxy Element representing element at *index_d1* in the container.
`auto reaccess(const int offset) const;`	Returns: *accessor* with an integer-based embedded index *offset*.
`template<int IndexAlignmentT> auto reaccess(aligned_offset<IndexAlignmentT> offset) const;`	Returns: *accessor* with an `aligned_offset<IndexAlignmentT>` based embedded index *offset*.
`template<int fixed_offsetT> auto reaccess(fixed_offset<fixed_offsetT>) const;`	Returns: *accessor* with a `fixed_offset<OffsetT>` based embedded index *offset*.

soa1d_container::const_accessor and aos1d_container::const_accessor

Lightweight object provides efficient array subscript [] access to the read elements from inside a soa1d_container or aos1d_container. `#include <sdlt/soa1d_container.h>` *and* `#include <sdlt/aos1d_container.h>`

Syntax

```
template <typename OffsetT> soa1d_container::const_accessor;
template <typename OffsetT> aos1d_container::const_accessor;
```

Arguments

`typename OffsetT`	The type offset that embedded offset that will be applied to each operator[] call

Description

`const_accessor` provides [] operator that returns a proxy object representing a const Element inside the Container that can export the Primitive's data. Can re-access with an offset to create a new *const_accessor* that when accessed at [0] will really be accessing at index corresponding to the embedded offset. Lightweight and meant to be passed by value into functions or lambda closures. Use *const_accessors* in place of const pointers to access the logical array data.

Member	Description
`const_accessor();`	Default Constructible

Member	Description
`const_accessor(const const_accessor &);`	Copy Constructible
`const_accessor & operator = (const const_accessor &);`	Copy Assignable
`const int & get_size_d1() const;`	Returns: Number of elements in the container.
`auto operator [] (int index_d1) const`	Returns: proxy ConstElement representing element at*index_d1* in the container..
`template<typename IndexT_D1> auto operator [] (const IndexT_D1 index_d1);`	When: IndexT_D1 is one of the SDLT defined or generated Index types. Returns: proxy ConstElement representing element at *index_d1* in the container.
`auto reaccess(const int offset) const;`	Returns: *const_accessor* with an integer-based embedded index *offset*.
`template<int IndexAlignmentT> auto reaccess(aligned_offset<IndexAlignmentT> offset) const;`	Returns: *const_accessor* with an `aligned_offset<IndexAlignmentT>` based embedded index *offset*.
`template<int fixed_offsetT> auto reaccess(fixed_offset<fixed_offsetT>) const;`	Returns: *const_accessor* with a `fixed_offset<OffsetT>` based embedded index *offset*.

Accessor Concept

Accessor and const_accessor objects obtained via `n_container::access()` *and* `n_container::const_access()` *provide access to read from or write to cells inside an* `n_container`*.*

Syntax

The following methods return objects meeting the requirements of the accessor concept.

```
auto n_container::access();
auto n_container::const_access();
auto accessor_concept::section(n_bounds_t<…>);
auto accessor_concept::translated_to(n_index_t<…>);
auto accessor_concept::translated_to_zero();
```

Description

Accessor objects provide read/write access to individual cells of an n-dimensional container. Index values passed to a sequence of array subscript operator calls will produce a proxy concept that can import to or export the primitive data the corresponding cell inside the container.

```
auto image = make_n_container<MyStruct, layout::soa>(n_extent[128][256]);
auto acc = image.access();
MyStruct in_value(100.0f, 200.0f, 300.0f);

acc[64][128] = in_value;
```

```
MyStruct out_value = acc[64][128];

assert(out_value == in_value);
```

Accessors also know their valid iteration space, which can queried using the template function bound_d<int DimensionT>(accessor).

```
assert(bounds_d<0>(acc) == bounds(0_fixed,128));
assert(bounds_d<1>(acc) == bounds(0_fixed,256));
```

An accessor may have a non-zero index space if it has a translation embedded into it, `bounds_d` will reflect any such translation.

```
auto shifted_acc = acc.translated_to(n_index[1000][2000]);
assert(bounds_d<0>(shifted_acc) == bounds(1000,1128));
assert(bounds_d<1>(shifted_acc) == bounds(2000,2256));
```

This is useful to have a smaller sized container participate in a calculation over a portion of a larger index space, simplifying programming as the same index variable can be used, and the accessor takes care of applying the necessary translation. An accessor may represent a subsection over the original extents, bounds_d will identify the valid iteration space for that accessor.

```
auto subsection_acc = a.section(n_bounds[bounds(64,96)][bounds(128,160)]);
assert(bounds_d<0>(subsection_acc) == bounds(64, 96));
assert(bounds_d<1>(subsection_acc) == bounds(128, 160);
```

It can also be useful to have subsections be translated back to start their iteration space at 0. For efficiency, the translated_to_zero() method is provided to create an accessor shifted back to zero.

```
auto zb_sub_acc = a.section( n_bounds[bounds(64, 96)][bounds(128, 160)] ).translated_to_zero();
assert(bounds_d<0>(zb_sub_acc) == bounds(0, 32));
assert(bounds_d<1>(zb_sub_acc) == bounds(0, 32));
```

If fewer array subscript calls applied to an accessor than its rank, the result is another accessor of a lower rank. This can be useful to obtain accessors suitable to pass to code expecting lower rank accessors. Such as a obtaining a 3d accessor from a 4d container by specifying only a single index via array subscript. This has the effect of embedding the index value of the dimension inside accessor. When the final dimension is sliced, the result is a proxy object to the cell inside the container corresponding to the embedded index values inside the sliced accessors

```
auto image4d = make_n_container<MyStruct, layout::soa>(n_extent[10][20][128][256]);

MyStruct in_value(100.0f, 200.0f, 300.0f);
auto acc4d = image4d.access();
auto acc3d = acc4d[5];
auto acc2d = acc3d[10];
auto acc1d = acc2d[64];
acc1d[128] = in_value;
MyStruct out_value = acc4d[5][10][64][128];
assert(out_value == in_value);
```

The following table provides information on the requirements of the accessor concept.

Pseudo-Signature	Description
`typedef PrimitiveT primitive_type;`	Data type inside the cells of the container.
`static constexpr int rank;`	Number of free dimensions of accessor

Pseudo-Signature	Description
accessor_concept(const accessor_concept &a_other)	Effects: constructs a copy of another accessor of the exact same type
template<typename IndexT> element_concept operator[] (const IndexT a_index) const	**Requirements:** rank == 1 and IndexT is one of: int, aligned<AlignmentT>, fixed<NumberT>, linear_index, or simd_index<LaneCountT> **Effects:** When only 1 free dimension is left, the operator[] will construct an element_concept which is the proxy to the cell inside the container. If this accessor was obtained with const_access(), then the proxy will provide read only interface to the cell's data. **Returns:** The proxy object to cell inside the container corresponding to the position identified by the a_index along with any embedded index values for other dimensions
template<typename IndexT> accessor_concept operator[] (const IndexT a_index) const	**Requirements:** rank > 1 and IndexT is one of: int, aligned<AlignmentT>, fixed<NumberT>, linear_index, or simd_index<LaneCountT> **Effects:** When 2 or more free dimensions are left, the operator[] will construct another accessor_concept of lower rank embeding a_index inside of it, effectively fixing that dimension's index value for any accesses made through the returned accessor_concept. **Returns:** The accessor_concept of lower rank (one less free dimension).
template<int DimensionT> auto bounds_d() const	**Requirements:** DimensionT >=0 and DimensionT < rank **Effects:** Determine the bounds of a free dimension using DimensionT as a 0 based index starting at the leftmost dimension. **Returns:** bounds_t of the DimensionT
auto bounds_d*XX*() const where XX is 0-19	**Requirements:** XX >=0 and XX < rank and XX < 20 **Effects:** Non templated methods to determine the bounds of a free dimension using XX as a 0 based index starting at the leftmost dimension. **Returns:** bounds_t of the XX dimension
template<int DimensionT> auto extent_d() const	**Requirements:** DimensionT >=0 and DimensionT < rank **Effects:** Determine the extent of a free dimension using DimensionT as a 0 based index starting at the leftmost dimension. Returns: extent of the DimensionT

Pseudo-Signature	Description
`auto extent_dXX() const` `where XX is 0-19`	**Requirements:** XX >=0 and XX < rank and XX < 20 **Effects:** Non templated methods to determine the extent of a free dimension using XX as a 0 based index starting at the leftmost dimension. Returns: extent of the XX dimension

`template<typename ...IndexListT>`
`accessor_concept translated_to(`
`    n_index_t<IndexListT...> a_n_index) const`
	Requirements: a_n_index has same rank as the accessor
	Effects: construct an accessor_concept with an embedded translation such that accessing a_n_index will corresponds back to the current lower bounds. Easy way to think of it is that current iteration space is translated to a_n_index space.
	Returns: accessor_concept whose bounds have the same extents, but whose lower bounds start at the supplied a_n_index

`template<typename ...IndexListT>` `accessor_concept translated_to_zero() const`	**Effects:** construct an accessor_concept with an embedded translation such that accessing [0] index for all dimensions will corresponds back to the current lower bounds. Easy way to think of it is that current iteration space is translated to [0] for all free dimensions. **Returns:** accessor_concept whose bounds have the same extents, but whose lower bounds start [0]…[0]

`template<typename ...BoundsTypeListT>`
`    auto`
`    section(const`
`n_bounds_t<BoundsTypeListT...> &a_n_bounds)`
`const`
	Requirements: a_n_bounds has same rank as the accessor and a_n_bounds is contained by the accessors current bounds.
	Effects: construct an accessor_concept with using the supplied a_n_bounds to represent its valid iteration space. Because a_n_bounds must be contained within the existing bounds, we are effictively creating an accessor over a section of the container. Easy way to think of it is that current bounds are being restricted to a_n_bounds. Note: can be useful to chain a call `translated_to_zero()` on to the return value.
	Returns:`accessor_concept` whose bounds are set to the supplied a_n_bounds

Proxy Objects

*accessor*s can't return a reference to the Primitive because its memory layout is abstracted. Instead a Proxy object is returned. That Proxy supports importing or exporting data to and from the Container. The actual type of Proxy objects is an implementation detail, but they all support the same public interface which we will document.

Each *accessor* [index] operator returns a Proxy object.

Each *const_accessor* [index] operator returns a ConstProxy object.

The Proxy objects provide a Data Member Interface where for each data member of *value_type* they are representing, a member access method is defined which returns a new Proxy or ConstProxy representing just that data member. Users can drill down through a complex data structure to get a Proxy representing the exact data member they need versus importing and exporting the entire Primitive value.

Proxy objects also overload the following operators if the underlying *value_type* supports the operator:

==, !=, <, >, <=, >=, +, -, *, /, %, &&, ||, &, |, ^, ~, *, +, -, !, +=, -=, *=, /=, %=, >>=, <<=, &=, |=, ^=, ++, --

Proxy

Proxy object provides access to a specific Primitive, Primitive data member, or nested data member within a Primitive for an element in a container.

Description

accessor [index] or a Proxy object's Data Member Interfaces return Proxy objects. That Proxy object represents the Primitive, Primitive data member, or nested data member within a Primitive for an element in a container. The Proxy object has the following features:

- A value_type can be exported or imported from the Proxy.
  - Conversion operator is used to export the value_type
  - Alternatively the Proxy can be passed to the function `unproxy` to export a `value_type`
  - Assignment operator = is used to import value_type into the Proxy
- Overloads the following operators if the underlying value_type supports the operator
  - ==, !=, <, >, <=, >=, +, -, *, /, %, &&, ||, &, |, ^, ~, *, +, -, !, +=, -=, *=, /=, %=, >>=, <<=, &=, |=, ^=, ++, --
  - When an operator is called the following occurs:
    - value_type is exported
    - The operator applied to the exported value
    - If the operator was an assignment, the result is imported back into the Member and returns the proxy
    - Otherwise a result is returned.
- Data Member Interface.
  - For each data member of value_type
    - A member access method is defined which returns a Member proxy representing just that member.

Member Type	Description
`typedef implementation-defined value_type`	The type of the data the Proxy is representing

Member	Description
`operator value_type const () const;`	Returns: exports a copy of the Proxy's value. NOTE: constant return value prevents rvalue assignment for structs offering some protection against code that expected a modifiable reference.
`const value_type &` `operator = (const value_type &a_value);`	Imports a_value into container at the position the Proxy is representing. Returns: the same constant value_type it was passed.

Member	Description
	NOTE: This behavior is different from traditional assignment operators that return *this. Choice was to enable efficient chaining of assignment operators versus returning a Proxy which would have to export the value it had just imported.
`Proxy & operator = (const Proxy &other);`	Exports value from the other Proxy and imports it. Returns: A reference to this Proxy obect.
`auto name_of_values_data_member_1()const;`	Returns: Proxy instance representing the 1st data member of the value_type NOTE: actual method name is the name of the value_type's 1st data member
`auto name_of_values_data_member_2()const;`	Returns: Proxy instance representing the 2nd data member of the value_type. NOTE: actual method name is the name of the value_type's 2nd data member.
`auto name_of_values_data_member_...()const;`	Returns: Proxy instance representing the ...th data member of the value_type. NOTE: actual method name is the name of the value_type's …th data member.
`auto name_of_values_data_member_N()const;`	Returns: Proxy instance representing the Nth data member of the value_type. NOTE: actual method name is the name of the value_type's Nth data member

ConstProxy

ConstProxy object provides access to a specific constant primitive, primitive data member, or nested data member within a primitive for an element in a container.

Description

const_accessor [index] or a ConstProxy object's Data Member Interfaces return ConstProxy objects. That ConstProxy object represents the constant primitive, primitive data member, or nested data member within a primitive for an element in a container. The ConstProxy object has the following features:

- A value_type can be exported or imported from the ConstProxy.
  - Conversion operator is used to export the value_type
  - Alternatively the ConstProxy can be passed to the function `unproxy` to export a `value_type`
- Overloads the following operators if the underlying value_type supports the operator
  - ==, !=, <, >, <=, >=, +, -, *, /, %, &&, ||, &, |, ^, ~, *, +, -, !
  - When an operator is called the following occurs:
    - value_type is exported
    - The operator applied to the exported value
    - returns the result.
- Data Member Interface.
  - For each data member of value_type

- A member access method is defined which returns a Member ConstProxy representing just that member.

Member Type	Description
`typedef implementation-defined value_type`	The type of the data the ConstProxy is representing

Member	Description
`operator value_type const () const;`	Returns: exports a copy of the ConstProxy's value. NOTE: constant return value prevents rvalue assignment for structs offering some protection against code that expected a modifiable reference.
`auto name_of_values_data_member_1()const;`	Returns: ConstProxy instance representing the 1st data member of the value_type NOTE: actual method name is the name of the value_type's 1st data member
`auto name_of_values_data_member_2()const;`	Returns: ConstProxy instance representing the 2nd data member of the value_type. NOTE: actual method name is the name of the value_type's 2nd data member.
`auto name_of_values_data_member_...()const;`	Returns: ConstProxy instance representing the ...th data member of the value_type. NOTE: actual method name is the name of the value_type's ...th data member.
`auto name_of_values_data_member_N()const;`	Returns: ConstProxy instance representing the Nth data member of the value_type. NOTE: actual method name is the name of the value_type's Nth data member

Number Representation

When specifying extents, positions inside of, or bounds of a container, numeric values can be represented three different ways: `fixed`, `aligned`, and `int`. `Fixed` is most precise and `int` is least precise. It is advised to use as precise specification as possible. The compiler may optimize better with more information.

Fixed

Represent a numerical constant whose value specified at compile time.

```
template <int NumberT> class fixed;
```

If offsets applied to index values inside a SIMD loop are known at compile time, then the compiler can use that information. For example, to maintain aligned access, if boundary is fixed and known to be aligned when accessing underlying data layout. When multiple accesses are happening near each other, the compiler will have the opportunity to detect which accesses occur in the same cache lines and potentially avoid prefetching the same cache line repeatedly. Additionally, if the start of an iteration space is known at compile time, if it's a multiple of the SIMD lane count, the compiler could skip generating a peel loop. Whenever possible, `fixed` values should be used over `aligned` or arbitrary integer values.

Although `std::integral_constant<int>` provides the same functionality, the library defines own type to provide overloaded operators and avoid collisions with any other code's interactions with `std::integral_constant<int>`.

The following table provides information about the template arguments for `fixed`.

Template Argument	Description
`int Number T`	The numerical value the fixed will represent.

The following table provides information about the members of `fixed`.

Member	Description
`static constexpr int value = NumberT`	The numerical value known at compile-time.
`constexpr operator value_type() const`	**Returns:** The numerical value
`constexpr value_type operator()() const;`	**Returns:** The numerical value

Constant expression arithmetic operators +,- (both unary and binary), * and / are defined for type `sdlt::fixed<>` and will be evaluated at compile-time.

The suffix `_fixed` is a C++11 user-defined equivalent literal. For example, `1080_fixed` is equivalent to `fixed<1080>`. Consider the readability of the two samples below.

```
foo3d(fixed<1080>(), fixed<1920>());
```

versus

```
foo3d(1080_fixed, 1920_fixed);
```

> **NOTE** The `sdlt::fixed<NumberT>` type supersedes the deprecated `sdlt::fixed_offset<OffsetT>` type found in SDLT v1. It is strongly advised to use `sdlt::fixed<NumberT>`. However, in this release, a template alias is provided mapping `sdlt::fixed_offset<OffsetT>` onto `sdlt::fixed<NumberT>`.

Aligned

Represent integer value known at compile time to be a multiple of an `IndexAlignment`.

```
template <int IndexAlignmentT> class aligned;
```

If you can tell the compiler that you know that an integer will be a multiple of known value, then, when combined with a loop index inside a SIMD loop, the compiler can use that information to maintain aligned access when accessing underlying data layout.

Internally, the integer value is converted to a block count, where:

```
block_count = value/IndexAlignmentT;
```

Overloaded math operations can then use that aligned block count as needed. The value() is represented by `AlignmentT*block_count` allowing the compiler to prove that the value() is a multiple of `AlignmentT`, which can utilize alignment optimizations.

The following table provides information about the template arguments for `aligned`.

Template Argument	Description
`int IndexAlignmentT`	The alignment the user is stating that the number is a multiple of. `IndexAlignmentT` must be a power of two.

The following table provides information about the types defined as members of aligned.

Member Type	Description
typedef int value_type	The type of the numerical value.
typedef int block_type	The type of the block_count.

The following table provides information about the members of aligned.

Member	Description
static const int index_alignment	The IndexAlignmentT value.
aligned()	Constructs empty (uninitialized) object
explicit aligned(value_type)	Constructs computing block_count=a_value/ IndexAlignmentT.
aligned(const aligned& a_other)	Constructs copying block_count from a_other. a_other must have same IndexAlignmentT.
template<int OtherAlignment> explicit aligned(const aligned& other)	Constructs computing block_count optimized by avoiding computing other.value(). Must have IndexAlignmentT of a_other < IndexAlignmentT and other.value() be multiple of IndexAlignmentT.
template<int OtherAlignment> aligned(const aligned& other)	Constructs computing block_count with a multiply instead of divide. Must have IndexAlignmentT of a_other > IndexAlignmentT
static aligned from_block_count(block_type block_count)	Creates an instance of aligned avoiding any math by directly using supplied block_count
value_type value() const	Computes the value represented by the aligned. **Returns:** aligned_block_count()*IndexAlignmentT
operator value_type()	Conversion to int. **Returns:** value()
block_type aligned_block_count() const	Conversion to int. **Returns:** The block count

The following operations are supported for the aligned type.

Operation	Description
operator *(int), commutative	Scale value. Returns: aligned<IndexAlignmentT >
operator *(fixed<V>), commutative	Scales IndexAlignment by 2^M and value by K. Must have V=2^M*K (V is a multiple of a power of 2). **Returns:** aligned<IndexAlignmentT*(2^M)>

Operation	Description
operator *(aligned<OtherAl>)	Scales IndexAlignment by OtherAl and block_count by argument. **Returns:** aligned<IndexAlignmentT*OtherAl>
int operator/(fixed<IndexAlignmentT>)	**Returns:** aligned_block_count()
int operator/(fixed<-IndexAlignmentT>)	**Returns:** -aligned_block_count();
int operator/(fixed<V>)	Must have abs(V)>IndexAlignmentT && IndexAlignmentT%V==0. **Returns:** aligned_block_count()/(V/ IndexAlignmentT)
int operator/(fixed<V>)	Must have abs(V) < IndexAlignmentT && V %IndexAlignmentT==0 **Returns:** aligned_block_count()*(IndexAlignmentT/V)
aligned operator -()	**Returns:** Same type aligned for negated value.
aligned operator -(const aligned &) const	**Returns:** Same type aligned for value of difference.
template<int OtherAl> aligned<?> operator -(const aligned<OtherAl>&) const	Difference with other alignment. Behavior and returned alignment type depend on relation between alignments of operands. **Returns:** Value for difference as lower of incoming alignments
template<int V> aligned<?> operator -(const fixed<V> &) const	Difference with fixed value. Behavior and returned alignment type depend on relation between alignments of aligned<> operand and the value of V. **Returns:** Adjusted aligned value of a difference
aligned operator +(const aligned &)const	**Returns:** Same type aligned for value of sum
template<int OtherAl> aligned<?> operator +(const aligned<OtherAl>&) const	Sum with other alignment. Behavior and returned alignment type depend on relation between alignments of operands. **Returns:** Value for sum as lower of incoming alignments
template<int V> aligned<?> operator +(const fixed<V> &) const	Sum with fixed value. Behavior and returned alignment type depend on relation between alignments of aligned<> operand and the value of V. **Returns:** Adjusted aligned value of a sum.

Operation	Description
`template<int OtherAl>` `aligned operator +=(const aligned<OtherAl> &) const`	Increments value for the aligned object if `IndexAlignmentT` is compatible with `OtherAl` **Returns:** Aligned with incremented value.
`template<int OtherAl>` `aligned operator -=(const aligned<OtherAl> &) const`	Decrements value for the aligned object if `IndexAlignmentT` is compatible with `OtherAl` **Returns:** Same type aligned with decremented value.
`template<int OtherAl>` `aligned operator *=(const aligned<OtherAl> &) const`	Multiplies value for the aligned object if `IndexAlignmentT` is compatible with `OtherAl`. **Returns:** Same type aligned with multiplied value.
`template<int OtherAl>` `aligned operator /=(const aligned<OtherAl> &) const`	Divides value for the aligned object if `IndexAlignmentT` is compatible with `OtherAl` **Returns:** Same type aligned with divided value.

NOTE The `sdlt::aligned<>` type supersedes the deprecated `sdlt::aligned_offset<>` type found in SDLT v1. It is strongly advised to use `sdlt::aligned<>`, however in this release a template alias is provided mapping `sdlt::aligned_offset<>` onto `sdlt::aligned<>`.

int

Represents an arbitrary integer value. In interfaces where fixed<> and aligned<> values supported you may also use plain old integer value. It provides least information among these three and so least facilitates compiler optimizations.

aligned_offset

Represent an integer based offset whose value is a multiple of an IndexAlignment specified at compile time. `#include <sdlt/aligned_offset.h>`

Syntax

```
template<int IndexAlignmentT>
class aligned_offset;
```

Arguments

`int IndexAlignmentT`	The index alignment the user is stating that the offset have.

Description

aligned_offset is a deprecated feature.

If we can tell the compiler that we know an offset will be a multiple of known value, then when combined with a loop index inside a SIMD loop, the compiler can use that information to maintain aligned access when accessing underlying data layout.

Internally, the offset value is converted to a block count.

```
Block Count = offsetValue/IndexAlignmentT;
```

Indices can then use that aligned block count as needed.

Member	Description
`static const int IndexAlignment = IndexAlignmentT;`	The alignment the offset is a multiple of
`explicit aligned_offset(const int offset)`	Construct instance based on offset
`static aligned_offset from_block_count(int aligned_block_count);`	Returns: Instance based on aligned_block_count, where the offset value = IndexAlignment*aligned_block_count
`int aligned_block_count() const;`	Returns: number of blocks of IndexAlignment it takes to represent the offset value.
`int value() const;`	Returns: offset value

fixed_offset

Represent an integer based offset whose value specified at compile time. `#include <sdlt/fixed_offset.h>`

Syntax

```
template <int OffsetT> fixed_offset;
```

Arguments

`int OffsetT`	The value the fixed_offset will represent

Description

fixed_offset is a deprecated feature.

If we can tell the compiler that we know an offset at compile time, then when combined with a loop index inside a SIMD loop, the compiler can use that information to maintain aligned access (should the offset be aligned) when accessing underlying data layout. When multiple accesses are happening near each other, the compiler will have the opportunity to detect which accesses occur in the same cache lines and potentially avoid prefetching the same cache line repeatedly. Whenever possible, a fixed_offset should be used over an aligned_offset or integer based offset.

Member	Description
`static constexpr int value = OffsetT`	The offset value known at compile

Indexes

soa1d_container's and aos1d_container's accessors [] operator can accept an integer based loop index. However if any modifications were applied to that loop index, the fact that it's a loop index may be lost by the compiler as it is handled before being passed to the [] operator.

To avoid this situation, SDLT provides classes to wrap loop indexes that capture multiple additions or subtractions of offsets (see the Offsets section). The resulting index can be passed to [] and preserve the original loop index and track any arithmetic with Offsets to be applied to underlying data layout.

It is common for stencil based algorithms to need to apply offsets during data access.

For a regular linear loop, use linear_index to wrap your loop index.

linear_index

Wraps an integer-based loop index that is iterating linearly through an iteration space. `#include <sdlt/linear_index.h>`

Syntax

```
class linear_index;
```

Description

Inside of a linear loop, wrap the loop index with a `linear_index` to allow addition or subtraction of offsets.

Member	Description
`explicit linear_index(int an_index);`	Construct instance from a loop index
`int value() const;`	Returns the original loop index

n_index_t

Variadic template class n_index_t describes a position inside of the N-dimensional container. Specifically, the number of dimensions and the of index value of each.

Syntax

```
template<typename... TypeListT>
class n_index_t
```

Description

`n_index_t` represents a position inside an n-dimensional space as a sequence of index value for each dimension. The index of each dimension can be represented by different types. This flexibility allows the same interface to be used to declare `n_index_t` with indices that are fully known at compile time with `fixed<int NumberT>`, or to be only known at runtime with `int`, or only known at runtime but with a guarantee will be a multiple of an alignment with `aligned<int Alignment>`. For more details, see the Number representation section.

Objects of this class may be used to identify a cell in a container, describe the inclusive lower bounds for `n_bounds()`, n-dimensional position for accessor's *translated_to()*.

The following table provides information about the template arguments for `n_index_t`.

Template Argument	Description
`typename... TypeListT`	Comma separated list of types, where the number of types provided controls how many dimensions there are. Each type in the list identifies how the index of the corresponding dimension is to be represented. The order of the dimensions is the same order as C++ subscripts declaring a multi-dimensional array, from leftmost to rightmost. **Requirements**: Type must be `int`, or `fixed<NumberT>`, or `aligned<AlignmentT>`.

The following table provides information about the members of `n_index_t`

Member	Description
`static constexpr int rank;`	Number of dimensions.
`static constexpr int row_dimension = rank-1;`	Index of last dimension, *row.*
`n_index_t()`	Default constructor. Uses default values for extent types. **Requirements:** Every type in TypeListT is default constructible. **Effects:** Construct n_index_t, uses default values of each type in TypeListT for the dimesnion sizes. In general only correctly initialized when every type is a fixed<NumberT>.
`n_index_t(const n_extent_t &a_other)`	Copy constructor. **Effects:** Construct n_index_t, copying index value of each dimension from a_other.
`explicit n_index_t(const TypeListT & … a_values)`	**Returns:** The last extent in its native type **Effects:** Construct n_index_t, initializing each dimension with the corresponding value from the list of *a_values* passed as an argument. In use, *a_values* is a comma separate list of values whose length and types are defined by TypeListT.
`template<int DimensionT>` `auto get() const`	**Requirements:** DimenstionT >=0 and DimensiontT < rank. **Effects:** Determine the index value of DimensionT. **Returns:** In the type declared by the DimensionT position of 0-based TypeListT, the index value of the specified *DimensionT*
`n_index_t operator +() const`	**Effects:** Determine the positive unary value of each dimension's index, effectively no operation is performed **Returns:** Copy of the current instance.
`auto operator -() const`	**Effects:** Determine the negative unary value of each dimension's index **Returns:** n_index[-get<0>()] [-get<1>()] [-get<…>()] [-get<row_dimension>()]

`template<class... OtherTypeListT>`
`auto operator +(`
`   const n_index_t<OtherTypeListT...> & a_other) const`
	Requirements: Rank of a_other is the same as this instance's.
	
	Effects: Build n_index_t whose values are the result of adding the index value for each dimension with those of a_other

Member	Description
	Returns: n_index[get<0>() + a_other.get<0>()] [get<1>() + a_other.get<1>()] [get<…>() + a_other.get<…>()] [get<row_dimension>() + a_other.get<row_dimension>()]

`template<class... OtherTypeListT>`
`auto operator -(`
`   const n_index_t<OtherTypeListT...> &`
`a_other) const`
	Requirements: Rank of a_other is the same as this instance's.
	Effects: Build n_index_t whose values are the result of subtracting the index value for each dimension of a_other with this instance's.
	Returns: n_index[get<0>() - a_other.get<0>()]
	[get<1>() - a_other.get<1>()]
	[get<…>() - a_other.get<…>()]
	[get<row_dimension>() -
	a_other.get<row_dimension>()]

`template<class... OtherTypeListT>`
`bool operator == (const`
`n_index_t<OtherTypeListT...> a_other) const`
	Requirements: Rank of a_other is the same as this instance's.
	Effects: Compare index of each dimension for equality. Only compares numeric values, not the types of each dimension.
	Returns:*true* if all dimensions are numerically equal, *false* otherwise.

`template<class... OtherTypeListT>`
`bool operator != (const`
`n_index_t<OtherTypeListT...> a_other) const`
	Requirements: Rank of a_other is the same as this instance's.
	Effects: Compare index of each dimension for inequality. Only compares numeric values, not the types of each dimension.
	Returns: *true* if any dimensions are numerically different, *false* otherwise.

`template<int DimensionT>` `auto rightmost_dimensions() const`	**Requirements:** DimenstionT >=0 and DimensiontT <= rank. **Effects:** Construct a n_index_t with a lower rank by copying the righmost DimensionT values from this instance. **Returns:** n_index[get<rank - DimensionT>()] [get<rank + 1 - DimensionT>()] [get<…>()] [get<row_dimension>()]

Member	Description
`template<class... OtherTypeListT> auto overlay_rightmost(const n_index_t<OtherTypeListT...> & a_other) const`	**Requirements:** rank of a_other is <= rank **Effects:** Construct copy of n_index_t where the rightmost dimensions' values are copied from a_other, effectively overlaying a_other ontop of rightmost dimensions of this instance. **Returns**: n_index[get<0>()] [get<1 >()] [get<...>()] [get<rank-a_other::rank>()] [a_other.get<0>()] [a_other.get<...>()] [a_other.get<a_other::row_dimension>()]

The following table provides information about the friend functions of `n_index_t`

Friend Function	Description
`std::ostream& operator << (std::ostream& output_stream, const n_index_t & a_indices)`	**Effects:** Append string representation of a_indices' values to a_output_stream. **Returns:** Reference to a_output_stream for chained calls.

n_index_generator

To facilitate simpler creation of `n_index_t` *objects, the generator object* `n_index` *is provided.*

Syntax

```
template<typename... TypeListT>
class n_index_generator;

namespace {
    // Instance of generator object
    n_index_generator<> n_index;
}
```

Description

The generator object provides recursively constructing operators [] for `fixed<>`, `aligned<>`, and `integer` values allowing building of a `n_index_t<…>` instance one dimension at a time. Its main purpose is to allow a usage syntax that is similar to C multi-dimensional array definition.

Compare the following examples, instantiating three `n_index_t` instances, and using the generator object to instantiate equivalent instances.

```
n_index_t<int, int> idx1(row, col);
n_index_t<int, aligned<16>> idx2(row, aligned<16>(col));
n_index_t<fixed<540>, fixed<960>> idx3(540_fixed, 960_fixed);
```

```
auto idx1 = n_index[row][col];
auto idx2 = n_index[row][aligned<16>(col)];
auto idx3 = n_index[540_fixed][960_fixed];
```

Class Hierarchy

It is expected that `n_index_generator` < … > not be directly used as a data member or parameter, instead only `n_index_t` <…> from which it is derived. The generator object `n_index` can be automatically downcast any place expecting an `n_index_t<…>` .

The following table provides the template arguments for `n_index_generator`

Template Argument	Description
`typename... TypeListT`	Comma separated list of types, where the number of types provided controls how many dimensions the generator currently represents. Each type in the list identifies how the size of the corresponding dimension is to be represented. The order of the dimensions is the same order as C++ subscripts declaring a multi-dimensional array – from leftmost to rightmost. **Requirements**: Type is `int`, `fixed<NumberT>`, or `aligned<AlignmentT>`.

The following table provides information on the types defined as members of `n_index_generator` in addition to those inherited from `n_index_t`.

Member Type	Description
`typedef n_index_t<TypeListT...> value_type`	Type value that the any chained [] operator calls have produced.

The following table provides information on the members of `n_index_generator` in addition to those inherited from `n_index_t`

Member	Description
`n_index_generator ()`	**Requirements:** TypeListT is empty. **Effects:** Construct generator with no indices specified.
`n_index_generator (const n_index_generator &a_other)`	**Effects:** Construct generator copying any index values from a_other
`n_index_generator<TypeListT..., int> operator [] (int a_index) const`	**Requirements:** a_size >= 0. **Returns:** n_index_generator<…> with additional rightmost integer based index.
`n_index_generator<TypeListT..., fixed<NumberT>> operator [] (fixed<NumberT> a_index) const`	**Requirements:** a_size >= 0. **Returns:** n_index_generator<…> with additional rightmost fixed<NumberT> index.
`n_index_generator<TypeListT..., aligned<AlignmentT>> operator [] (aligned<AlignmentT> a_index)`	**Requirements:** a_size >= 0 **Returns:** n_index_generator<…> with additional rightmost aligned<AlignmentT> based index.
`value_type value() const`	**Returns:** n_extent_t<…> with the correct types and values of the multi-dimensional extents aggregated by the generator.

index_d template function

Syntax

```
template<int DimensionT, typename ObjT>
auto index_d(const ObjT &a_obj)
```

Description

The template function offers a consistent way to determine the index of a dimension for a multi-dimensional object. It can avoid extracting an entire `n_index_t<…>` when only the extent of a single dimension is needed.

Template Argument	Description
`int DimensionT`	0 based index starting at the leftmost dimension indicating which n-dimensions to query the index of. **Requirements:** DimensionT >=0 and DimensionT < ObjT::rank
`typename ObjT`	The type of n-dimensional object from which to retrieve the extent. **Requirements:** ObtT is one of: n_index_t<…> n_index_generator<…>

Returns

The correctly typed index corresponding to the requested DimensionT of a_obj.

Example

```
template <typename IndicesT>
void foo(const IndicesT & a_pos)
{
    int z = index_d<0>(a_pos);
    int y = index_d<1>(a_pos);
    int x = index_d<2>(a_pos);
    /…
}
```

Convenience and Correctness

Users can include a single header file `sdlt.h` that includes all the supported public features, or users can include the individual headers of features they will be using (which might build faster). In other words,

```
#include <sdlt/sdlt.h>
```

instead of

```
#include <sdlt/primitive.h>
#include <sdlt/soa1d_container.h>
```

For convenience, SDLT provides a macro to encapsulate `#pragma forceinline recursive`.

```
SDLT_INLINE_BLOCK
```

SDLT reduces overhead by trusting the programmer to pass it valid values for template and function parameters. Adding conditional checks inside of a SIMD loop can cause unnecessary code generation and inhibit vectorization by creating multiple exit points in a loop. To assist in verifying that a program is indeed passing valid values to SDLT, the programmer can add a compilation flag to their build to define `SDLT_DEBUG=1`.

```
-DSDLT_DEBUG=1
```

If `_DEBUG` is defined and `SDLT_DEBUG` has not been defined to 0 or 1, then `SDLT_DEBUG` is automatically set to 1. When set to 1, every operator[] is bounds checked and all addresses are validated for correct alignment. It is very useful for tracking down any usage bugs.

The macro `__SDLT_VERSION` is predefined to be 2001. Programs could use it for conditional compilation if incompatibilities arise in future updates.

C++ implementations of `std::min` and `std::max` sometimes have a negative impact on performance. SDLT defines `min_val` and `max_val` that help avoid such performance penalties.

max_val

Return the right value if the right value is greater than left, otherwise returns the left value. *`#include <sdlt/min_max_val.h>`*

Syntax

```
template<typename T>
T max_val(const T left, const T right);
```

Arguments

`typename T`	The type of the left and right values

Description

C++ implementations of std::min and std::max create a conditional control flow that returns references to its parameters, which may cause inefficient vector code generation. max_val is a really simple template that returns by value instead of reference, allowing more efficient vector code to be generated. For most cases the algorithm didn't need a reference to the inputs and a copy by value should suffice. It should inline, adding no overhead. Inside of SIMD loops, we suggest using sdlt::max_val in place of std::max.

Requires < operator be defined for the type T.

min_val

Return the left value if the right value is greater than left, otherwise returns the right value. *`#include <sdlt/min_max_val.h>`*

Syntax

```
template<typename T>
T min_val(const T left, const T right);
```

Arguments

`typename T`	The type of the left and right values

Description

C++ implementations of std::min and std::max create a conditional control flow that returns references to its parameters, which may cause inefficient vector code generation. min_val is a really simple template that returns by value instead of reference, allowing more efficient vector code to be generated. For most cases the algorithm didn't need a reference to the inputs and a copy by value should suffice. It should inline, adding no overhead. Inside of SIMD loops, we suggest using sdlt::min_val in place of std::min.

Requires < operator be defined for the type T.

Examples

The example programs in this section demonstrate

- the efficiency of using SDLT and its Structure of Arrays approach rather than a typical Array of Structures
- construction of more complex SDLT primitives,
- performance improvement in case of a forward-dependency
- use of offsets and calling methods on the SDLT primitive, and
- RGB to YUV conversion.

Efficiency with Structure of Arrays Example

This example demonstrates the efficiency of using a Structure of Arrays (SoA) approach by comparing the assembly generated from a simple SIMD loop using an Array of Structures (AoS) approach with the assembly generated using the SoA approach of SDLT.

Array of Structures: Non-unit stride access version

Source:

```
#include <stdio.h>

#define N 1024

typedef struct RGBs {
    float r;
    float g;
    float b;
} RGBTy;

void main()
{
    RGBTy a[N];
    #pragma omp simd
    for (int k = 0; k<N; ++k) {
        a[k].r = k*1.5;  // non-unit stride access
        a[k].g = k*2.5;  // non-unit stride access
        a[k].b = k*3.5;  // non-unit stride access
    }
    std::cout << "k =" << 10 <<
        ", a[k].r =" << a[10].r <<
        ", a[k].g =" << a[10].g <<
        ", a[k].b =" << a[10].b << std::endl;
}
```

Structure of Arrays: Using SDLT for unit stride access

To introduce the use of SDLT, the code below will:

- declare a primitive,
- use an `soa1d_container` instead of an array
- use an accessor inside a SIMD loop to generate efficient code
- use a proxy object's data member interface to access individual data members of an element inside the container

Source:

```
#include <stdio.h>
#include <sdlt/sdlt.h>

#define N 1024

typedef struct RGBs {
    float r;
    float g;
    float b;
} RGBTy;

SDLT_PRIMITIVE(RGBTy, r, g, b)

void main()
{
    // Use SDLT to get SOA data layout
    sdlt::soa1d_container<RGBTy> aContainer(N);
    auto a = aContainer.access();

    // use SDLT Data Member Interface to access struct members r, g, and b.
    // achieve unit-stride access after vectorization
    #pragma omp simd
    for (int k = 0; k<N; k++) {
        a[k].r() = k*1.5;
        a[k].g() = k*2.5;
        a[k].b() = k*3.5;
    }
    std::cout << "k =" << 10 <<
        ", a[k].r =" << a[10].r() <<
        ", a[k].g =" << a[10].g() <<
        ", a[k].b =" << a[10].b() << std::endl;
}
```

AVX2 assemply generated (19 instructions):

```
..TOP_OF_LOOP:
        vpaddd    %ymm4, %ymm3, %ymm12
        vcvtdq2ps %ymm3, %ymm7
```

```
        vcvtdq2ps %ymm12, %ymm10
        vmulps    %ymm7, %ymm2, %ymm5
        vmulps    %ymm7, %ymm1, %ymm6
        vmulps    %ymm7, %ymm0, %ymm8
        vmulps    %ymm10, %ymm2, %ymm3
        vmulps    %ymm10, %ymm1, %ymm9
        vmulps    %ymm10, %ymm0, %ymm11
        vmovups   %ymm5, (%r13,%rax,4)
        vmovups   %ymm6, (%r15,%rax,4)
        vmovups   %ymm8, (%rbx,%rax,4)
        vmovups   %ymm3, 32(%r13,%rax,4)
        vmovups   %ymm9, 32(%r15,%rax,4)
        vmovups   %ymm11, 32(%rbx,%rax,4)
        vpaddd    %ymm4, %ymm12, %ymm3
        addq      $16, %rax
        cmpq      $1024, %rax
        jb        ..TOP_OF_LOOP
```

Both versions appear to have unrolled the loop twice. When examining the assembly generated for AVX2 instruction set, we can see a measurable reduction in the number of instructions (19 vs. 69) when we are able to perform unit stride access using SDLT. Also, at runtime, the `soa1d_container` aligned its data allocation and will gain any of the architectural advantages that come with using aligned instead of unaligned SIMD stores.

Complex SDLT Primitive Construction Example

This example demonstrates use of nested primitives and the use of an accessor inside a SIMD loop to generate efficient code.

```
#include <stdio.h>
#include <sdlt/sdlt.h>

#define N 1024

typedef struct XYZs {
    float x;
    float y;
    float z;
} XYZTy;

SDLT_PRIMITIVE(XYZTy, x, y, z)

typedef struct RGBs {
    float r;
    float g;
    float b;
    XYZTy w;
} RGBTy;

SDLT_PRIMITIVE(RGBs, r, g, b, w)

void main()
{
    sdlt::soa1d_container<RGBTy> aContainer(N);
    auto a = aContainer.access();

    #pragma omp simd
    for (int k = 0; k<N; k++) {
        RGBTy c;
```

```
        c.r = k*1.5f;
        c.g = k*2.5f;
        c.b = k*3.5f;
        c.w.x = k*4.5f;
        c.w.y = k*5.5f;
        c.w.z = k*6.5f;
        a[k] = c;
    }
    const RGBTy c = a[10];
    printf("k = %d, a[k].r = %f, a[k].g = %f, a[k].b = %f \n",
        10, c.r, c.g, c.b);

    printf("k = %d, a[k].w.x = %f, a[k].w.y = %f, a[k].w.z = %f \n",
        10, c.w.x, c.w.y, c.w.z);
```

Forward Dependency Example

This example demonstrates the declaration of a Structure of Arrays (SoA) interacting with a forward dependency.

```
#include <stdio.h>
#include <sdlt/primitive.h>
#include <sdlt/soa1d_container.h>

#define N 1024

typedef struct RGBs {
    float r;
    float g;
    float b;
} RGBTy;

SDLT_PRIMITIVE(RGBTy, r, g, b)

void main()
{
    // RGBTy a[N];  // AOS data layout

    sdlt::soa1d_container<RGBTy> aContainer(N);
    auto a = aContainer.access();    // SOA data layout

    // use SDLT access method to access struct members r, g, and b.
    // with unit-stride access  after vectorization
    #pragma omp simd
    for (int k = 0; k<N; k++) {
        a[k].r() = k*1.5;
        a[k].g() = k*2.5;
        a[k].b() = k*3.5;
    }

    // Test forward-dependency on SOA memory access
    #pragma omp simd
    for (int i = 0; i<N - 1; i++) {
        sdlt::linear_index k(i);
        a[k].r() = a[k + 1].r() + k*1.5;
        a[k].g() = a[k + 1].g() + k*2.5;
        a[k].b() = a[k + 1].b() + k*3.5;
    }
    std::cout << "k =" << 10 <<
```

```
        ", a[k].r =" << a[10].r() <<
        ", a[k].g =" << a[10].g() <<
        ", a[k].b =" << a[10].b() << std::endl;
}
```

Use of Offsets and Methods on a SDLT Primitive Example

This example demonstrates a linearized 2d stencil using embedded offsets and calling methods on the primitive.

```
#include <sdlt/sdlt.h>

// Typical C++ object to represent a pixel in an image
struct RGBs
{
    float red;
    float green;
    float blue;

    RGBs() {}
    RGBs(const RGBs &iOther)
        : red(iOther.red)
        , green(iOther.green)
        , blue(iOther.blue)
    {
    }

    RGBs & operator =(const RGBs &iOther)
    {
        red = iOther.red;
        green = iOther.green;
        blue = iOther.blue;
        return *this;
    }

    RGBs operator + (const RGBs &iOther) const
    {
        RGBs sum;
        sum.red = red + iOther.red;
        sum.green = green + iOther.green;
        sum.blue = blue + iOther.blue;
        return sum;
    }

    RGBs operator * (float iScalar) const
    {
        RGBs scaledColor;
        scaledColor.red = red * iScalar;
        scaledColor.green = green * iScalar;
        scaledColor.blue = blue * iScalar;
        return scaledColor;
    }
};

SDLT_PRIMITIVE(RGBs, red, green, blue)

const int StencilHaloSize = 1;
const int width = 1920;
const int height = 1080;
```

```
template<typename AccessorT> void loadImageStub(AccessorT) {}
template<typename AccessorT> void saveImageStub(AccessorT) {}

// performs average color filtering with neighbors left,right,above,below
void main(void)
{
    // We are padding +-1 so we can avoid boundary conditions
    const int paddedWidth = width + 2 * StencilHaloSize;
    const int paddedHeight = height + 2 * StencilHaloSize;
    int elementCount = paddedWidth*paddedHeight;
    sdlt::soa1d_container<RGBs> inputImage(elementCount);
    sdlt::soa1d_container<RGBs> outputImage(elementCount);

    loadImageStub(inputImage.access());

    SDLT_INLINE_BLOCK
    {
        const int endOfY = StencilHaloSize + height;
        const int endOfX = StencilHaloSize + width;
        for (int y = StencilHaloSize; y < endOfY; ++y)
        {
            // Embed offsets into Accessors to get the to correct row
            auto prevRow = inputImage.const_access((y - 1)*paddedWidth);
            auto curRow = inputImage.const_access(y*paddedWidth);
            auto nextRow = inputImage.const_access((y + 1)*paddedWidth);

            auto outputRow = outputImage.access(y*paddedWidth);

            #pragma omp simd
            for (int ix = StencilHaloSize; ix < endOfX; ++ix)
            {
                sdlt::linear_index x(ix);

                const RGBs color1 = curRow[x - 1];
                const RGBs color2 = curRow[x];
                const RGBs color3 = curRow[x + 1];
                const RGBs color4 = prevRow[x];
                const RGBs color5 = nextRow[x];
                // Despite looking like AOS code, compiler is able to create
                // privatized instances and call inlinable methods on the objects
                // keeping the algorithm at very high level
                const RGBs sumOfColors = color1 + color2 + color3 + color4 + color5;
                const RGBs averageColor = sumOfColors*(1.0f / 5.0f);
                outputRow[x] = averageColor;
            }
        }
    }
    saveImageStub(outputImage.access());
}
```

RGB to YUV Conversion Example

This example converts a 2D image from the RGB format to the YUV format. It demonstrates how storing both images in 2D SoA `n_container`s can improve performance.

```
#include <iostream>
#include <sdlt/sdlt.h>
using namespace sdlt;
#define WIDTH 1024
#define HEIGHT 1024

struct RGBs {
    float r;
    float g;
    float b;
};

struct YUVs {
    float y;
    float u;
    float v;

    YUVs(){ };

    YUVs& operator=(const RGBs &tmp){
        y = 0.229f * tmp.r + 0.587f * tmp.g + 0.114f * tmp.b;
        u = -0.147f * tmp.r - 0.289f * tmp.g + 0.436f * tmp.b;
        v = 0.615 * tmp.r - 0.515f * tmp.g - 0.100 * tmp.b;
        return *this;
    }
    YUVs(const RGBs &tmp){
        y = 0.229f * tmp.r + 0.587f * tmp.g + 0.114f * tmp.b;
        u = -0.147f * tmp.r - 0.289f * tmp.g + 0.436f * tmp.b;
        v = 0.615 * tmp.r - 0.515f * tmp.g - 0.100 * tmp.b;
   }
};

SDLT_PRIMITIVE(RGBs, r, g, b)
SDLT_PRIMITIVE(YUVs, y, u, v)

int main(){
    typedef layout::soa<> LayoutT;
    n_extent_t<int, int> extents(HEIGHT, WIDTH);

    /*  Creating a typedef for SoA N-dimensional container.
        RGBTy and YUVTy are user defined structures whose collection needs to be stored in SoA
format in memory.
        Layout in memory specified as layout::soa.
        In the below case N-dimensional SoA container is used in 2-D context
    */
    typedef sdlt::n_container< RGBs, LayoutT, decltype(extents) > ContainerRGB;
    typedef sdlt::n_container< YUVs, LayoutT, decltype(extents) > ContainerYUV;

    //Instantiate Input and Output Containers
    ContainerRGB inputRGB(extents);
    ContainerYUV outputYUV(extents);

    auto input = inputRGB.const_access();   //Get Constant Accessor object for inputRGB
```

```
    auto output = outputYUV.access();       //Get Accessor object for outputYUV

    //Select the iteration range in each dimension
    const auto iRGB1 = bounds_d<1>(input);  //bound_d<1>(input);
    const auto iRGB0 = bounds_d<0>(input);  //bound_d<0>(input);

    for(int y = iRGB0.lower(); y < iRGB0.upper(); y++)
    {
        #pragma simd
        for (int x = iRGB1.lower(); x < iRGB1.upper(); x++){
            const RGBs temp1 = input[y][x];
            YUVs temp2 = temp1;
            output[y][x] = temp2;
        }
    }
    return 0;
}
```

Intel® C++ Class Libraries

The Intel® C++ Class Libraries enable Single-Instruction, Multiple-Data (SIMD) operations. The principle of SIMD operations is to exploit microprocessor architecture through parallel processing. The effect of parallel processing is increased data throughput using fewer clock cycles. The objective is to improve application performance of complex and computation-intensive audio, video, and graphical data bit streams.

Hardware and Software Requirements

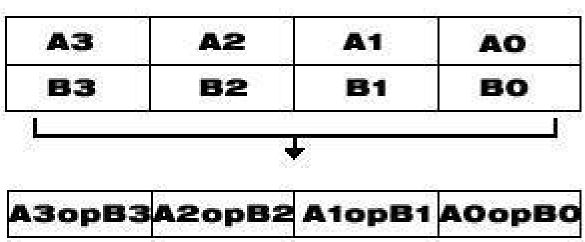
The Intel® C++ Class Libraries are functions abstracted from the instruction extensions available on Intel® processors.

Refer to http://software.intel.com/en-us/articles/performance-tools-for-software-developers-intel-compiler-options-for-sse-generation-and-processor-specific-optimizations/ for information on which Intel® processors use each instruction set.

Details About the Libraries

The Intel® C++ Class Libraries for SIMD Operations provide a convenient interface to access the underlying instructions for processors as specified above. These processor-instruction extensions enable parallel processing using the single instruction-multiple data (SIMD) technique as illustrated in the following figure.

SIMD Data Flow



Performing four operations with a single instruction improves efficiency by a factor of four for that particular instruction.

These new processor instructions can be implemented using assembly inlining, intrinsics, or the C++ SIMD classes. Compare the coding required to add four 32-bit floating-point values, using each of the available interfaces:

Comparison Between Inlining, Intrinsics and Class Libraries

Assembly Inlining	Intrinsics	SIMD Class Libraries
`... __m128 a,b,c; __asm{ movaps xmm0,b movaps xmm1,c addps xmm0,xmm1 movaps a, xmm0 } ...`	`#include <xmmintrin.h> ... __m128 a,b,c; a = _mm_add_ps(b,c); ...`	`#include <fvec.h> ... F32vec4 a,b,c; a = b +c; ...`

This table shows an addition of four single-precision floating-point values using assembly inlining, intrinsics, and the libraries. You can see how much easier it is to code with the Intel C++ SIMD Class Libraries. Besides using fewer keystrokes and fewer lines of code, the notation is like the standard notation in C++, making it much easier to implement over other methods.

C++ Classes and SIMD Operations

Use of C++ classes for SIMD operations allows for operating on arrays or vectors of data in a single operation. Consider the addition of two vectors, `A` and `B`, where each vector contains four elements. Using an integer vector class, the elements `A[i]` and `B[i]` from each array are summed as shown in the following example.

Typical Method of Adding Elements Using a Loop

```
int a[4], b[4], c[4];
for (i=0; i<4; i++) /* needs four iterations */
c[i] = a[i] + b[i]; /* computes c[0], c[1], c[2], c[3] */
```

The following example shows the same results using one operation with an integer class.

SIMD Method of Adding Elements Using Ivec Classes

```
Is16vec4 ivecA, ivecB, ivec C; /*needs one iteration*/
ivecC = ivecA + ivecB; /*computes ivecC0, ivecC1, ivecC2, ivecC3 */
```

Available Classes

The Intel® C++ SIMD classes provide parallelism, which is not easily implemented using typical mechanisms of C++. The following table shows how the Intel® C++ classes use the SIMD classes and libraries.

SIMD Vector Classes

Instruction Set	Class	Signedness	Data Type	Size	Elements	Header File
MMX™ technology	`I64vec1`	unspecified	`__m64`	64	1	`ivec.h`
	`I32vec2`	unspecified	`int`	32	2	`ivec.h`
	`Is32vec2`	signed	`int`	32	2	`ivec.h`
	`Iu32vec2`	unsigned	`int`	32	2	`ivec.h`
	`I16vec4`	unspecified	`short`	16	4	`ivec.h`
	`Is16vec4`	signed	`short`	16	4	`ivec.h`
	`Iu16vec4`	unsigned	`short`	16	4	`ivec.h`

Instruction Set	Class	Signedness	Data Type	Size	Elements	Header File
	I8vec8	unspecified	char	8	8	ivec.h
	Is8vec8	signed	char	8	8	ivec.h
	Iu8vec8	unsigned	char	8	8	ivec.h
Intel® SSE	F32vec4	unspecified	float	32	4	fvec.h
	F32vec1	unspecified	float	32	1	fvec.h
Intel® SSE2	F64vec2	unspecified	double	64	2	dvec.h
	I128vec1	unspecified	__m128i	128	1	dvec.h
	I64vec2	unspecified	long int	64	2	dvec.h
	I32vec4	unspecified	int	32	4	dvec.h
	Is32vec4	signed	int	32	4	dvec.h
	Iu32vec4	unsigned	int	32	4	dvec.h
	I16vec8	unspecified	int	16	8	dvec.h
	Is16vec8	signed	int	16	8	dvec.h
	Iu16vec8	unsigned	int	16	8	dvec.h
	I8vec16	unspecified	char	8	16	dvec.h
	Is8vec16	signed	char	8	16	dvec.h
	Iu8vec16	unsigned	char	8	16	dvec.h
Intel® AVX	F32vec8	unspecified	float	32	8	dvec.h
	F64vec4	unspecified	double	64	4	dvec.h
Intel® AVX-512 Foundation	F32vec16	unspecified	float	32	16	dvec.h
	F64vec8	unspecified	double	64	8	dvec.h
	M512vec	unspecified	__m512i	512	1	dvec.h
	I32vec16	unspecified	int	32	16	dvec.h
	Is32vec16	signed	int	32	16	dvec.h
	Iu32vec16	unsigned	int	32	16	dvec.h
	I64vec8	unspecified	long int	64	8	dvec.h
	Is64vec8	signed	long int	64	8	dvec.h
	Iu64vec8	unsigned	long int	64	8	dvec.h

Instruction Set	Class	Signedness	Data Type	Size	Elements	Header File
Intel® AVX-512 Byte and Word	I16vec32	unspecified	int	16	32	dvec.h
	Is16vec32	signed	int	16	32	dvec.h
	Iu16vec32	unsigned	int	16	32	dvec.h
	I8vec64	unspecified	int	8	64	dvec.h
	Is8vec64	signed	int	8	64	dvec.h
	Iu8vec64	unsigned	int	8	64	dvec.h

Most classes contain similar functionality for all data types and are represented by all available intrinsics. However, some capabilities do not translate from one data type to another without suffering from poor performance, and are therefore excluded from individual classes.

NOTE
Intrinsics that take immediate values and cannot be expressed easily in classes are not implemented. For example:

- `_mm_shuffle_ps`
- `_mm_shuffle_pi16`
- `_mm_shuffle_ps`
- `_mm_extract_pi16`
- `_mm_insert_pi16`

Access to Classes Using Header Files

The required class header files are installed in the include directory with the Intel® C++ Compiler. To enable the classes, use the `#include` directive in your program file as shown in the table that follows.

Include Directives for Enabling Classes

Instruction Set Extension	Include Directive
MMX™ Technology	`#include <ivec.h>`
Intel® SSE	`#include <fvec.h>`
Intel® SSE 2	`#include <dvec.h>`
Intel® SSE 3	`#include <dvec.h>`
Intel® SSE 4	`#include <dvec.h>`
Intel® AVX	`#include <dvec.h>`

Each succeeding file from the top down includes the preceding class. You only need to include `fvec.h` if you want to use both the `Ivec` and `Fvec` classes. Similarly, to use all the classes including those for Intel® Streaming SIMD Extensions 2, you only need to include the `dvec.h` file.

Usage Precautions

When using the C++ classes, you should follow some general guidelines. More detailed usage rules for each class are listed in Integer Vector Classes, and Floating-point Vector Classes.

Clear MMX Registers

If you use both the `Ivec` and `Fvec` classes at the same time, your program could mix Intel® MMX™ instructions, called by `Ivec` classes, with Intel® architecture floating-point instructions, called by `Fvec` classes. x87 floating-point instructions exist in the following `Fvec` functions:

- `fvec` constructors
- debug functions (`cout` and element access)
- `rsqrt_nr`

NOTE
Intel® MMX™ technology registers are aliased on the floating-point registers, so you should clear the MMX state with the EMMS instruction intrinsic before issuing an x87 floating-point instruction, as in the following example.

`ivecA = ivecA & ivecB;`	Ivec logical operation that uses MMX instructions
`empty ();`	clear state
`cout << f32vec4a;`	F32vec4 operation that uses x87 floating-point instructions

Caution
Failure to clear the Intel® MMX™ technology registers can result in incorrect execution or poor performance due to an incorrect register state.

Capabilities of C++ SIMD Classes

The fundamental capabilities of each C++ SIMD class include:

- Computation
- Horizontal data support
- Branch compression/elimination
- Caching hints

Understanding each of these capabilities and how they interact is crucial to achieving desired results.

Computation

The SIMD C++ classes contain vertical operator support for most arithmetic operations, including shifting and saturation.

Computation operations include: `+`, `-`, `*`, `/`, reciprocal (`rcp` and `rcp_nr`), square root (`sqrt`), and reciprocal square root (`rsqrt` and `rsqrt_nr`).

Operations `rcp` and `rsqrt` are approximating instructions with very short latencies that produce results with at least 12 bits of accuracy. You may get a different answer if used on non-Intel processors. Operations `rcp_nr` and `rsqrt_nr` use software refining techniques to enhance the accuracy of the approximations, with a minimal impact on performance. (The `nr` stands for Newton-Raphson, a mathematical technique for improving performance using an approximate result.)

Horizontal Data Support

The C++ SIMD classes provide horizontal support for some arithmetic operations. The term *horizontal* indicates computation across the elements of one vector, as opposed to the vertical, element-by-element operations on two different vectors.

The `add_horizontal`, `unpack_low` and `pack_sat` functions are examples of horizontal data support. This support enables certain algorithms that cannot exploit the full potential of SIMD instructions.

Shuffle intrinsics are another example of horizontal data flow. Shuffle intrinsics are not expressed in the C++ classes due to their immediate arguments. However, the C++ class implementation enables you to mix shuffle intrinsics with the other C++ functions. For example:

```
F32vec4 fveca, fvecb, fvecd;
fveca += fvecb;
fvecd = _mm_shuffle_ps(fveca,fvecb,0);
```

Branch Compression/Elimination

Branching in SIMD architectures can be complicated and expensive. The SIMD C++ classes provide functions to eliminate branches, using logical operations, max and min functions, conditional selects, and compares. Consider the following example:

```
short a[4], b[4], c[4];
for (i=0; i<4; i++)
c[i] = a[i] > b[i] ? a[i] : b[i];
```

This operation is independent of the value of `i`. For each `i`, the result could be either `A` or `B` depending on the actual values. A simple way of removing the branch altogether is to use the `select_gt` function, as follows:

```
Is16vec4 a, b, c
c = select_gt(a, b, a, b)
```

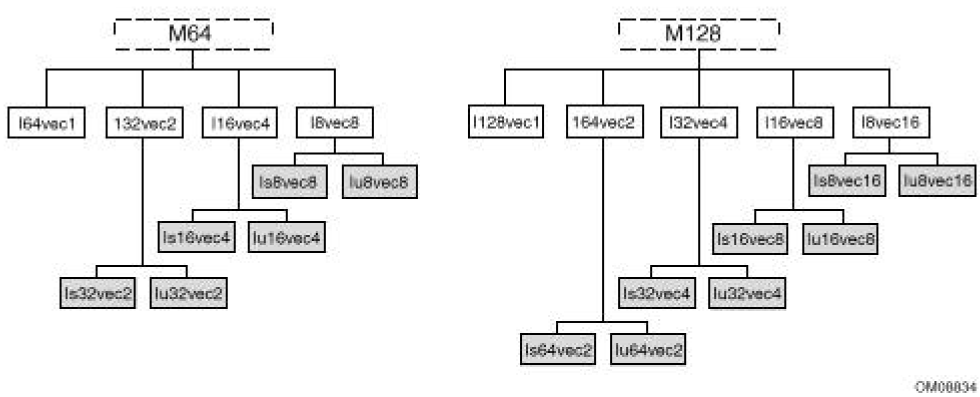
Caching Hints

Intel® Streaming SIMD Extensions provide prefetching and streaming hints. Prefetching data can minimize the effects of memory latency. Streaming hints allow you to indicate that certain data should not be cached.

Integer Vector Classes

The `Ivec` classes provide an interface to single instruction, multiple data (SIMD) processing using integer vectors of various sizes. The class hierarchy is represented in the following figure.

Ivec Class Hierarchy



The `M64` and `M128` classes define the `__m64` and `__m128i` data types from which the rest of the `Ivec` classes are derived. The first generation of child classes (the intermediate classes) are derived on element sizes of 128, 64, 32, 16, and 8 bits:

```
I128vec1, I64vec1, I64vec2, I32vec2, I32vec4, I16vec4, I16vec8, I8vec8, I8vec16
```

The second generation specify the signedness:

```
Is64vec2, Iu64vec2, Is32vec2, Iu32vec2, Is32vec4, Iu32vec4, Is16vec4, Iu16vec4,
Is16vec8, Iu16vec8, Is8vec8, Iu8vec8, Is8vec16, Iu8vec16
```

> **Caution**
> Intermixing the `M64` and `M128` data types will result in unexpected behavior.

Terms and Syntax

The following are special terms and syntax used in this chapter to describe functionality of the classes with respect to their associated operations.

Ivec Class Syntax Conventions

The name of each class denotes the data type, signedness, bit size, and number of elements using the following generic format:

```
<type><signedness><bits>vec<elements>
```

```
{ F | I } { s | u } { 128 | 64 | 32 | 16 | 8 } vec { 16 | 8 | 4 | 2 | 1 }
```

where

`type`	Indicates floating point (`F`) or integer (`I`).
`signedness`	Indicates signed (`s`) or unsigned (`u`). For the Ivec class, leaving this field blank indicates an intermediate class. For the Fvec classes, this field is blank because there are no unsigned Fvec classes.
`bits`	Specifies the number of bits per element.
`elements`	Specifies the number of elements.

Special Terms and Conventions

The following terms are used to define the functionality and characteristics of the classes and operations defined in this manual.

- **Nearest Common Ancestor**: This is the intermediate or parent class of two classes of the same size. For example, the nearest common ancestor of `Iu8vec8` and `Is8vec8` is `I8vec8`, and the nearest common ancestor between `Iu8vec8` and `I16vec4` is `M64`.
- **Casting:** Changes the data type from one class to another. When an operation uses different data types as operands, the return value of the operation must be assigned to a single data type, and one or more of the data types must be converted to a required data type. This conversion is known as a typecast. While typecasting is occasionally automatic, in cases where it is not automatic you must use special syntax to explicitly typecast it yourself.
- **Operator Overloading:** This is the ability to use various operators on the user-defined data type of a given class. In the case of the Ivec and Fvec classes, once you declare a variable, you can add, subtract, multiply, and perform a range of operations. Each family of classes accepts a specified range of operators, and must comply by rules and restrictions regarding typecasting and operator overloading as defined in the header files.

Rules for Operators

To use operators with the `Ivec` classes you must use one of the following three syntax conventions:

`[ Ivec_Class ] R = [ Ivec_Class ] A [ operator ][ Ivec_Class ] B`

Example 1:`I64vec1 R = I64vec1 A & I64vec1 B;`

`[ Ivec_Class ] R =[ operator ] ([ Ivec_Class ] A,[ Ivec_Class ] B)`

Example 2:`I64vec1 R = andnot(I64vec1 A, I64vec1 B);`

`[ Ivec_Class ] R [ operator ]= [ Ivec_Class ] A`

Example 3:`I64vec1 R &= I64vec1 A;`

[`operator`] represents an operator (for example, &, |, or ^)

[`Ivec_Class`] represents an `Ivec` class

`R`, `A`, `B` variables are declared using the pertinent `Ivec` classes

The table that follows shows automatic and explicit sign and size typecasting. "Explicit" means that it is illegal to mix different types without an explicit typecasting. "Automatic" means that you can mix types freely and the compiler will do the typecasting for you.

Summary of Rules Major Operators

Operators	Sign Typecasting	Size Typecasting	Other Typecasting Requirements
Assignment	N/A	N/A	N/A
Logical	Automatic	Automatic (to left)	Explicit typecasting is required for different types used in non-logical expressions on the right side of the assignment.
Addition and Subtraction	Automatic	Explicit	N/A
Multiplication	Automatic	Explicit	N/A
Shift	Automatic	Explicit	Casting Required to ensure arithmetic shift.
Compare	Automatic	Explicit	Explicit casting is required for signed classes for the less-than or greater-than operations.
Conditional Select	Automatic	Explicit	Explicit casting is required for signed classes for less-than or greater-than operations.

Data Declaration and Initialization

The following table shows literal examples of constructor declarations and data type initialization for all class sizes. All values are initialized with the most significant element on the left and the least significant to the right.

Declaration and Initialization Data Types for Ivec Classes

Operation	Class	Syntax
Declaration	`M128`	`I128vec1 A; Iu8vec16 A;`
Declaration	`M64`	`I64vec1 A; Iu8vec8 A;`
`__m128` Initialization	`M128`	`I128vec1 A(__m128 m);` `Iu16vec8(__m128 m);`
`__m64` Initialization	`M64`	`I64vec1 A(__m64 m);Iu8vec8 A(__m64 m);`
`__int64` Initialization	`M64`	`I64vec1 A = __int64 m;` `Iu8vec8 A =__int64 m;`
`int i` Initialization	`M64`	`I64vec1 A = int i; Iu8vec8 A = int i;`

`int` Initialization	`I32vec2`	`I32vec2 A(int A1, int A0);`
		`Is32vec2 A(signed int A1, signed int A0);`
		`Iu32vec2 A(unsigned int A1, unsigned int A0);`

`int` Initialization	`I32vec4`	`I32vec4 A(int A3, int A2, int A1, int A0);`
		`Is32vec4 A(signed int A3, ..., signed int A0);`
		`Iu32vec4 A(unsigned int A3, ..., unsigned int A0);`

`short int` Initialization	`I16vec4`	`I16vec4 A(short A3, short A2, short A1, short A0);`
		`Is16vec4 A(signed short A3, ..., signed short A0);`
		`Iu16vec4 A(unsigned short A3, ..., unsigned short A0);`

`short int` Initialization	`I16vec8`	`I16vec8 A(short A7, short A6, ..., short A1, short A0);`
		`Is16vec8 A(signed A7, ..., signed short A0);`
		`Iu16vec8 A(unsigned short A7, ..., unsigned short A0);`

`char` Initialization	`I8vec8`	`I8vec8 A(char A7, char A6, ..., char A1, char A0);`
		`Is8vec8 A(signed char A7, ..., signed char A0);`
		`Iu8vec8 A(unsigned char A7, ..., unsigned char A0);`

Operation	Class	Syntax
`char` Initialization	`I8vec16`	`I8vec16 A(char A15, ..., char A0);` `Is8vec16 A(signed char A15, ..., signed char A0);` `Iu8vec16 A(unsigned char A15, ..., unsigned char A0);`

Assignment Operator

Any `Ivec` object can be assigned to any other `Ivec` object; conversion on assignment from one `Ivec` object to another is automatic.

Assignment Operator Examples

```
Is16vec4 A;

Is8vec8 B;

I64vec1 C;

A = B; /* assign Is8vec8 to Is16vec4 */

B = C; /* assign I64vec1 to Is8vec8 */

B = A & C; /* assign M64 result of '&' to Is8vec8 */
```

Logical Operators

The logical operators use the symbols and intrinsics listed in the following table.

Bitwise Operation	Operator Symbols		Syntax Usage		Corresponding Intrinsic
	Standard	w/assign	Standard	w/assign	
AND	`&`	`&=`	`R = A & B`	`R &= A`	`_mm_and_si64` `_mm_and_si128`
OR	`|`	`|=`	`R = A | B`	`R |= A`	`_mm_and_si64` `_mm_and_si128`
XOR	^	^=	R = A^B	R ^= A	`_mm_and_si64` `_mm_and_si128`
ANDNOT	`andnot`	`N/A`	`R = A andnot B`	`N/A`	`_mm_and_si64` `_mm_and_si128`

Logical Operators and Miscellaneous Exceptions

A and B converted to M64. Result assigned to `Iu8vec8`.

```
I64vec1 A;

Is8vec8 B;

Iu8vec8 C;

C = A & B;
```

Same size and signedness operators return the nearest common ancestor.

```
I32vec2 R = Is32vec2 A ^ Iu32vec2 B;
```

A&B returns M64, which is cast to `Iu8vec8`.

```
C = Iu8vec8(A&B)+ C;
```

When `A` and `B` are of the same class, they return the same type. When `A` and `B` are of different classes, the return value is the return type of the nearest common ancestor.

The logical operator returns values for combinations of classes, listed in the following tables, apply when `A` and `B` are of different classes.

Ivec Logical Operator Overloading

Return (R)	AND	OR	XOR	NAND	A Operand	B Operand
`I64vec1 R`	`&`	`|`	`^`	`andnot`	`I[s|u]64vec2 A`	`I[s|u]64vec2 B`
`I64vec2 R`	`&`	`|`	`^`	`andnot`	`I[s|u]64vec2 A`	`I[s|u]64vec2 B`
`I32vec2 R`	`&`	`|`	`^`	`andnot`	`I[s|u]32vec2 A`	`I[s|u]32vec2 B`
`I32vec4 R`	`&`	`|`	`^`	`andnot`	`I[s|u]32vec4 A`	`I[s|u]32vec4 B`
`I16vec4 R`	`&`	`|`	`^`	`andnot`	`I[s|u]16vec4 A`	`I[s|u]16vec4 B`
`I16vec8 R`	`&`	`|`	`^`	`andnot`	`I[s|u]16vec8 A`	`I[s|u]16vec8 B`
`I8vec8 R`	`&`	`|`	`^`	`andnot`	`I[s|u]8vec8 A`	`I[s|u]8vec8 B`
`I8vec16 R`	`&`	`|`	`^`	`andnot`	`I[s|u]8vec16 A`	`I[s|u]8vec16 B`

For logical operators with assignment, the return value of `R` is always the same data type as the pre-declared value of R as listed in the table that follows.

Ivec Logical Operator Overloading with Assignment

Return Type	Left Side (R)	AND	OR	XOR	Right Side (Any Ivec Type)
`I128vec1`	`I128vec1 R`	`&=`	`|=`	`^=`	`I[s|u][N]vec[N] A;`
`I64vec1`	`I64vec1 R`	`&=`	`|=`	`^=`	`I[s|u][N]vec[N] A;`
`I64vec2`	`I64vec2 R`	`&=`	`|=`	`^=`	`I[s|u][N]vec[N] A;`
`I[x]32vec4`	`I[x]32vec4 R`	`&=`	`|=`	`^=`	`I[s|u][N]vec[N] A;`
`I[x]32vec2`	`I[x]32vec2 R`	`&=`	`|=`	`^=`	`I[s|u][N]vec[N] A;`
`I[x]16vec8`	`I[x]16vec8 R`	`&=`	`|=`	`^=`	`I[s|u][N]vec[N] A;`
`I[x]16vec4`	`I[x]16vec4 R`	`&=`	`|=`	`^=`	`I[s|u][N]vec[N] A;`

Return Type	Left Side (R)	AND	OR	XOR	Right Side (Any Ivec Type)
`I[x]8vec16`	`I[x]8vec16 R`	`&=`	`|=`	`^=`	`I[s|u][N]vec[N] A;`
`I[x]8vec8`	`I[x]8vec8 R`	`&=`	`|=`	`^=`	`I[s|u][N]vec[N] A;`

Addition and Subtraction Operators

The addition and subtraction operators return the class of the nearest common ancestor when the right-side operands are of different signs. The following code provides examples of usage and miscellaneous exceptions.

Syntax Usage for Addition and Subtraction Operators

Return nearest common ancestor type, `I16vec4`.

```
Is16vec4 A;

Iu16vec4 B;

I16vec4 C;

C = A + B;
```

Returns type left-hand operand type.

```
Is16vec4 A;

Iu16vec4 B;

A += B;

B -= A;
```

Explicitly convert `B` to `Is16vec4`.

```
Is16vec4 A,C;

Iu32vec24 B;

C = A + C;

C = A + (Is16vec4)B;
```

Addition and Subtraction Operators with Corresponding Intrinsics

Operation	Symbols	Syntax	Corresponding Intrinsics

Addition	`+`
	`+=`
		`R = A + B`
		`R += A`
			`_mm_add_epi64`
			`_mm_add_epi32`
			`_mm_add_epi16`
			`_mm_add_epi8`
			`_mm_add_pi32`
			`_mm_add_pi16`
			`_mm_add_pi8`

Subtraction	`-`
	`-=`
		`R = A - B`
		`R -= A`
			`_mm_sub_epi64`
			`_mm_sub_epi32`
			`_mm_sub_epi16`
			`_mm_sub_epi8`
			`_mm_sub_pi32`
			`_mm_sub_pi16`
			`_mm_sub_pi8`

The following table lists addition and subtraction return values for combinations of classes when the right side operands are of different signedness. The two operands must be the same size, otherwise you must explicitly indicate the typecasting.

Addition and Subtraction Operator Overloading

Return Value	Available Operators		Right Side Operands	
R	**Add**	**Sub**	**A**	**B**
`I64vec2 R`	`+`	`-`	`I[s|u]64vec2 A`	`I[s|u]64vec2 B`
`I32vec4 R`	`+`	`-`	`I[s|u]32vec4 A`	`I[s|u]32vec4 B`
`I32vec2 R`	`+`	`-`	`I[s|u]32vec2 A`	`I[s|u]32vec2 B`
`I16vec8 R`	`+`	`-`	`I[s|u]16vec8 A`	`I[s|u]16vec8 B`
`I16vec4 R`	`+`	`-`	`I[s|u]16vec4 A`	`I[s|u]16vec4 B`
`I8vec8 R`	`+`	`-`	`I[s|u]8vec8 A`	`I[s|u]8vec8 B`
`I8vec16 R`	`+`	`-`	`I[s|u]8vec2 A`	`I[s|u]8vec16 B`

The following table shows the return data type values for operands of the addition and subtraction operators with assignment. The left side operand determines the size and signedness of the return value. The right side operand must be the same size as the left operand; otherwise, you must use an explicit typecast.

Addition and Subtraction with Assignment

Return Value (R)	Left Side (R)	Add	Sub	Right Side (A)
`I[x]32vec4`	`I[x]32vec2 R`	`+=`	`-=`	`I[s|u]32vec4 A;`
`I[x]32vec2 R`	`I[x]32vec2 R`	`+=`	`-=`	`I[s|u]32vec2 A;`
`I[x]16vec8`	`I[x]16vec8`	`+=`	`-=`	`I[s|u]16vec8 A;`
`I[x]16vec4`	`I[x]16vec4`	`+=`	`-=`	`I[s|u]16vec4 A;`
`I[x]8vec16`	`I[x]8vec16`	`+=`	`-=`	`I[s|u]8vec16 A;`
`I[x]8vec8`	`I[x]8vec8`	`+=`	`-=`	`I[s|u]8vec8 A;`

Multiplication Operators

The multiplication operators can only accept and return data types from the `I[s|u]16vec4` or `I[s|u]16vec8` classes, as shown in the following example.

Syntax Usage for Multiplication Operators

Explicitly convert B to `Is16vec4`.

```
Is16vec4 A,C;

Iu32vec2 B;

C = A * C;

C = A * (Is16vec4)B;
```

Return nearest common ancestor type, `I16vec4`

```
Is16vec4 A;

Iu16vec4 B;

I16vec4 C;
```

```
C = A + B;
```

The `mul_high` and `mul_add` functions take `Is16vec4` data only.

```
Is16vec4 A,B,C,D;
C = mul_high(A,B);
D = mul_add(A,B);
```

Multiplication Operators with Corresponding Intrinsics

Symbols		Syntax Usage	Intrinsic
*	*=	R = A * B R *= A	`_mm_mullo_pi16` `_mm_mullo_epi16`
`mul_high`	N/A	`R = mul_high(A, B)`	`_mm_mulhi_pi16` `_mm_mulhi_epi16`
`mul_add`	N/A	`R = mul_high(A, B)`	`_mm_madd_pi16` `_mm_madd_epi16`

The multiplication return operators always return the nearest common ancestor as listed in the table that follows. The two operands must be 16 bits in size, otherwise you must explicitly indicate typecasting.

Multiplication Operator Overloading

R	Mul	A	B
`I16vec4 R`	`*`	`I[s|u]16vec4 A`	`I[s|u]16vec4 B`
`I16vec8 R`	`*`	`I[s|u]16vec8 A`	`I[s|u]16vec8 B`
`Is16vec4 R`	`mul_add`	`Is16vec4 A`	`Is16vec4 B`
`Is16vec8`	`mul_add`	`Is16vec8 A`	`Is16vec8 B`
`Is32vec2 R`	`mul_high`	`Is16vec4 A`	`Is16vec4 B`
`Is32vec4 R`	`mul_high`	`s16vec8 A`	`Is16vec8 B`

The following table shows the return values and data type assignments for operands of the multiplication operators with assignment. All operands must be 16 bytes in size. If the operands are not the right size, you must use an explicit typecast.

Multiplication with Assignment

Return Value (R)	Left Side (R)	Mul	Right Side (A)
`I[x]16vec8`	`I[x]16vec8`	`*=`	`I[s|u]16vec8 A;`
`I[x]16vec4`	`I[x]16vec4`	`*=`	`I[s|u]16vec4 A;`

Shift Operators

The right shift argument can be any integer or Ivec value, and is implicitly converted to a M64 data type. The first or left operand of a << can be of any type except `I[s|u]8vec[8|16]`.

Example Syntax Usage for Shift Operators

Automatic size and sign conversion.

```
Is16vec4 A,C;
Iu32vec2 B;
```

`C = A;`

A&B returns `I16vec4`, which must be cast to `Iu16vec4` to ensure logical shift, not arithmetic shift.

```
Is16vec4 A, C;
Iu16vec4 B, R;
R = (Iu16vec4)(A & B) C;
```

A&B returns `I16vec4`, which must be cast to `Is16vec4` to ensure arithmetic shift, not logical shift.

```
R = (Is16vec4)(A & B) C;
```

Shift Operators with Corresponding Intrinsics

Operation	Symbols	Syntax Usage	Intrinsic

Shift Left	`<<`
	`&=`
		`R = A << B`
		`R &= A`
			`_mm_sll_si64`
			`_mm_slli_si64`
			`_mm_sll_pi32`
			`_mm_slli_pi32`
			`_mm_sll_pi16`
			`_mm_slli_pi16`

Shift Right	`>>`	`R = A >> B`
		`R >>= A`
			`_mm_srl_si64`
			`_mm_srli_si64`
			`_mm_srl_pi32`
			`_mm_srli_pi32`
			`_mm_srl_pi16`
			`_mm_srli_pi16`
			`_mm_sra_pi32`
			`_mm_srai_pi32`
			`_mm_sra_pi16`
			`_mm_srai_pi16`

Right shift operations with signed data types use arithmetic shifts. All unsigned and intermediate classes correspond to logical shifts. The following table shows how the return type is determined by the first argument type.

Shift Operator Overloading

Option	R	Right Shift		Left Shift		A	B
Logical	`I64vec1`	>>	>>=	<<	<<=	`I64vec1 A;`	`I64vec1 B;`
Logical	`I32vec2`	>>	>>=	<<	<<=	`I32vec2 A`	`I32vec2 B;`
Arithmetic	`Is32vec2`	>>	>>=	<<	<<=	`Is32vec2 A`	`I[s|u][N]vec[N] B;`
Logical	`Iu32vec2`	>>	>>=	<<	<<=	`Iu32vec2 A`	`I[s|u][N]vec[N] B;`
Logical	`I16vec4`	>>	>>=	<<	<<=	`I16vec4 A`	`I16vec4 B`

Option	R	Right Shift		Left Shift		A	B
Arithmetic	Is16vec4	>>	>>=	<<	<<=	Is16vec4 A	I[s|u][N]vec[N] B;
Logical	Iu16vec4	>>	>>=	<<	<<=	Iu16vec4 A	I[s|u][N]vec[N] B;

Comparison Operators

The equality and inequality comparison operands can have mixed signedness, but they must be of the same size. The comparison operators for less-than and greater-than must be of the same sign and size.

Example of Syntax Usage for Comparison Operator

The nearest common ancestor is returned for compare for equal/not-equal operations.

```
Iu8vec8 A;
Is8vec8 B;
I8vec8 C;
C = cmpneq(A,B);
```

Type cast needed for different-sized elements for equal/not-equal comparisons.

```
Iu8vec8 A, C;
Is16vec4 B;
C = cmpeq(A,(Iu8vec8)B);
```

Type cast needed for sign or size differences for less-than and greater-than comparisons.

```
Iu16vec4 A;
Is16vec4 B, C;
C = cmpge((Is16vec4)A,B);
C = cmpgt(B,C);
```

Inequality Comparison Symbols and Corresponding Intrinsics

Compare For:	Operators	Syntax	Intrinsic
Equality	cmpeq	R = cmpeq(A, B)	_mm_cmpeq_pi32 _mm_cmpeq_pi16 _mm_cmpeq_pi8
Inequality	cmpneq	R = cmpneq(A, B)	_mm_cmpeq_pi32 _mm_cmpeq_pi16 _mm_cmpeq_pi8 _mm_andnot_si64
Greater Than	cmpgt	R = cmpgt(A, B)	_mm_cmpgt_pi32 _mm_cmpgt_pi16 _mm_cmpgt_pi8
Greater Than or Equal To	cmpge	R = cmpge(A, B)	_mm_cmpgt_pi32 _mm_cmpgt_pi16 _mm_cmpgt_pi8 _mm_andnot_si64

Compare For:	Operators	Syntax	Intrinsic

Less Than	`cmplt`	`R = cmplt(A, B)`	`_mm_cmpgt_pi32`
			`_mm_cmpgt_pi16`
			`_mm_cmpgt_pi8`

Less Than or Equal To	`cmple`	`R = cmple(A, B)`	`_mm_cmpgt_pi32`
			`_mm_cmpgt_pi16`
			`_mm_cmpgt_pi8`
			`_mm_andnot_si64`

Comparison operators have the restriction that the operands must be the size and sign as listed in the Compare Operator Overloading table.

Compare Operator Overloading

R	Comparison	A	B
`I32vec2 R`	`cmpeq` `cmpne`	`I[s|u]32vec2 B`	`I[s|u]32vec2 B`
`I16vec4 R`		`I[s|u]16vec4 B`	`I[s|u]16vec4 B`
`I8vec8 R`		`I[s|u]8vec8 B`	`I[s|u]8vec8 B`

`I32vec2 R`	`cmpgt`
	`cmpge`
	`cmplt`
	`cmple`
		`Is32vec2 B`	`Is32vec2 B`

`I16vec4 R`		`Is16vec4 B`	`Is16vec4 B`
`I8vec8 R`		`Is8vec8 B`	`Is8vec8 B`

Conditional Select Operators

For conditional select operands, the third and fourth operands determine the type returned. Third and fourth operands with same size, but different signedness, return the nearest common ancestor data type.

Conditional Select Syntax Usage

Return the nearest common ancestor data type if third and fourth operands are of the same size, but different signs.

```
I16vec4 R = select_neq(Is16vec4, Is16vec4, Is16vec4, Iu16vec4);
```

Conditional Select for Equality

```
R0 := (A0 == B0) ? C0 : D0;
R1 := (A1 == B1) ? C1 : D1;
R2 := (A2 == B2) ? C2 : D2;
R3 := (A3 == B3) ? C3 : D3;
```

Conditional Select for Inequality

```
R0 := (A0 != B0) ? C0 : D0;
R1 := (A1 != B1) ? C1 : D1;
R2 := (A2 != B2) ? C2 : D2;
R3 := (A3 != B3) ? C3 : D3;
```

Conditional Select Symbols and Corresponding Intrinsics

Conditional Select For:	Operators	Syntax	Corresponding Intrinsic	Additional Intrinsic (Applies to All)
Equality	`select_eq`	`R = select_eq(A, B, C, D)`	`_mm_cmpeq_pi32` `_mm_cmpeq_pi16` `_mm_cmpeq_pi8`	`_mm_and_si64` `_mm_or_si64` `_mm_andnot_si64`
Inequality	`select_neq`	`R = select_neq(A, B, C, D)`	`_mm_cmpeq_pi32` `_mm_cmpeq_pi16` `_mm_cmpeq_pi8`	
Greater Than	`select_gt`	`R = select_gt(A, B, C, D)`	`_mm_cmpgt_pi32` `_mm_cmpgt_pi16` `_mm_cmpgt_pi8`	
Greater Than or Equal To	`select_ge`	`R = select_gt(A, B, C, D)`	`_mm_cmpge_pi32` `_mm_cmpge_pi16` `_mm_cmpge_pi8`	
Less Than	`select_lt`	`R = select_lt(A, B, C, D)`	`_mm_cmplt_pi32` `_mm_cmplt_pi16` `_mm_cmplt_pi8`	
Less Than or Equal To	`select_le`	`R = select_le(A, B, C, D)`	`_mm_cmple_pi32` `_mm_cmple_pi16` `_mm_cmple_pi8`	

All conditional select operands must be of the same size. The return data type is the nearest common ancestor of operands `C` and `D`. For conditional select operations using greater-than or less-than operations, the first and second operands must be signed as listed in the table that follows.

Conditional Select Operator Overloading

R	Comparison	A and B	C	D
`I32vec2 R`	`select_eq` `select_ne`	`I[s|u]32vec2`	`I[s|u]32vec2`	`I[s|u]32vec2`
`I16vec4 R`			`I[s|u]16vec4`	`I[s|u]16vec4`
`I8vec8 R`			`I[s|u]8vec8`	`I[s|u]8vec8`
`I32vec2 R`	`select_gt` `select_ge` `select_lt` `select_le`	`Is32vec2`	`Is32vec2`	`Is32vec2`
`I16vec4 R`			`Is16vec4`	`Is16vec4`
`I8vec8 R`			`Is8vec8`	`Is8vec8`

The following table shows the mapping of return values from `R0` to `R7` for any number of elements. The same return value mappings also apply when there are fewer than four return values.

Conditional Select Operator Return Value Mapping

Return Value	A Operands	Available Operators						B Operands	C and D Operands
R0:=	A0	==	!=	>	>=	<	<=	B0	C0 : D0;

Return Value	A Operands	Available Operators						B Operands	C and D Operands
R1:=	A0	==	!=	>	>=	<	<=	B0	C1 : D1;
R2:=	A0	==	!=	>	>=	<	<=	B0	C2 : D2;
R3:=	A0	==	!=	>	>=	<	<=	B0	C3 : D3;
R4:=	A0	==	!=	>	>=	<	<=	B0	C4 : D4;
R5:=	A0	==	!=	>	>=	<	<=	B0	C5 : D5;
R6:=	A0	==	!=	>	>=	<	<=	B0	C6 : D6;
R7:=	A0	==	!=	>	>=	<	<=	B0	C7 : D7;

Debug Operations

The debug operations do not map to any compiler intrinsics for MMX™ instructions. They are provided for debugging programs only. Use of these operations may result in loss of performance, so you should not use them outside of debugging.

Output

The four 32-bit values of `A` are placed in the output buffer and printed in the following format (default in decimal):

```
cout << Is32vec4 A;
```

```
cout << Iu32vec4 A;
```

```
cout << hex << Iu32vec4 A; /* print in hex format */
```

```
"[3]:A3 [2]:A2 [1]:A1 [0]:A0"
```

Corresponding Intrinsics: none

The two 32-bit values of `A` are placed in the output buffer and printed in the following format (default in decimal):

```
cout << Is32vec2 A;
```

```
cout << Iu32vec2 A;
```

```
cout << hex << Iu32vec2 A; /* print in hex format */
```

```
"[1]:A1 [0]:A0"
```

Corresponding Intrinsics: none

The eight 16-bit values of `A` are placed in the output buffer and printed in the following format (default in decimal):

```
cout << Is16vec8 A;
```

```
cout << Iu16vec8 A;
```

```
cout << hex << Iu16vec8 A; /* print in hex format */
```

```
"[7]:A7 [6]:A6 [5]:A5 [4]:A4 [3]:A3 [2]:A2 [1]:A1 [0]:A0"
```

Corresponding Intrinsics: none

The four 16-bit values of `A` are placed in the output buffer and printed in the following format (default in decimal):

```
cout << Is16vec4 A;
```

```
cout << Iu16vec4 A;
```

```
cout << hex << Iu16vec4 A; /* print in hex format */
```

```
"[3]:A3 [2]:A2 [1]:A1 [0]:A0"
```

Corresponding Intrinsics: none

The sixteen 8-bit values of `A` are placed in the output buffer and printed in the following format (default is decimal):

```
cout << Is8vec16 A; cout << Iu8vec16 A; cout << hex << Iu8vec8 A;
```

```
/* print in hex format instead of decimal*/
```

```
"[15]:A15 [14]:A14 [13]:A13 [12]:A12 [11]:A11 [10]:A10 [9]:A9 [8]:A8 [7]:A7 [6]:A6
[5]:A5 [4]:A4 [3]:A3 [2]:A2 [1]:A1 [0]:A0"
```

Corresponding Intrinsics: none

The eight 8-bit values of `A` are placed in the output buffer and printed in the following format (default is decimal):

```
cout << Is8vec8 A; cout << Iu8vec8 A;cout << hex << Iu8vec8 A;
```

```
/* print in hex format instead of decimal*/
```

```
"[7]:A7 [6]:A6 [5]:A5 [4]:A4 [3]:A3 [2]:A2 [1]:A1 [0]:A0"
```

Corresponding Intrinsics: none

Element Access Operators

```
int R = Is64vec2 A[i];
```

```
unsigned int R = Iu64vec2 A[i];
```

```
int R = Is32vec4 A[i];
```

```
unsigned int R = Iu32vec4 A[i];
```

```
int R = Is32vec2 A[i];
```

```
unsigned int R = Iu32vec2 A[i];
```

```
short R = Is16vec8 A[i];
```

```
unsigned short R = Iu16vec8 A[i];
```

```
short R = Is16vec4 A[i];
```

```
unsigned short R = Iu16vec4 A[i];
```

```
signed char R = Is8vec16 A[i];
```

```
unsigned char R = Iu8vec16 A[i];
```

```
signed char R = Is8vec8 A[i];
```

```
unsigned char R = Iu8vec8 A[i];
```

Access and read element `i` of `A`. If DEBUG is enabled and the user tries to access an element outside of `A`, a diagnostic message is printed and the program aborts.

Corresponding Intrinsics: none

Element Assignment Operators

```
Is64vec2 A[i] = int R;
```

```
Is32vec4 A[i] = int R;
```

```
Iu32vec4 A[i] = unsigned int R;
```

```
Is32vec2 A[i] = int R;
```

```
Iu32vec2 A[i] = unsigned int R;
```

```
Is16vec8 A[i] = short R;
```

```
Iu16vec8 A[i] = unsigned short R;
```

```
Is16vec4 A[i] = short R;
```

```
Iu16vec4 A[i] = unsigned short R;
```

```
Is8vec16 A[i] = signed char R;
```

```
Iu8vec16 A[i] = unsigned char R;
```

```
Is8vec8 A[i] = signed char R;
```

```
Iu8vec8 A[i] = unsigned char R;
```

Assign `R` to element i of `A`. If `DEBUG` is enabled and the user tries to assign a value to an element outside of `A`, a diagnostic message is printed and the program aborts.

Corresponding Intrinsics: none

Unpack Operators

Interleave the 64-bit value from the high half of `A` with the 64-bit value from the high half of `B`.

```
I64vec2 unpack_high(I64vec2 A, I64vec2 B);
```

```
Is64vec2 unpack_high(Is64vec2 A, Is64vec2 B);
```

```
Iu64vec2 unpack_high(Iu64vec2 A, Iu64vec2 B);
```

```
R0 = A1;
R1 = B1;
```

Corresponding intrinsic: `_mm_unpackhi_epi64`

Interleave the two 32-bit values from the high half of `A` with the two 32-bit values from the high half of `B`.

```
I32vec4 unpack_high(I32vec4 A, I32vec4 B);
```

```
Is32vec4 unpack_high(Is32vec4 A, Is32vec4 B);
```

```
Iu32vec4 unpack_high(Iu32vec4 A, Iu32vec4 B);
```

```
R0 = A1;
R1 = B1;
R2 = A2;
R3 = B2;
```

Corresponding intrinsic: `_mm_unpackhi_epi32`

Interleave the 32-bit value from the high half of `A` with the 32-bit value from the high half of `B`.

```
I32vec2 unpack_high(I32vec2 A, I32vec2 B);
```

```
Is32vec2 unpack_high(Is32vec2 A, Is32vec2 B);
```

```
Iu32vec2 unpack_high(Iu32vec2 A, Iu32vec2 B);
```

```
R0 = A1;
R1 = B1;
```

Corresponding intrinsic: `_mm_unpackhi_pi32`

Interleave the four 16-bit values from the high half of `A` with the two 16-bit values from the high half of `B`.

```
I16vec8 unpack_high(I16vec8 A, I16vec8 B);
```

```
Is16vec8 unpack_high(Is16vec8 A, Is16vec8 B);
```

```
Iu16vec8 unpack_high(Iu16vec8 A, Iu16vec8 B);
```

```
R0 = A2;
R1 = B2;
R2 = A3;
R3 = B3;
```

Corresponding intrinsic: `_mm_unpackhi_epi16`

Interleave the two 16-bit values from the high half of `A` with the two 16-bit values from the high half of `B`.

```
I16vec4 unpack_high(I16vec4 A, I16vec4 B);
```

```
Is16vec4 unpack_high(Is16vec4 A, Is16vec4 B);
```

```
Iu16vec4 unpack_high(Iu16vec4 A, Iu16vec4 B);
```

```
R0 = A2;R1 = B2;
R2 = A3;R3 = B3;
```

Corresponding intrinsic: `_mm_unpackhi_pi16`

Interleave the four 8-bit values from the high half of `A` with the four 8-bit values from the high half of `B`.

```
I8vec8 unpack_high(I8vec8 A, I8vec8 B);
```

```
Is8vec8 unpack_high(Is8vec8 A, I8vec8 B);
```

```
Iu8vec8 unpack_high(Iu8vec8 A, I8vec8 B);
```

```

Pack Operators

Pack the eight 32-bit values found in `A` and `B` into eight 16-bit values with signed saturation.

`Is16vec8 pack_sat(Is32vec2 A,Is32vec2 B);`
Corresponding intrinsic: `_mm_packs_epi32`

Pack the four 32-bit values found in `A` and `B` into eight 16-bit values with signed saturation.

`Is16vec4 pack_sat(Is32vec2 A,Is32vec2 B);`
Corresponding intrinsic: `_mm_packs_pi32`

Pack the sixteen 16-bit values found in `A` and `B` into sixteen 8-bit values with signed saturation.

`Is8vec16 pack_sat(Is16vec4 A,Is16vec4 B);`
Corresponding intrinsic: `_mm_packs_epi16`

Pack the eight 16-bit values found in `A` and `B` into eight 8-bit values with signed saturation.

`Is8vec8 pack_sat(Is16vec4 A,Is16vec4 B);`
Corresponding intrinsic: `_mm_packs_pi16`

Pack the sixteen 16-bit values found in `A` and `B` into sixteen 8-bit values with unsigned saturation.

`Iu8vec16 packu_sat(Is16vec4 A,Is16vec4 B);`
Corresponding intrinsic: `_mm_packus_epi16`

Pack the eight 16-bit values found in `A` and `B` into eight 8-bit values with unsigned saturation.

`Iu8vec8 packu_sat(Is16vec4 A,Is16vec4 B);`
Corresponding intrinsic: `_mm_packs_pu16`

Clear MMX™ State Operator

Empty the MMX™ registers and clear the MMX state. Read the guidelines for using the EMMS instruction intrinsic.

`void empty(void);`
Corresponding intrinsic: `_mm_empty`

Integer Functions for Streaming SIMD Extensions

NOTE
You must include `fvec.h` header file for the following functionality.

Compute the element-wise maximum of the respective signed integer words in `A` and `B`.

`Is16vec4 simd_max(Is16vec4 A, Is16vec4 B);`
Corresponding intrinsic: `_mm_max_pi16`

Compute the element-wise minimum of the respective signed integer words in `A` and `B`.

`Is16vec4 simd_min(Is16vec4 A, Is16vec4 B);`
Corresponding intrinsic: `_mm_min_pi16`

Compute the element-wise maximum of the respective unsigned bytes in `A` and `B`.

```
Iu8vec8 simd_max(Iu8vec8 A, Iu8vec8 B);
```
Corresponding intrinsic: `_mm_max_pu8`

Compute the element-wise minimum of the respective unsigned bytes in `A` and `B`.

```
Iu8vec8 simd_min(Iu8vec8 A, Iu8vec8 B);
```
Corresponding intrinsic: `_mm_min_pu8`

Create an 8-bit mask from the most significant bits of the bytes in `A`.

```
int move_mask(I8vec8 A);
```
Corresponding intrinsic: `_mm_movemask_pi8`

Conditionally store byte elements of `A` to address `p`. The high bit of each byte in the selector `B` determines whether the corresponding byte in `A` will be stored.

```
void mask_move(I8vec8 A, I8vec8 B, signed char *p);
```
Corresponding intrinsic: `_mm_maskmove_si64`

Store the data in `A` to the address `p` without polluting the caches. `A` can be any `Ivec` type.

```
void store_nta(__m64 *p, M64 A);
```
Corresponding intrinsic: `_mm_stream_pi`

Compute the element-wise average of the respective unsigned 8-bit integers in `A` and `B`.

```
Iu8vec8 simd_avg(Iu8vec8 A, Iu8vec8 B);
```
Corresponding intrinsic: `_mm_avg_pu8`

Compute the element-wise average of the respective unsigned 16-bit integers in `A` and `B`.

```
Iu16vec4 simd_avg(Iu16vec4 A, Iu16vec4 B);
```
Corresponding intrinsic: `_mm_avg_pu16`

Conversions between Fvec and Ivec

Convert the lower double-precision floating-point value of `A` to a 32-bit integer with truncation.

```
int F64vec2ToInt(F64vec42 A);
r := (int)A0;
```

Convert the four floating-point values of `A` to two the two least significant double-precision floating-point values.

```
F64vec2 F32vec4ToF64vec2(F32vec4 A);
r0 := (double)A0;
r1 := (double)A1;
```

Convert the two double-precision floating-point values of `A` to two single-precision floating-point values.

```
F32vec4 F64vec2ToF32vec4(F64vec2 A);
r0 := (float)A0;
r1 := (float)A1;
```

Convert the signed `int` in `B` to a double-precision floating-point value and pass the upper double-precision value from `A` through to the result.

```
F64vec2 InttoF64vec2(F64vec2 A, int B);
r0 := (double)B;
r1 := A1;
```

Convert the lower floating-point value of `A` to a 32-bit integer with truncation.

```
int F32vec4ToInt(F32vec4 A);
r := (int)A0;
```

Convert the two lower floating-point values of `A` to two 32-bit integer with truncation, returning the integers in packed form.

```
Is32vec2 F32vec4ToIs32vec2 (F32vec4 A);
r0 := (int)A0;
r1 := (int)A1;
```

Convert the 32-bit integer value `B` to a floating-point value; the upper three floating-point values are passed through from `A`.

```
F32vec4 IntToF32vec4(F32vec4 A, int B);
r0 := (float)B;
r1 := A1;
r2 := A2;
r3 := A3;
```

Convert the two 32-bit integer values in packed form in `B` to two floating-point values; the upper two floating-point values are passed through from `A`.

```
F32vec4 Is32vec2ToF32vec4(F32vec4 A, Is32vec2 B);
r0 := (float)B0;
r1 := (float)B1;
r2 := A2;
r3 := A3;
```

Floating-point Vector Classes

The floating-point vector classes, `F64vec2`, `F32vec4`, and `F32vec1`, provide an interface to SIMD operations. The class specifications are as follows:

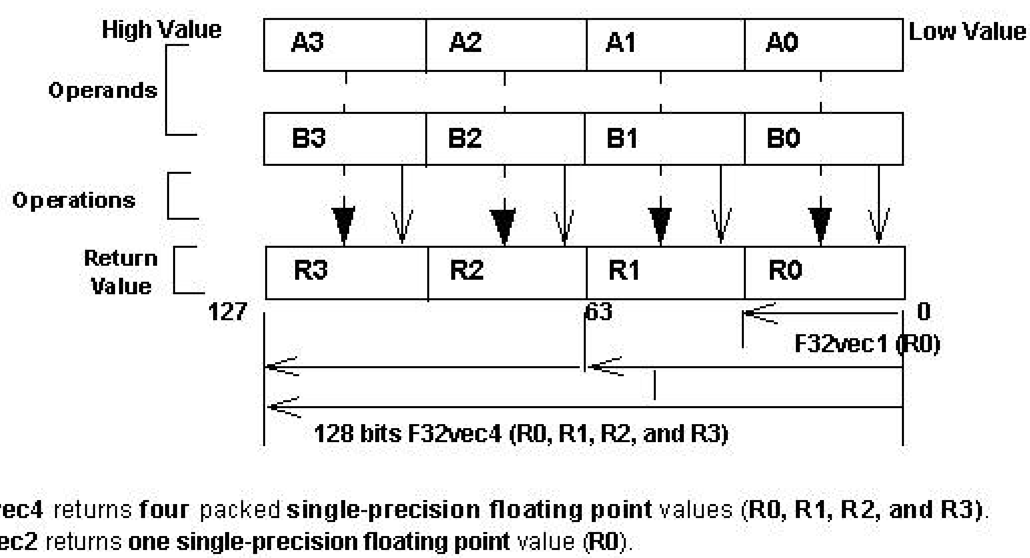
```
F64vec2 A(double x, double y);
```

```
F32vec4 A(float z, float y, float x, float w);
```

```
F32vec1 B(float w);
```

The packed floating-point input values are represented with the right-most value lowest as shown in the following table.

Single-Precision Floating-point Elements



Fvec Syntax and Notation

This reference uses the following conventions for syntax and return values.

Fvec Classes Syntax Notation

Fvec classes use the syntax conventions shown the following examples:

`[Fvec_Class] R = [Fvec_Class] A [operator][Ivec_Class] B;`

Example 1:`F64vec2 R = F64vec2 A & F64vec2 B;`

`[Fvec_Class] R = [operator]([Fvec_Class] A,[Fvec_Class] B);`

Example 2:`F64vec2 R = andnot(F64vec2 A, F64vec2 B);`

`[Fvec_Class] R [operator]= [Fvec_Class] A;`

Example 3:`F64vec2 R &= F64vec2 A;`

where

`[operator]` is an operator (for example, `&`, `|`, `or ^`)

`[Fvec_Class]` is any `Fvec` class (`F64vec2`, `F32vec4`, or `F32vec1`)

`R`, `A`, `B` are declared `Fvec` variables of the type indicated.

Return Value Notation

Because the `Fvec` classes have packed elements, the return values typically follow the conventions presented in the Return Value Convention Notation Mappings table. `F32vec4` returns four single-precision, floating-point values (R0, R1, R2, and R3); `F64vec2` returns two double-precision, floating-point values, and `F32vec1` returns the lowest single-precision floating-point value (R0).

Return Value Convention Notation Mappings

Example 1:	Example 2:	Example 3:	F32vec 4	F64vec 2	F32vec 1
`R0 := A0 & B0;`	`R0 := A0 andnot B0;`	`R0 &= A0;`	x	x	x
`R1 := A1 & B1;`	`R1 := A1 andnot B1;`	`R1 &= A1;`	x	x	N/A
`R2 := A2 & B2;`	`R2 := A2 andnot B2;`	`R2 &= A2;`	x	N/A	N/A
`R3 := A3 & B3`	`R3 := A3 andhot B3;`	`R3 &= A3;`	x	N/A	N/A

Data Alignment

Memory operations using the Intel® Streaming SIMD Extensions should be performed on 16-byte-aligned data whenever possible. Memory operations using the Intel® Advanced Vector Extensions should be performed on 32-byte-aligned data whenever possible.

`F32vec4` and `F64vec2` object variables are properly aligned by default. Note that floating point arrays are not automatically aligned. To get 16-byte alignment, you can use the alignment `__declspec`:

```
__declspec( align(16) ) float A[4];
```

Conversions

All `Fvec` object variables can be implicitly converted to `__m128` data types. For example, the results of computations performed on `F32vec4` or `F32vec1` object variables can be assigned to `__m128` data types.

```
__m128d mm = A & B; /* where A,B are F64vec2 object variables */
__m128 mm = A & B; /* where A,B are F32vec4 object variables */
__m128 mm = A & B; /* where A,B are F32vec1 object variables */
```

Constructors and Initialization

The following table shows how to create and initialize F32vec objects with the Fvec classes.

Constructors and Initialization for Fvec Classes

Example	Intrinsic	Returns
Constructor Declaration		

`F64vec2 A;`
`F32vec4 B;`
`F32vec1 C;`
	N/A	N/A

__m128 Object Initialization		

`F64vec2 A(__m128d mm);`
`F32vec4 B(__m128 mm);`
`F32vec1 C(__m128 mm);`
	N/A	N/A

Double Initialization		

`/* Initializes two doubles. */`
`F64vec2 A(double d0, double d1);`
`F64vec2 A = F64vec2(double d0, double d1);`
	`_mm_set_pd`	A0 := d0;
		A1 := d1;

`F64vec2 A(double d0);`
`/* Initializes both return values`
`with the same double precision value */.`
	`_mm_set1_pd`	A0 := d0;
		A1 := d0;

Float Initialization

`F32vec1 B(int I);` `/* Initializes the lowest value of B with f0, other values are undefined.*/`	`_mm_cvtsi32_ss`	B0 := f0; B1 := {} B2 := {} B3 := {}

Arithmetic Operators

The following table lists the arithmetic operators of the `Fvec` classes and generic syntax. The operators have been divided into standard and advanced operations, which are described in more detail later in this section.

Fvec Arithmetic Operators

Category	Operation	Operators	Generic Syntax
Standard	Addition	`+` `+=`	`R = A + B;` `R += A;`
	Subtraction	`-` `-=`	`R = A - B;` `R -= A;`
	Multiplication	`*` `*=`	`R = A * B;` `R *= A;`
	Division	`/` `/=`	`R = A / B;` `R /= A;`
Advanced	Square Root	`sqrt`	`R = sqrt(A);`
	Reciprocal (Newton-Raphson)	`rcp` `rcp_nr`	`R = rcp(A);` `R = rcp_nr(A);`
	Reciprocal Square Root (Newton-Raphson)	`rsqrt` `rsqrt_nr`	`R = rsqrt(A);` `R = rsqrt_nr(A);`

Standard Arithmetic Operator Usage

The following two tables show the return values for each class of the standard arithmetic operators, which use the syntax styles described earlier in the Return Value Notation section.

Standard Arithmetic Return Value Mapping

R	A	Operators				B	F32vec 4	F64vec 2	F32vec 1
R0:=	A0	+	-	*	/	B0	X	X	X
R1:=	A1	+	-	*	/	B1	X	X	N/A
R2:=	A2	+	-	*	/	B2	X	N/A	N/A
R3:=	A3	+	-	*	/	B3	X	N/A	N/A

Arithmetic with Assignment Return Value Mapping

R	Operators				A	F32vec4	F64vec2	F32vec1
R0:=	+=	-=	*=	/=	A0	X	X	X
R1:=	+=	-=	*=	/=	A1	X	X	N/A
R2:=	+=	-=	*=	/=	A2	X	N/A	N/A
R3:=	+=	-=	*=	/=	A3	X	N/A	N/A

This table lists standard arithmetic operator syntax and intrinsics.

Standard Arithmetic Operations for Fvec Classes

Operation	Returns	Example Syntax Usage	Intrinsic
Addition	4 floats	`F32vec4 R = F32vec4 A + F32vec4 B;` `F32vec4 R += F32vec4 A;`	`_mm_add_ps`
	2 doubles	`F64vec2 R = F64vec2 A + F32vec2 B;` `F64vec2 R += F64vec2 A;`	`_mm_add_pd`
	1 float	`F32vec1 R = F32vec1 A + F32vec1 B;` `F32vec1 R += F32vec1 A;`	`_mm_add_ss`
Subtraction	4 floats	`F32vec4 R = F32vec4 A - F32vec4 B;` `F32vec4 R -= F32vec4 A;`	`_mm_sub_ps`

Operation	Returns	Example Syntax Usage	Intrinsic
	2 doubles	`F64vec2 R - F64vec2 A + F32vec2 B;` `F64vec2 R -= F64vec2 A;`	`_mm_sub_pd`
	1 float	`F32vec1 R = F32vec1 A - F32vec1 B;` `F32vec1 R -= F32vec1 A;`	`_mm_sub_ss`
Multiplication	4 floats	`F32vec4 R = F32vec4 A * F32vec4 B;` `F32vec4 R *= F32vec4 A;`	`_mm_mul_ps`
	2 doubles	`F64vec2 R = F64vec2 A * F364vec2 B;` `F64vec2 R *= F64vec2 A;`	`_mm_mul_pd`
	1 float	`F32vec1 R = F32vec1 A * F32vec1 B;` `F32vec1 R *= F32vec1 A;`	`_mm_mul_ss`
Division	4 floats	`F32vec4 R = F32vec4 A / F32vec4 B;` `F32vec4 R /= F32vec4 A;`	`_mm_div_ps`
	2 doubles	`F64vec2 R = F64vec2 A / F64vec2 B;` `F64vec2 R /= F64vec2 A;`	`_mm_div_pd`
	1 float	`F32vec1 R = F32vec1 A / F32vec1 B;` `F32vec1 R /= F32vec1 A;`	`_mm_div_ss`

Advanced Arithmetic Operator Usage

The following table shows the return values classes of the advanced arithmetic operators, which use the syntax styles described earlier in the Return Value Notation section.

Advanced Arithmetic Return Value Mapping

R	Operators					A	F32vec4	F64vec2	F32vec1
R0:=	`sqrt`	`rcp`	`rsqrt`	`rcp_nr`	`rsqrt_nr`	A0	X	X	X

R	Operators					A	F32vec4	F64vec2	F32vec1
R1:=	sqrt	rcp	rsqrt	rcp_nr	rsqrt_nr	A1	X	X	N/A
R2:=	sqrt	rcp	rsqrt	rcp_nr	rsqrt_nr	A2	X	N/A	N/A
R3:=	sqrt	rcp	rsqrt	rcp_nr	rsqrt_nr	A3	X	N/A	N/A
f :=	add_horizontal			(A0 + A1 + A2 + A3)			X	N/A	N/A
d :=	add_horizontal			(A0 + A1)			N/A	X	N/A

This table shows examples for advanced arithmetic operators.

Advanced Arithmetic Operations for Fvec Classes

Returns	Example Syntax Usage	Intrinsic
Square Root		
4 floats	`F32vec4 R = sqrt(F32vec4 A);`	`_mm_sqrt_ps`
2 doubles	`F64vec2 R = sqrt(F64vec2 A);`	`_mm_sqrt_pd`
1 float	`F32vec1 R = sqrt(F32vec1 A);`	`_mm_sqrt_ss`
Reciprocal		
4 floats	`F32vec4 R = rcp(F32vec4 A);`	`_mm_rcp_ps`
2 doubles	`F64vec2 R = rcp(F64vec2 A);`	`_mm_rcp_pd`
1 float	`F32vec1 R = rcp(F32vec1 A);`	`_mm_rcp_ss`
Reciprocal Square Root		
4 floats	`F32vec4 R = rsqrt(F32vec4 A);`	`_mm_rsqrt_ps`
2 doubles	`F64vec2 R = rsqrt(F64vec2 A);`	`_mm_rsqrt_pd`
1 float	`F32vec1 R = rsqrt(F32vec1 A);`	`_mm_rsqrt_ss`

Reciprocal Newton Raphson		
4 floats	`F32vec4 R = rcp_nr(F32vec4 A);`	`_mm_sub_ps` `_mm_add_ps` `_mm_mul_ps` `_mm_rcp_ps`
2 doubles	`F64vec2 R = rcp_nr(F64vec2 A);`	`_mm_sub_pd` `_mm_add_pd` `_mm_mul_pd` `_mm_rcp_pd`
1 float	`F32vec1 R = rcp_nr(F32vec1 A);`	`_mm_sub_ss` `_mm_add_ss` `_mm_mul_ss` `_mm_rcp_ss`

Reciprocal Square Root Newton Raphson		
4 float	`F32vec4 R = rsqrt_nr(F32vec4 A);`	`_mm_sub_pd` `_mm_mul_pd` `_mm_rsqrt_ps`
2 doubles	`F64vec2 R = rsqrt_nr(F64vec2 A);`	`_mm_sub_pd` `_mm_mul_pd` `_mm_rsqrt_pd`
1 float	`F32vec1 R = rsqrt_nr(F32vec1 A);`	`_mm_sub_ss` `_mm_mul_ss` `_mm_rsqrt_ss`

Horizontal Add		
1 float	`float f = add_horizontal(F32vec4 A);`	`_mm_add_ss` `_mm_shuffle_ss`
1 double	`double d = add_horizontal(F64vec2 A);`	`_mm_add_sd` `_mm_shuffle_sd`

Minimum and Maximum Operators

Compute the minimums of the two double precision floating-point values of `A` and `B`.

```
F64vec2 R = simd_min(F64vec2 A, F64vec2 B)
R0 := min(A0,B0);
R1 := min(A1,B1);
```

Corresponding intrinsic: `_mm_min_pd`

Compute the minimums of the four single precision floating-point values of `A` and `B`.

```
F32vec4 R = simd_min(F32vec4 A, F32vec4 B)
R0 := min(A0,B0);
R1 := min(A1,B1);
R2 := min(A2,B2);
R3 := min(A3,B3);
```

Corresponding intrinsic: `_mm_min_ps`

Compute the minimum of the lowest single precision floating-point values of `A` and `B`.

```
F32vec1 R = simd_min(F32vec1 A, F32vec1 B)
R0 := min(A0,B0);
```
Corresponding intrinsic: `_mm_min_ss`

Compute the maximums of the two double precision floating-point values of `A` and `B`.

```
F64vec2 simd_max(F64vec2 A, F64vec2 B)
R0 := max(A0,B0);
R1 := max(A1,B1);
```
Corresponding intrinsic: `_mm_max_pd`

Compute the maximums of the four single precision floating-point values of `A` and `B`.

```
F32vec4 R = simd_man(F32vec4 A, F32vec4 B)
R0 := max(A0,B0);
R1 := max(A1,B1);
R2 := max(A2,B2);
R3 := max(A3,B3);
```
Corresponding intrinsic: `_mm_max_ps`

Compute the maximum of the lowest single precision floating-point values of `A` and `B`.

```
F32vec1 simd_max(F32vec1 A, F32vec1 B)
R0 := max(A0,B0);
```
Corresponding intrinsic: `_mm_max_ss`

Logical Operators

The following table lists the logical operators of the Fvec classes and generic syntax. The logical operators for `F32vec1` classes use only the lower 32 bits.

Fvec Logical Operators Return Value Mapping

Bitwise Operation	Operators	Generic Syntax
AND	`&` `&=`	`R = A & B;` `R &= A;`
OR	`|` `|=`	`R = A | B;` `R |= A;`
XOR	`^` `^=`	`R = A ^ B;` `R ^= A;`
andnot	`andnot`	`R = andnot(A);`

The following table lists standard logical operators syntax and corresponding intrinsics. Note that there is no corresponding scalar intrinsic for the `F32vec1` classes, which accesses the lower 32 bits of the packed vector intrinsics.

Logical Operations for Fvec Classes

Operation	Returns	Example Syntax Usage	Intrinsic
AND	4 floats	`F32vec4 & = F32vec4 A & F32vec4 B;` `F32vec4 & &= F32vec4 A;`	`_mm_and_ps`
	2 doubles	`F64vec2 R = F64vec2 A & F64vec2 B;`	`_mm_and_pd`

Operation	Returns	Example Syntax Usage	Intrinsic
		F64vec2 R &= F64vec2 A;	
	1 float	F32vec1 R = F32vec1 A & F32vec1 B; F32vec1 R &= F32vec1 A;	_mm_and_ps
OR	4 floats	F32vec4 R = F32vec4 A | F32vec4 B; F32vec4 R |= F32vec4 A;	_mm_or_ps
	2 doubles	F64vec2 R = F64vec2 A | F64vec2 B; F64vec2 R |= F64vec2 A;	_mm_or_pd
	1 float	F32vec1 R = F32vec1 A | F32vec1 B; F32vec1 R |= F32vec1 A;	_mm_or_ps
XOR	4 floats	F32vec4 R = F32vec4 A ^ F32vec4 B; F32vec4 R ^= F32vec4 A;	_mm_xor_ps
	2 doubles	F64vec2 R = F64vec2 A ^ F64vec2 B; F64vec2 R ^= F64vec2 A;	_mm_xor_pd
	1 float	F32vec1 R = F32vec1 A ^ F32vec1 B; F32vec1 R ^= F32vec1 A;	_mm_xor_ps
ANDNOT	2 doubles	F64vec2 R = andnot(F64vec2 A, F64vec2 B);	_mm_andnot_pd

Compare Operators

The operators described in this section compare the single precision floating-point values of A and B. Comparison between objects of any Fvec class return the same class being compared.

The following table lists the compare operators for the Fvec classes.

Compare Operators and Corresponding Intrinsics

Compare For:	Operators	Syntax
Equality	cmpeq	R = cmpeq(A, B)
Inequality	cmpneq	R = cmpneq(A, B)

Compare For:	Operators	Syntax
Greater Than	`cmpgt`	`R = cmpgt(A, B)`
Greater Than or Equal To	`cmpge`	`R = cmpge(A, B)`
Not Greater Than	`cmpngt`	`R = cmpngt(A, B)`
Not Greater Than or Equal To	`cmpnge`	`R = cmpnge(A, B)`
Less Than	`cmplt`	`R = cmplt(A, B)`
Less Than or Equal To	`cmple`	`R = cmple(A, B)`
Not Less Than	`cmpnlt`	`R = cmpnlt(A, B)`
Not Less Than or Equal To	`cmpnle`	`R = cmpnle(A, B)`

Compare Operators

The mask is set to `0xffffffff` for each floating-point value where the comparison is true and `0x00000000` where the comparison is false. The following table shows the return values for each class of the compare operators, which use the syntax described earlier in the Return Value Notation section.

Compare Operator Return Value Mapping

R	A0	For Any Operators	B	If True	If False	F32vec 4	F64vec 2	F32vec 1
R0 :=	(A1 !(A1	cmp[eq | lt | le | gt | ge] cmp[ne | nlt | nle | ngt | nge]	B1) B1)	0xffffffff	0x0000000	X	X	X
R1 :=	(A1 !(A1	cmp[eq | lt | le | gt | ge] cmp[ne | nlt | nle | ngt | nge]	B2) B2)	0xffffffff	0x0000000	X	X	N/A
R2 :=	(A1 !(A1	cmp[eq | lt | le | gt | ge] cmp[ne | nlt | nle | ngt | nge]	B3) B3)	0xffffffff	0x0000000	X	N/A	N/A
R3 :=	A3	cmp[eq | lt | le | gt | ge] cmp[ne | nlt | nle | ngt | nge]	B3) B3)	0xffffffff	0x0000000	X	N/A	N/A

The following table shows examples for arithmetic operators and intrinsics.

Compare Operations for Fvec Classes

Returns	Example Syntax Usage	Intrinsic
Compare for Equality		
4 floats	`F32vec4 R = cmpeq(F32vec4 A);`	`_mm_cmpeq_ps`
2 doubles	`F64vec2 R = cmpeq(F64vec2 A);`	`_mm_cmpeq_pd`
1 float	`F32vec1 R = cmpeq(F32vec1 A);`	`_mm_cmpeq_ss`
Compare for Inequality		
4 floats	`F32vec4 R = cmpneq(F32vec4 A);`	`_mm_cmpneq_ps`
2 doubles	`F64vec2 R = cmpneq(F64vec2 A);`	`_mm_cmpneq_pd`
1 float	`F32vec1 R = cmpneq(F32vec1 A);`	`_mm_cmpneq_ss`
Compare for Less Than		
4 floats	`F32vec4 R = cmplt(F32vec4 A);`	`_mm_cmplt_ps`
2 doubles	`F64vec2 R = cmplt(F64vec2 A);`	`_mm_cmplt_pd`
1 float	`F32vec1 R = cmplt(F32vec1 A);`	`_mm_cmplt_ss`
Compare for Less Than or Equal		
4 floats	`F32vec4 R = cmple(F32vec4 A);`	`_mm_cmple_ps`
2 doubles	`F64vec2 R = cmple(F64vec2 A);`	`_mm_cmple_pd`
1 float	`F32vec1 R = cmple(F32vec1 A);`	`_mm_cmple_pd`
Compare for Greater Than		
4 floats	`F32vec4 R = cmpgt(F32vec4 A);`	`_mm_cmpgt_ps`
2 doubles	`F64vec2 R = cmpgt(F32vec42 A);`	`_mm_cmpgt_pd`
1 float	`F32vec1 R = cmpgt(F32vec1 A);`	`_mm_cmpgt_ss`

Compare for Greater Than or Equal To		
4 floats	`F32vec4 R = cmpge(F32vec4 A);`	`_mm_cmpge_ps`
2 doubles	`F64vec2 R = cmpge(F64vec2 A);`	`_mm_cmpge_pd`
1 float	`F32vec1 R = cmpge(F32vec1 A);`	`_mm_cmpge_ss`

Compare for Not Less Than		
4 floats	`F32vec4 R = cmpnlt(F32vec4 A);`	`_mm_cmpnlt_ps`
2 doubles	`F64vec2 R = cmpnlt(F64vec2 A);`	`_mm_cmpnlt_pd`
1 float	`F32vec1 R = cmpnlt(F32vec1 A);`	`_mm_cmpnlt_ss`

Compare for Not Less Than or Equal		
4 floats	`F32vec4 R = cmpnle(F32vec4 A);`	`_mm_cmpnle_ps`
2 doubles	`F64vec2 R = cmpnle(F64vec2 A);`	`_mm_cmpnle_pd`
1 float	`F32vec1 R = cmpnle(F32vec1 A);`	`_mm_cmpnle_ss`

Compare for Not Greater Than		
4 floats	`F32vec4 R = cmpngt(F32vec4 A);`	`_mm_cmpngt_ps`
2 doubles	`F64vec2 R = cmpngt(F64vec2 A);`	`_mm_cmpngt_pd`
1 float	`F32vec1 R = cmpngt(F32vec1 A);`	`_mm_cmpngt_ss`

Compare for Not Greater Than or Equal		
4 floats	`F32vec4 R = cmpnge(F32vec4 A);`	`_mm_cmpnge_ps`
2 doubles	`F64vec2 R = cmpnge(F64vec2 A);`	`_mm_cmpnge_pd`
1 float	`F32vec1 R = cmpnge(F32vec1 A);`	`_mm_cmpnge_ss`

Conditional Select Operators for Fvec Classes

Each conditional function compares single-precision floating-point values of A and B. The C and D parameters are used for return value. Comparison between objects of any Fvec class returns the same class.

Conditional Select Operators for Fvec Classes

Conditional Select for:	Operators	Syntax
Equality	`select_eq`	`R = select_eq(A, B)`
Inequality	`select_neq`	`R = select_neq(A, B)`
Greater Than	`select_gt`	`R = select_gt(A, B)`
Greater Than or Equal To	`select_ge`	`R = select_ge(A, B)`
Not Greater Than	`select_gt`	`R = select_gt(A, B)`
Not Greater Than or Equal To	`select_ge`	`R = select_ge(A, B)`
Less Than	`select_lt`	`R = select_lt(A, B)`
Less Than or Equal To	`select_le`	`R = select_le(A, B)`
Not Less Than	`select_nlt`	`R = select_nlt(A, B)`
Not Less Than or Equal To	`select_nle`	`R = select_nle(A, B)`

Conditional Select Operator Usage

For conditional select operators, the return value is stored in C if the comparison is true or in D if false. The following table shows the return values for each class of the conditional select operators, using the Return Value Notation described earlier.

Compare Operator Return Value Mapping

<table>
<tr><th>R</th><th>A0</th><th>Operators</th><th>B</th><th>C</th><th>D</th><th>F32vec4</th><th>F64vec2</th><th>F32vec1</th></tr>

R	A0	Operators	B	C	D	F32vec4	F64vec2	F32vec1
		`select_[ne | nlt | nle | ngt | nge]`						

The following table shows examples for conditional select operations and corresponding intrinsics.

Conditional Select Operations for Fvec Classes

Returns	Example Syntax Usage	Intrinsic
Compare for Equality		
4 floats	`F32vec4 R = select_eq(F32vec4 A);`	`_mm_cmpeq_ps`
2 doubles	`F64vec2 R = select_eq(F64vec2 A);`	`_mm_cmpeq_pd`
1 float	`F32vec1 R = select_eq(F32vec1 A);`	`_mm_cmpeq_ss`
Compare for Inequality		
4 floats	`F32vec4 R = select_neq(F32vec4 A);`	`_mm_cmpneq_ps`
2 doubles	`F64vec2 R = select_neq(F64vec2 A);`	`_mm_cmpneq_pd`
1 float	`F32vec1 R = select_neq(F32vec1 A);`	`_mm_cmpneq_ss`
Compare for Less Than		
4 floats	`F32vec4 R = select_lt(F32vec4 A);`	`_mm_cmplt_ps`
2 doubles	`F64vec2 R = select_lt(F64vec2 A);`	`_mm_cmplt_pd`
1 float	`F32vec1 R = select_lt(F32vec1 A);`	`_mm_cmplt_ss`
Compare for Less Than or Equal		
4 floats	`F32vec4 R = select_le(F32vec4 A);`	`_mm_cmple_ps`
2 doubles	`F64vec2 R = select_le(F64vec2 A);`	`_mm_cmple_pd`
1 float	`F32vec1 R = select_le(F32vec1 A);`	`_mm_cmple_ps`

Compare for Greater Than		
4 floats	F32vec4 R = select_gt(F32vec4 A);	_mm_cmpgt_ps
2 doubles	F64vec2 R = select_gt(F64vec2 A);	_mm_cmpgt_pd
1 float	F32vec1 R = select_gt(F32vec1 A);	_mm_cmpgt_ss

Compare for Greater Than or Equal To		
4 floats	F32vec1 R = select_ge(F32vec4 A);	_mm_cmpge_ps
2 doubles	F64vec2 R = select_ge(F64vec2 A);	_mm_cmpge_pd
1 float	F32vec1 R = select_ge(F32vec1 A);	_mm_cmpge_ss

Compare for Not Less Than		
4 floats	F32vec1 R = select_nlt(F32vec4 A);	_mm_cmpnlt_ps
2 doubles	F64vec2 R = select_nlt(F64vec2 A);	_mm_cmpnlt_pd
1 float	F32vec1 R = select_nlt(F32vec1 A);	_mm_cmpnlt_ss

Compare for Not Less Than or Equal		
4 floats	F32vec1 R = select_nle(F32vec4 A);	_mm_cmpnle_ps
2 doubles	F64vec2 R = select_nle(F64vec2 A);	_mm_cmpnle_pd
1 float	F32vec1 R = select_nle(F32vec1 A);	_mm_cmpnle_ss

Compare for Not Greater Than		
4 floats	F32vec1 R = select_ngt(F32vec4 A);	_mm_cmpngt_ps
2 doubles	F64vec2 R = select_ngt(F64vec2 A);	_mm_cmpngt_pd
1 float	F32vec1 R = select_ngt(F32vec1 A);	_mm_cmpngt_ss

Compare for Not Greater Than or Equal		
4 floats	`F32vec1 R = select_nge(F32vec4 A);`	`_mm_cmpnge_ps`
2 doubles	`F64vec2 R = select_nge(F64vec2 A);`	`_mm_cmpnge_pd`
1 float	`F32vec1 R = select_nge(F32vec1 A);`	`_mm_cmpnge_ss`

Cacheability Support Operators

Stores (non-temporal) the two double-precision, floating-point values of `A`. Requires a 16-byte aligned address.

`void store_nta(double *p, F64vec2 A);`
Corresponding intrinsic: `_mm_stream_pd`

Stores (non-temporal) the four single-precision, floating-point values of `A`. Requires a 16-byte aligned address.

`void store_nta(float *p, F32vec4 A);`
Corresponding intrinsic: `_mm_stream_ps`

Debug Operations

The debug operations do not map to any compiler intrinsics for MMX™ technology or Intel® Streaming SIMD Extensions . They are provided for debugging programs only. Use of these operations may result in loss of performance, so you should not use them outside of debugging.

Output Operations

The two single, double-precision floating-point values of `A` are placed in the output buffer and printed in decimal format as follows:

```
cout << F64vec2 A;
"[1]:A1 [0]:A0"
```

Corresponding intrinsics: none

The four, single-precision floating-point values of `A` are placed in the output buffer and printed in decimal format as follows:

```
cout << F32vec4 A;
"[3]:A3 [2]:A2 [1]:A1 [0]:A0"
```

Corresponding intrinsics: none

The lowest, single-precision floating-point value of `A` is placed in the output buffer and printed.

`cout << F32vec1 A;`
Corresponding intrinsics: none

Element Access Operations

```
double d = F64vec2 A[int i]
```

Read one of the two, double-precision floating-point values of `A` without modifying the corresponding floating-point value. Permitted values of `i` are 0 and 1. For example:

If DEBUG is enabled and `i` is not one of the permitted values (0 or 1), a diagnostic message is printed and the program aborts.

```
double d = F64vec2 A[1];
```
Corresponding intrinsics: none

Read one of the four, single-precision floating-point values of `A` without modifying the corresponding floating point value. Permitted values of `i` are 0, 1, 2, and 3. For example:

```
float f = F32vec4 A[int i]
```

If DEBUG is enabled and `i` is not one of the permitted values (0-3), a diagnostic message is printed and the program aborts.

```
float f = F32vec4 A[2];
```
Corresponding intrinsics: none

Element Assignment Operations

```
F64vec4 A[int i] = double d;
```

Modify one of the two, double-precision floating-point values of `A`. Permitted values of `int i` are 0 and 1. For example:

```
F32vec4 A[1] = double d;
F32vec4 A[int i] = float f;
```

Modify one of the four, single-precision floating-point values of `A`. Permitted values of `int i` are 0, 1, 2, and 3. For example:

If DEBUG is enabled and `int i` is not one of the permitted values (0-3), a diagnostic message is printed and the program aborts.

```
F32vec4 A[3] = float f;
```
Corresponding intrinsics: none.

Load and Store Operators

Loads two, double-precision floating-point values, copying them into the two, floating-point values of `A`. No assumption is made for alignment.

```
void loadu(F64vec2 A, double *p)
```
Corresponding intrinsic: `_mm_loadu_pd`

Stores the two, double-precision floating-point values of `A`. No assumption is made for alignment.

```
void storeu(float *p, F64vec2 A);
```
Corresponding intrinsic: `_mm_storeu_pd`

Loads four, single-precision floating-point values, copying them into the four floating-point values of `A`. No assumption is made for alignment.

```
void loadu(F32vec4 A, double *p)
```
Corresponding intrinsic: `_mm_loadu_ps`

Stores the four, single-precision floating-point values of `A`. No assumption is made for alignment.

```
void storeu(float *p, F32vec4 A);
```
Corresponding intrinsic: `_mm_storeu_ps`

Unpack Operators

Selects and interleaves the lower, double-precision floating-point values from `A` and `B`.

```
F64vec2 R = unpack_low(F64vec2 A, F64vec2 B);
```
Corresponding intrinsic: `_mm_unpacklo_pd(a, b)`

Selects and interleaves the higher, double-precision floating-point values from `A` and `B`.

`F64vec2 R = unpack_high(F64vec2 A, F64vec2 B);`
Corresponding intrinsic: `_mm_unpackhi_pd(a, b)`

Selects and interleaves the lower two, single-precision floating-point values from `A` and `B`.

`F32vec4 R = unpack_low(F32vec4 A, F32vec4 B);`
Corresponding intrinsic: `_mm_unpacklo_ps(a, b)`

Selects and interleaves the higher two, single-precision floating-point values from `A` and `B`.

`F32vec4 R = unpack_high(F32vec4 A F32vec4 B);`
Corresponding intrinsic: `_mm_unpackhi_ps(a, b)`

Move Mask Operators

Creates a 2-bit mask from the most significant bits of the two, double-precision floating-point values of `A`, as follows:

```
int i = move_mask(F64vec2 A)
i := sign(a1)<<1 | sign(a0)<<0
```
Corresponding intrinsic: `_mm_movemask_pd`

Creates a 4-bit mask from the most significant bits of the four, single-precision floating-point values of `A`, as follows:

```
int i = move_mask(F32vec4 A)
i := sign(a3)<<3 | sign(a2)<<2 | sign(a1)<<1 | sign(a0)<<0
```
Corresponding intrinsic: `_mm_movemask_ps`

Classes Quick Reference

This appendix contains tables listing operators to perform various SIMD operations, corresponding intrinsics to perform those operations, and the classes that implement those operations. The classes listed here belong to the Intel® C++ Class Libraries for SIMD Operations.

In the following tables,

- N/A indicates that the operator is not implemented in that particular class. For example, in the Logical Operations table, the `Andnot` operator is not implemented in the `F32vec4` and `F32vec1` classes.
- All other entries under Classes indicate that those operators are implemented in those particular classes, and the entries under the Classes columns provide the suffix for the corresponding intrinsic. For example, consider the Arithmetic Operations: Part1 table, where the corresponding intrinsic is `_mm_add_[x]` and the entry `epi16` is under the `I16vec8` column. It means that the `I16vec8` class implements the addition operators and the corresponding intrinsic is `_mm_add_epi16`.

Logical Operations:

F32vec4ToIs32vec2	_mm_cvttps_pi32
IntToF32vec4	_mm_cvtsi32_ss
Is32vec2ToF32vec4	_mm_cvtpi32_ps

Programming Example

This sample program uses the `F32vec4` class to average the elements of a twenty element floating point array.

```
//Include Intel® Streaming SIMD Extension (Intel® SSE) Class Definitions
 #include <fvec.h>

//Shuffle any two single precision floating point from a
//into low two SP FP and shuffle any two SP FP from b
//into high two SP FP of destination

#define SHUFFLE(a,b,i) (F32vec4)_mm_shuffle_ps(a,b,i)
#include <stdio.h>
#define SIZE 20

//Global variables
 float result;
_MM_ALIGN16 float array[SIZE];

//*****************************************************
// Function: Add20ArrayElements
// Add all the elements of a twenty element array
//*****************************************************
void Add20ArrayElements (F32vec4 *array, float *result) {
   F32vec4 vec0, vec1;
   vec0 = _mm_load_ps ((float *) array); // Load array's first four floats

   //*****************************************************
   // Add all elements of the array, four elements at a time
   //******************************************************
   vec0 += array[1]; // Add elements 5-8
   vec0 += array[2]; // Add elements 9-12
   vec0 += array[3]; // Add elements 13-16
   vec0 += array[4]; // Add elements 17-20

   //*****************************************************
   // There are now four partial sums.
```

```
   // Add the two lowers to the two raises,
   // then add those two results together
   //*****************************************************
   vec1 = SHUFFLE(vec1, vec0, 0x40);
   vec0 += vec1;
   vec1 = SHUFFLE(vec1, vec0, 0x30);
   vec0 += vec1;
   vec0 = SHUFFLE(vec0, vec0, 2);
   _mm_store_ss (result, vec0); // Store the final sum
}

void main(int argc, char *argv[]) {
   int i;

//Initialize the array
   for (i=0; i < SIZE; i++) { array[i] = (float) i; }

//Call function to add all array elements
   Add20ArrayElements (array, &result);

//Print average array element value
   printf ("Average of all array values = %f\n", result/20.);
   printf ("The correct answer is %f\n\n\n", 9.5);
}
```

Intel's valarray Implementation

The Intel® C++ Compiler Classic provides a high performance implementation of specialized one-dimensional valarray operations for the C++ standard STL valarray container.

The standard C++ valarray template consists of array/vector operations for high performance computing. These operations are designed to exploit high performance hardware features such as parallelism and achieve performance benefits.

Intel's valarray implementation uses the Intel® Integrated Performance Primitives (Intel® IPP), which is part of the product. Select IPP when you install the product.

The valarray implementation consists of a replacement header, `<valarray>`, that provides a specialized, high-performance implementation for the following operators and types:

Operator	Type
abs, acos, acosh, asin, asinh, atan, atan2, atanh, cbrt, cdfnorm, ceil, cos, cosh, erf, erfc, erfinv, exp, expm1, floor, hypot, inv, invcbrt, invsqrt, ln, log, log10, log1p, nearbyint, pow, pow2o3, pow3o2, powx, rint, round, sin, sinh, sqrt, tan, tanh, trunk	float, double
add, conj, div, mul, mulbyconj, mul, sub	Ipp32fc, Ipp64fc
addition, subtraction, division, multiplication	float, double
bitwise or, and, xor	(all unsigned) char, short, int
min, max, sum	signed or short/signed int, float, double

Use valarray in Source Code

Intel's valarray implementation allows you to declare huge arrays for parallel processing. Improved implementation of valarray is tied up with calling the IPP libraries that are part of Intel® Integrated Performance Primitives (Intel® IPP).

To use valarrays in your source code, include the valarray header file, `<valarray>`. The `<valarray>` header file is located in the path `<installdir>/perf_header`.

The following example shows a valarray addition operation (+) specialized through use of Intel's implementation of valarray:

```
#include <valarray>
void test( )
{
    std::valarray<float> vi(N), va(N);
    …
    vi = vi + va;  //array addition
    …
}
```

NOTE
To use the static merged library containing all CPU-specific optimized versions of the library code, you need to call the `ippStaticInit` function first, before any IPP calls. This ensures automatic dispatch to the appropriate version of the library code for Intel® processor and the generic version of the library code for non-Intel processors at runtime. If you do not call `ippStaticInit` first, the merged library will use the generic instance of the code. If you are using the dynamic version of the libraries, you do not need to call `ippStaticInit`.

Compiling valarray Source Code

To compile your valarray source code, the compiler option, `/Quse-intel-optimized-headers` (for Windows*) or `-use-intel-optimized-headers` (for Linux* and macOS), is used to include the required valarray header file and all the necessary IPP library files.

The following examples illustrate how to compile and link a program to include the Intel valarray replacement header file and link with the Intel® IPP libraries. Refer to the Intel® IPP documentation for details.

In the following examples, "merged" libraries refers to using a static library that contains all the CPU-specific variants of the library code.

Linux* OS Examples

The following command line performs a one-step compilation for a system based on Intel® 64 architecture, running Linux OS:

```
icpc -use-intel-optimized-headers source.cpp
```

The following command lines perform separate compile and link steps for a system based on Intel® 64 architecture, running Linux OS:

so (dynamic):

```
icpc -use-intel-optimized-headers -c source.cpp
```

```
icpc source.o -use-intel-optimized-headers -shared-intel
```

Merged (static):

```
icpc -use-intel-optimized-headers -c source.cpp
```

```
icpc source.o -use-intel-optimized-headers
```

Windows* OS Examples

The following command line performs a one-step compilation for a system based on IA-32 architecture, running Windows OS:

```
icc /Quse-intel-optimized-headers source.cpp
```

The following command lines perform separate compile and link steps for a system based on IA-32 architecture, running Windows OS:

DLL (dynamic):

```
icc /Quse-intel-optimized-headers /c source.cpp
```

```
icc source.obj /Quse-intel-optimized-headers
```

Merged (static):

```
icc /Quse-intel-optimized-headers /Qipp-link:static /c source.cpp

Intel's C++ Asynchronous I/O Extensions for Windows

Intel's C/C++ asynchronous input/output (Intel's C/C++ AIO) extensions, like library functions or classes, can be used to improve the performance of C/C++ applications by executing I/O operations in asynchronous mode. The extensions initiate I/O operation and immediately resume normal tasks while the I/O operations are executed in parallel.

Intel's C/C++ asynchronous I/O extensions are supported on IA-32 architecture-based and Intel® 64 architecture-based Windows platforms.

Intel's C/C++ AIO library functions and template class are implemented in the `libicaio.lib` library. This library is supplied as part of the Intel® C++ Compiler Classic package and is installed into the common directory: `<install-dir>/lib`.

Types of Intel's C/C++ Asynchronous I/O Extensions

Intel's C/C++ asynchronous I/O extensions comprise the following:

- **Asynchronous I/O Library:** A set of POSIX-based asynchronous I/O library functions, supported on Windows operating systems, for applications written in C/C++ language. The interface file is `aio.h`.
- **Asynchronous I/O Template Class:** An `asych_class` template class, supported on Windows operating systems, for applications written in C++ language. This template class can be used to introduce asynchronous execution of I/O operations with the Standard Template Library's (STL's) streams classes. The interface file is `aiostream.h`.

Intel's C++ Asynchronous I/O Library for Windows

Intel's C/C++ asynchronous I/O (AIO) library implementation for the Windows operating system (on IA-32 and Intel® 64 platforms) is similar to the POSIX AIO library implementation for the Linux operating system.

The differences between Intel's C/C++ AIO Windows OS implementation and the standard POSIX AIO implementation are listed below:

- In `struct aiocb`,
  - The Windows OS compatible type `HANDLE` replaces the POSIX AIO type `unsigned int` for the file descriptor `aio_fildes`.
  - The type `intptr_t` replaces the POSIX AIO types `ssize_t` and `__off_t`.
- The structure specifying the signal event descriptor, `struct sigevent` is similar to the Linux operating system implementation of the POSIX AIO library. It differs from the Linux implementation in the following ways:
  - Signal notification and non-notification for thread call-back is supported
  - Signal notification on completion of the AIO operation is *not* supported

    This is true for programs that were already written for Linux/Unix and ported to Windows OS that wish to setup an AIO completion handler without the name of the handler set in the `aiocb struct`. Because of the way that signals are supported in Windows, this is impossible to implement. For new applications, or to port existing applications, the programmer should set the name of the handler before calling the `aio_read` or `aio_write` routines. For example:

```
static void aio_CompletionRoutine(sigval_t sigval)
{
    // … code …
}

… code …

my_aio.aio_sigevent.sigev_notify          = SIGEV_THREAD;
my_aio.aio_sigevent.sigev_notify_function = aio_CompletionRoutine;
```

> **NOTE**
> The POSIX AIO library and the Microsoft SDK provide similar AIO functions. The main difference between the POSIX AIO functions and the Windows operating system-based AIO functions is that while POSIX allows you to execute AIO operations with any file, the Windows operating system executes AIO operations only with files flagged with `FILE_FLAG_OVERLAPPED`.

Intel's asynchronous I/O library functions listed below are all based on POSIX AIO functions. They are defined in the `aio.h` file.

- `aio_read()`
- `aio_write()`
- `aio_suspend()`
- `aio_error()`
- `aio_return()`
- `aio_fsync()`
- `aio_cancel()`
- `lio_listio()`

aio_read

Performs an asynchronous read operation.

Syntax

`int aio_read(struct aiocb *aiocbp);`

Description

The `aio_read()` function requests an asynchronous read operation, calling the function,

```
"ReadFile(hFile, lpBuffer, nNumberOfBytesToRead, lpNumberOfBytesRead, NULL);"
```

where,

- `hFile` is given by *aiocbp->aio_fildes*
- `lpBuffer` is given by *aiocbp->aio_buf*
- `nNumberOfBytesToRead` is given by *aiocbp->aio_nbytes*

Use the function `aio_return()` to retrieve the actual bytes read in `lpNumberOfBytesRead`.

Use the extension *aiocb->aio_offset == (intptr_t)-1* to start the read operation after the last read record. This extension avoids extra file positioning and enhances performance.

Returns

0: On success

-1: On error

To get the correct error code, use `errno`. To get the error that occurred during asynchronous read operation, use `aio_error()` function.

See Also

Example Code for aio_read()

aio_write

Performs an asynchronous write operation.

Syntax

`int aio_write(struct aiocb *aiocbp);`

Description

The `aio_write()` function requests an asynchronous write operation, calling the function,

```
"WriteFile(hFile, lpBuffer, nNumberOfBytesToWrite, lpNumberOfBytesWritten, NULL);
```

where,

- `hFile` is given by *aiocbp->aio_fildes*
- `lpBuffer` is given by *aiocbp->aio_buf*
- `nNumberOfBytesToWrite` is given by *aiocbp->aio_nbytes*

Use the function `aio_return()` to retrieve the actual bytes written in `lpNumberOfBytesWritten`.

Use the extension *aiocb->aio_offset == (intptr_t)-1* to start the write operation after the last written record. This extension avoids extra file positioning and enhances performance.

Returns

0: On success

-1: On error

To get the correct error code, use `errno`. To get the error that occurred during asynchronous write operation, use `aio_error()` function.

Example Code for aio_write()

Example for aio_read and aio_write Functions

The example illustrates the performance gain of the asynchronous I/O usage in comparison with synchronous I/O usage. In the example, 5.6 MB of data is asynchronously written with the main program computation, which is the scalar multiplication of two vectors with some normalization.

C-source file executing a scalar multiplication:

```
#include <math.h>
#include <stdio.h>
#include <stdlib.h>

double do_compute(double A, double B, int arr_len)
{
  int i;
  double   res = 0;
  double  *xA = malloc(arr_len * sizeof(double));
  double  *xB = malloc(arr_len * sizeof(double));
  if ( !xA || !xB )
   abort();
   for (i = 0; i < arr_len; i++) {
    xA[i] = sin(A);
    xB[i] = cos(B);
    res = res + xA[i]*xA[i];
   }
  free(xA);
  free(xB);
 return res;
}
```

C-main-source file using asynchronous I/O implementation:

```
#define DIM_X   123/*123*/
#define DIM_Y   70000
double  aio_dat[DIM_Y /*12MB*/] = {0};
double  aio_dat_tmp[DIM_Y /*12MB*/];

#include <stdio.h>
#include <aio.h>

typedef struct aiocb  aiocb_t;
   aiocb_t   my_aio;
   aiocb_t  *my_aio_list[1] = {&my_aio};

int main()
{
  double do_compute(double A, double B, int arr_len);
  int i, j;
  HANDLE fd = CreateFile("aio.dat",
  GENERIC_READ | GENERIC_WRITE,
  FILE_SHARE_READ,
  NULL,
  OPEN_ALWAYS,
  FILE_ATTRIBUTE_NORMAL,
  NULL);
/* Do some complex computation */
for (i = 0; i < DIM_X; i++) {
```

```
 for ( j = 0; j < DIM_Y; j++ )
 aio_dat[j] = do_compute(i, j, DIM_X);

  if (i) aio_suspend(my_aio_list, 1, 0);
  my_aio.aio_fildes = fd;
  my_aio.aio_buf    = memcpy(aio_dat_tmp, aio_dat, sizeof(aio_dat_tmp));
  my_aio.aio_nbytes = sizeof(aio_dat_tmp);
  my_aio.aio_offset = (intptr_t)-1;
  my_aio.aio_sigevent.sigev_notify = SIGEV_NONE;

  if ( aio_write((void*)&my_aio) == -1 ) {
  printf("ERROR!!! %s\n", "aio_write()==-1");
  abort();}
  }
 aio_suspend(my_aio_list, 1, 0);
 return 0;
}
```

C-main-source file example 2 using asynchronous I/O implementation:

```
// icx (for C++) dpcpp (for DPC++) -c do_compute.c
// icx (for C++) dpcpp (for DPC++) aio_sample2.c do_compute.obj
// aio_sample2.exe

#define DIM_X   123
#define DIM_Y    70
double  aio_dat[DIM_Y] = {0};
double  aio_dat_tmp[DIM_Y];
static volatile int aio_flg = 1;

#include <aio.h>
typedef struct aiocb  aiocb_t;
aiocb_t               my_aio;
#define WAIT { while (!aio_flg); aio_flg = 0; }
#define aio_OPEN(_fname )\
CreateFile(_fname,                       \
           GENERIC_READ | GENERIC_WRITE, \
           FILE_SHARE_READ,              \
           NULL,                         \
           OPEN_ALWAYS,                  \
           FILE_ATTRIBUTE_NORMAL,        \
           NULL)

static void aio_CompletionRoutine(sigval_t sigval)
{
    aio_flg = 1;
}

int main()
{
    double do_compute(double A, double B, int arr_len);
    int      i, j, res;
    char    *fname = "aio_sample2.dat";
    HANDLE   aio_fildes = aio_OPEN(fname);

    my_aio.aio_fildes = aio_fildes;
    my_aio.aio_nbytes = sizeof(aio_dat_tmp);
    my_aio.aio_sigevent.sigev_notify          = SIGEV_THREAD;
    my_aio.aio_sigevent.sigev_notify_function = aio_CompletionRoutine;
```

```
    /*
    ** writing
    */
    my_aio.aio_offset = -1;
    printf("Writing\n");
    for (i = 0; i < DIM_X; i++) {
        for (j = 0; j < DIM_Y; j++)
            aio_dat[j] = do_compute(i, j, DIM_X);
        WAIT;
        my_aio.aio_buf = memcpy(aio_dat_tmp, aio_dat, sizeof(aio_dat_tmp));
        res = aio_write(&my_aio);
        if (res) {printf("res!=0\n");abort();}
    }

    //
    // flushing
    //
    printf("Flushing\n");
    WAIT;
    res = aio_fsync(O_SYNC, &my_aio);
    if (res) {printf("res!=0\n");abort();}
    WAIT;

    //
    // reading
    //
    printf("Reading\n");
    my_aio.aio_offset = 0;
    my_aio.aio_buf    = (volatile char*)aio_dat_tmp;
    for (i = 0; i < DIM_X; i++) {
        aio_read(&my_aio);
        for (j = 0; j < DIM_Y; j++)
            aio_dat[j] = do_compute(i, j, DIM_X);
        WAIT;
        res = aio_return(&my_aio);
        if (res != sizeof(aio_dat)) {
            printf("aio_read() did read %d bytes, expecting %d bytes\n", res, sizeof(aio_dat));
        }

        for (j = 0; j < DIM_Y; j++)
            if ( aio_dat[j] != aio_dat_tmp[j] )
                {printf("ERROR: aio_dat[j] != aio_dat_tmp[j]\n I=%d J=%d\n", i, j); abort();}
        my_aio.aio_offset += my_aio.aio_nbytes;
    }

    CloseHandle(aio_fildes);

    printf("\nDone\n");

return 0;
}
```

aio_read()

aio_write()

aio_suspend

Suspends the calling process until one of the asynchronous I/O operations completes.

Syntax

```
int aio_suspend(const struct aiocb * const cblist[], int n, const struct timespec
*timeout);
```

Arguments

cblist[]	Pointer to a control block on which I/O is initiated
n	Length of *cblist* list
**timeout*	Time interval to suspend the calling process

Description

The `aio_suspend()` function is like a wait operation. It suspends the calling process until,

- At least one of the asynchronous I/O requests in the list *cblist* of length *n* has completed
- A signal is delivered
- The time interval indicated in *timeout* is not `NULL` and has passed.

Each item in the *cblist* list must either be `NULL` (when it is ignored), or a pointer to a control block on which I/O was initiated using `aio_read()`, `aio_write()`, or `lio_listio()` functions.

Returns

0: On success

-1: On error

To get the correct error code, use `errno`.

See Also

Example Code for aio_suspend()

Example for aio_suspend Function

The following example illustrates a wait operation execution using the `aio_suspend()` function.

```
int aio_ex_2(HANDLE fd)
{
    static struct aiocb   aio[2];
    static struct aiocb  *aio_list[2] = {&aio[0], &aio[1]};
    int i, ret;

/* Data initialization */
IC_AIO_DATA_INIT(aio[0], fd, "rec#1\n", strlen("rec#1\n"), 0)
IC_AIO_DATA_INIT(aio[1], fd, "rec#2\n", strlen("rec#2\n"), aio[0].aio_nbytes)

/* Asynch-write */
if (aio_write(&aio[0]) == -1) return errno;
if (aio_write(&aio[1]) == -1) return errno;

/* Do some complex computation */
printf("do_compute(1000, 1.123)=%f", do_compute(1000, 1.123));

/* do the wait operation using sleep() */
```

```
ret = aio_suspend(aio_list, 2, 0);
if (ret == -1) return errno;

return 0;
}/* aio_ex_2 */
```

Result upon execution:

```
-bash-3.00$ ./a.out
-bash-3.00$ cat dat
rec#1
rec#2
```

Remarks:

1. In the example, the `IC_AIO_DATA_INIT` is defined as follows:

```
#define IC_AIO_DATA_INIT(_aio, _fd, _dat, _len, _off)\
  {memset(&_aio, 0, sizeof(_aio)); \
  _aio.aio_fildes = _fd;          \
  _aio.aio_buf    = _dat;         \
  _aio.aio_nbytes = _len;         \
  _aio.aio_offset = _off;}
```

2. The file descriptor `fd` is obtained as:

```
HANDLE fd = CreateFile("dat",
  GENERIC_READ | GENERIC_WRITE,
  FILE_SHARE_READ,
  NULL,
  OPEN_ALWAYS,
  FILE_ATTRIBUTE_NORMAL/*|FILE_FLAG_OVERLAPPED*/,
  NULL);
```

See Also

aio_suspend()

aio_error

Returns error status for asynchronous I/O requests.

Syntax

`int aio_error(const struct aiocb *aiocbp);`

Arguments

**aiocbp*	Pointer to control block from where asynchronous I/O request is generated

Description

The `aio_error()` function returns the error status for the asynchronous I/O request in the control block, which is pointed to by *aiocbp*.

Returns

EINPROGRESS: When asynchronous I/O request is not completed

ECANCELED: When asynchronous I/O request is cancelled

0: On success

Error value: On error

To get the correct error value/code, use `errno`. This is the same error value returned when an error occurs during a `ReadFile()`, `WriteFile()`, or a `FlushFileBuffers()` operation.

See Also

Example Code for aio_error()

aio_return

Returns the final return status for the asynchronous I/O request.

Syntax

`ssize_t aio_return(struct aiocb *aiocbp);`

Arguments

**aiocbp*	Pointer to control block from where asynchronous I/O request is generated

Description

The `aio_return` function returns the final return status for the asynchronous I/O request with control block pointed to by *aiocbp*.

Call this function only once for any given request, after `aio_error()` returns a value other than *EINPROGRESS*.

Returns

Return value for synchronous ReadFile()/WriteFile()/FlushFileBuffer() requests: When asynchronous I/O operation is completed

Undefined return value: When asynchronous I/O operation is not completed

Error value: When an error occurs

To get the correct error code/value, use `errno`.

See Also

Example Code for aio_return()

Example for aio_error and aio_return Functions

The following example illustrates how the `aio_error()` and `aio_return()` functions can be used.

```
int aio_ex_3(HANDLE fd)
{
 static struct aiocb aio;
 static struct aiocb *aio_list[] = {&aio};
 int    ret;
 char  *dat = "Hello from Ex-3\n";

/* Data initialization and asynchronously writing */

 IC_AIO_DATA_INIT(aio, fd, dat, strlen(dat), 0);
 if (aio_write(& aio) == -1) return errno;

 ret = aio_error(&aio);
 if ( ret == EINPROGRESS ) {
 fprintf(stderr, "ERRNO=%d STR=%s\n", ret, strerror(ret));
```

```
 ret = aio_suspend(aio_list, 1, NULL);
 if (ret == -1) return errno;}
 else if (ret)
 return ret;

 ret = aio_error(&aio);
 if (ret) return ret;

 ret = aio_return(&aio);
 printf("ret=%d\n", ret);

 return 0;
}/* aio_ex_3 */
```

Result upon execution:

```
-bash-3.00$ ./a.out
ERRNO=115 STR=Operation now in progress
ret=16
-bash-3.00$ cat dat
Hello from Ex-3
```

Remarks:

1. In the example, the `IC_AIO_DATA_INIT` is defined as follows:

```
#define IC_AIO_DATA_INIT(_aio, _fd, _dat, _len, _off)\
 {memset(&_aio, 0, sizeof(_aio)); \
 _aio.aio_fildes = _fd;  \
 _aio.aio_buf    = _dat;  \
 _aio.aio_nbytes = _len;  \
 _aio.aio_offset = _off;}
```

2. The file descriptor `fd` is obtained as:

```
HANDLE fd  = CreateFile("dat",
  GENERIC_READ | GENERIC_WRITE,
  FILE_SHARE_READ,
  NULL,
  OPEN_ALWAYS,
  FILE_ATTRIBUTE_NORMAL/*|FILE_FLAG_OVERLAPPED*/,
  NULL);
```

See Also

aio_error()

aio_return()

aio_fsync

Synchronizes all outstanding asynchronous I/O operations.

Syntax

`int aio_fsync(int op, struct aiocb *aiocbp);`

Arguments

op	Type of synchronization request operation

**aiocbp*	Pointer to control block from where asynchronous I/O request is generated

Description

The `aio_fsync()` function performs a synchronization request operation on all outstanding asynchronous I/O operations associated with *aiocbp->aio_fildes*.

Returns

0: On successfully performing a synchronization request.

-1: On error; to get the correct error code, use `errno`.

aio_cancel

Cancels outstanding asynchronous I/O requests for the file descriptor fd.

Syntax

```
int aio_cancel(HANDLE fd, struct aiocb *aiocbp);
```

Arguments

fd	File descriptor
**aiocbp*	Pointer to control block from where asynchronous I/O request is generated

Description

The `aio_cancel()` function cancels outstanding asynchronous I/O requests for the file descriptor *fd*. If *aiocbp* is NULL, all outstanding asynchronous I/O requests are cancelled. If *aiocbp* is not NULL, only the requests described by the control block pointed to by *aiocbp* are cancelled.

Normal asynchronous notification occurs for cancelled requests. The request return status is set to -1, and the request error status is set to ECANCELED. The control block of requests that cannot be cancelled is not changed.

Unspecified results occur if *aiocbp* is not NULL and the *fd* differs from the file descriptor with which the asynchronous operation was initiated.

Returns

AIO_CANCELLED: When all specified requests are cancellled successfully.

AIO_NOTCANCELLED: When at least one of the specified requests is still in process of being cancelled; check the status of request using `aio_error`.

AIO_ALLDONE: When all specified requests were completed before cancel call was placed.

-1: When some error occurs. To get the correct error code, use `errno`.

See Also

Example Code for aio_cancel()

Example for aio_cancel Function

The following example illustrates how `aio_cancel()` function can be used.

```
int aio_ex_4(HANDLE fd)
{
  static struct aiocb   aio;
```

```
  static struct aiocb  *aio_list[] = {&aio};
  int    ret;
  char  *dat = "Hello from Ex-4\n";

 printf("AIO_CANCELED=%d AIO_NOTCANCELED=%d\n",
 AIO_CANCELED,   AIO_NOTCANCELED);

/* Data initialization and asynchronously writing */

 IC_AIO_DATA_INIT(aio, fd, dat, strlen(dat), 0);
 if (aio_write(&aio) == -1) return errno;

 ret = aio_cancel(fd, &aio);
 if ( ret == AIO_NOTCANCELED ) {
 fprintf(stderr, "ERRNO=%d STR=%s\n", ret, strerror(ret));
 ret = aio_suspend(aio_list, 1, NULL);
 if (ret == -1) return errno;}

 ret = aio_cancel(fd, &aio);
 if ( ret == AIO_CANCELED )
 fprintf(stderr, "ERRNO=%d STR=%s\n", ret, strerror(ret));
 else if (ret) return ret;

 return 0;
}/* aio_ex_4 */
```

Result upon execution:

```
-bash-3.00$ ./a.out
AIO_CANCELED=0 AIO_NOTCANCELED=1
ERRNO=1 STR=Operation not permitted
-bash-3.00$ cat dat
Hello from Ex-4
-bash-3.00$
```

Remarks:

1. In the example, the `IC_AIO_DATA_INIT` is defined as follows:

```
#define IC_AIO_DATA_INIT(_aio, _fd, _dat, _len, _off)\
 {memset(&_aio, 0, sizeof(_aio)); \
 _aio.aio_fildes = _fd;          \
 _aio.aio_buf    = _dat;         \
 _aio.aio_nbytes = _len;         \
 _aio.aio_offset = _off;}
```

2. The file descriptor `fd` is obtained as:

```
HANDLE fd = CreateFile("dat",
  GENERIC_READ | GENERIC_WRITE,
  FILE_SHARE_READ,
  NULL,
  OPEN_ALWAYS,
  FILE_ATTRIBUTE_NORMAL/*|FILE_FLAG_OVERLAPPED*/,
  NULL);
```

See Also

aio_cancel()

lio_listio

Performs an asynchronous read operation.

Syntax

```
int lio_listio(int mode, struct aiocb *list[], int nent, struct sigevent *sig);
```

Arguments

mode

Takes following values declared in `<aio.h>` file:

- `LIO_WAIT`: Use when you want the function to return only after completing I/O operations (synchronous I/O operations)
- `LIO_NOWAIT`: Use when you want the function to return as soon as I/O operations are queued (asynchronous I/O requests)

**list[]*

Array of the `aiocb` pointers specifying the submitted I/O requests; NULL elements in the array are ignored

nent

Number of elements in the array

**sig*

Determines if asynchronous notification is sent after all I/O operations completes; takes following values:

- 0: Asynchronous notification occurs; a queued signal, with an application-defined value, is generated when an asynchronous I/O request occurs
- 1: Asynchronous notification does not occur even when asynchronous I/O requests are processed
- 2: Asynchronous notification occurs; a notification function is called to perform notification

Description

The `lio_listio()` function initiates a list of I/O requests with a single function call.

The *mode* argument determines whether the function returns when all the I/O operations are completed, or as soon as the operations are queued.

If the mode argument is `LIO_WAIT`, the function waits until all I/O operations are complete. The *sig* argument is ignored in this case.

If the *mode* argument is `LIO_NOWAIT`, the function returns immediately. Asynchronous notification occurs according to the *sig* argument after all the I/O operations complete.

Returns

When *mode*=`LIO_NOWAIT` the `lio_listio()` function returns:

- **0**: I/O operations are successfully queued
- **-1**: Error; I/O operations not queued; to get the proper error code, use `errno`.

When *mode*=`LIO_WAIT` the `lio_listio()` function returns:

- **0**: I/O operations specified completed successfully
- **-1**: Error; I/O operations not completed; to get the proper error code, use `errno`.

See Also

Example Code for lio_listio()

Example for lio_listio Function

The following example illustrates how the `lio_listio()` function can be used.

```
int aio_ex_5(HANDLE fd)
{
  static struct aiocb   aio[2];
  static struct aiocb  *aio_list[2] = {&aio[0], &aio[1]};
   int               i, ret;

/*
 ** Data initialization and Synchronously writing
*/
 IC_AIO_DATA_INIT(aio[0], fd, "rec#1\n", strlen("rec#1\n"), 0)
 IC_AIO_DATA_INIT(aio[1], fd, "rec#2\n", strlen("rec#2\n"),
 aio[0].aio_nbytes)
 aio[0].aio_lio_opcode = aio[1].aio_lio_opcode = LIO_WRITE;
 ret = lio_listio(LIO_WAIT, aio_list, 2, 0);
 if (ret) return ret;

 return 0;
}/* aio_ex_5 */
```

Result upon execution:

```
-bash-3.00$ ./a.out
-bash-3.00$ cat dat
rec#1
rec#2
-bash-3.00$
```

Remarks:

1. In the example, the `IC_AIO_DATA_INIT` is defined as follows:

```
#define IC_AIO_DATA_INIT(_aio, _fd, _dat, _len, _off)\
  {memset(&_aio, 0, sizeof(_aio)); \
   _aio.aio_fildes = _fd;          \
   _aio.aio_buf    = _dat;         \
   _aio.aio_nbytes = _len;         \
   _aio.aio_offset = _off;}
```

2. The file descriptor `fd` is obtained as:

```
HANDLE fd = CreateFile("dat",
   GENERIC_READ | GENERIC_WRITE,
   FILE_SHARE_READ,
   NULL,
   OPEN_ALWAYS,
   FILE_ATTRIBUTE_NORMAL/*|FILE_FLAG_OVERLAPPED*/,
   NULL);
```

3. The `aio_lio_opcode` refers to the field of each `aiocb` structure that specifies the operation to be performed. The supported operations are `LIO_READ` (do a 'read' operation), `LIO_WRITE` (do a 'write' operation), and `LIO_NOP` (do no operation); these symbols are defined in `<aio.h>`.

Asynchronous I/O Function Errors

This topic only applies to Windows* OS.

The `errno` macro is used to obtain the errors that occur during asynchronous request functions such as `aio_read()`, `aio_write()`, `aio_fsync()`, and `lio_listio()` or asynchronous control functions, such as `aio_cancel()`, `aio_error()`, `aio_return()`, and `aio_suspend()`.

The following example illustrates how `errno` can be used.

```
#include <stdio.h>
#include <stdlib.h>
#include <aio.h>

struct aiocb    my_aio;
struct aiocb   *my_aio_list[1] = {&my_aio};

int main()
{
  int   res;
  double  arr[123456];
 timespec_t   my_t = {1, 0};

/* Data initialization */
 my_aio.aio_fildes = CreateFile("dat",
   GENERIC_READ | GENERIC_WRITE,
   FILE_SHARE_READ,
   NULL,
   OPEN_ALWAYS,
   FILE_ATTRIBUTE_NORMAL,
   NULL);
 my_aio.aio_buf    = (volatile char *)arr;
 my_aio.aio_nbytes = sizeof(arr);

/* Do asynchronous writing with computation overlapping */
 aio_write(&my_aio);
 do_compute(arr, 123456);

/* Suspend the asynchronous writing for 1 sec */
 res = aio_suspend(my_aio_list, 1, &my_t);
 if ( res ) {

/* The call was ended by timeout, before the indicated operations had completed. */
  if ( errno == EAGAIN ) {
  res = aio_suspend(my_aio_list, 1, 0);
  if ( res ) {
  printf("aio_suspend returned non-0\n"); return errno;}
  }
  else
  if ( res ) {
  printf("aio_suspend returned neither 0 nor EAGAIN\n");
  return errno;
  }
 }

 CloseHandle(my_aio.aio_fildes);
 printf("\nPass\n");
```

```
 return 0;
}
```

In the example, the program executes an asynchronous write operation, using `aio_write()`, overlapping with some computation, the `do_compute()` function execution. The pending write operation is suspended for one second using `aio_suspend()`.

On successful execution of the asynchronous write operation, zero is returned. `EAGAIN` or any other error value is returned when the call is ended by timeout before the indicated operation has completed.

You can check `EAGAIN` using the `errno` macro.

Intel's C++ Asynchronous I/O Class for Windows* Operating Systems

This topic only applies to Windows* OS.

Intel's C++ asynchronous I/O template class, `async_class`, is an implementation for the Windows* operating system on IA-32 and Intel® 64 architectures.

The `async_class` template class allows users to perform I/O operations asynchronously to the main program thread. In particular, the `async_class` template class can be used to introduce asynchronous execution of I/O operations with the STL streams classes. Users can quickly switch any of the I/O operations of the STL streams to asynchronous mode with minimal changes to the application code.

The template class `async_class` is defined in the `aiostream.h` file.

Details of template class async_class

Template Class async_class

This topic only applies to Windows* OS.

Intel's C++ asynchronous I/O class implementation contains two main classes within the `async` namespace: the `async_class` template class and the `thread_control` base class.

The header/typedef definitions are as follows:

```
namespace async {

template<class A>
class async_class:
public thread_control, public A
}
```

The template class `async_class` inherits support for asynchronous execution of I/O operations that are integrated within the base `thread_control` class.

All functionality to control asynchronous execution of a queue of STL stream operations is encapsulated in the base class `thread_control` and is inherited by template class `async_class`.

In most cases it is enough to add the header file `aiostream.h` to the source file and declare the file object as an instance of the new template class `async:async_class`. The initial stream class must be the parameter for the template class. Consequently, the defined output operator << and input operator >> are executed asynchronously.

NOTE
The header file `aiostream.h` includes all necessary declarations for the STL stream I/O operations to add asynchronous functionality of the `thread_control` class. It also contains the necessary declarations of extensions for the standard C++ STL streams I/O operations: output operator >> and input operator <<.

You can call synchronization method `wait()` to wait for completion of any I/O operations with the file object. If the `wait()` method is not called explicitly, it is called implicitly in the object destructor.

Public Interface of Template Class async_class

The following methods define the public interface of the template class `async_class`:

- `get_last_operation_id()`
- `wait()`
- `get_status()`
- `get_last_error()`
- `get_error_operation_id()`
- `stop_queue()`
- `resume_queue()`
- `clear_queue()`

Library Restrictions

Intel's C++ asynchronous I/O template class does not control the integrity or validity of the objects during asynchronous operation. Such control should be done by the user.

For application stability in the Visual Studio 2003 environment, link the C++ part of `libacaio.lib` library with multi-threaded `msvcrt` run-time library. Use `/MT` or `/MTd` compiler option.

See Also

Example of Using async_class Template Class

get_last_operation_id

Returns ID of the last added operation.

Syntax

```
void get_last_operation_id(void)
```

Description

This method returns the ID of the last added operation. Use this ID to get the status of operation or to wait for the operation to complete.

Return Values

Nothing

wait

Stops execution of current thread.

Syntax

```
int wait(void)
```

```
int wait(unsigned int operation_id)
```

Description

Method `wait(void)` stops execution of the current thread until all the asynchronous operations are completed.

Method `wait(operation_id)` stops execution of the current thread until the operation identified by *operation_id* is completed.

Return Values

-1 : On error during queue execution

Call the `get_last_error()` method to check the error code.

get_status

Returns status of specified operation.

Syntax

```
void get_status(unsigned int operation_id)
```

Description

This method returns the status of an operation, specified by *operation_id,* without stopping current thread execution.

Return Values

STATUS_WAIT: Operation is waiting for execution.

STATUS_COMPLETED: Operation finished execution.

STATUS_ERROR: An error occurred during operation execution.

STATUS_EXECUTE: Operation is executing.

STATUS_BLOCKED: Execution of the queue was blocked after some earlier errors.

get_last_error

Returns the error code of the last failed operation.

Syntax

```
unsigned int get_last_error()
```

Description

This method returns the error code of the last failed operation. If the error occurs during the execution of an asynchronous operation, the asynchronous thread stops executing the queue of asynchronous operations and waits for new user requests.

To obtain the error status, use the `wait()` and `get_status()` methods.

Return Values

Error code of last failed operation.

This error code is equal to the value returned by `GetLastError()` function on the Windows* platform. If the error occurs during the execution of an asynchronous operation, the asynchronous thread stops executing the queue of asynchronous operations and waits for new user requests.

get_error_operation_id

Returns the ID of the last failed operation.

Syntax

```
unsigned int get_error_operation_id()
```

Description

This method returns the ID of the last failed operation. If the error occurs during the execution of an asynchronous operation, the asynchronous thread stops executing the queue of the asynchronous operations and waits for new user requests.

To obtain the error status of the failed operation, use the `wait()` and `get_status()` methods.

Return Values

ID of last failed operation.

stop_queue

Stops queue execution.

Syntax

```
int stop_queue()
```

Description

This method allows you to control the asynchronous operations queue by stopping queue execution.

Return Values

0: On success

-1: On error

resume_queue

Resumes queue execution.

Syntax

```
int resume_queue()
```

Description

This method allows you to control the asynchronous operations queue by resuming queue execution.

Return Values

0: On success

-1: On error

clear_queue

Clears stopped or error-interrupted queues.

Syntax

```
void push_back_operation(class base_operation*)
```

Description

This method clears the content of stopped queues or queues interrupted by errors.

Return Values

0: On success

-1: On error

Example for Using async_class Template Class

The following example illustrates how Intel's C++ asynchronous I/O template class can be used. Consider the following code that writes arrays of floats to an external file.

```
// Data is array of floats
std::vector<float>  v(10000);

// User defines new operator << for std::vector<float> type
std::ofstream& operator << (std::ofstream & str, std::vector<float> & vec)
{
// User's output actions
...
 }
...
// Output file declaration - object of standard ofstream STL class
std::ofstream external_file("output.txt");
...
// Output operations
external_file << v;
```

The following code illustrates the changes to be made to the above code to execute the output operation asynchronously.

```
// Add new header to support STL asynchronous IO operations

#include <aiostream.h>
...

std::vector<float>  v(10000);

std::ofstream& operator << (std::ofstream & str, std::vector<float> & vec)
{... }
...
// Declare output file as the instance of new async::async_class template
// class.
// New inherited from STL ofstream type is declared
async::async_class<std::ofstream> external_file("output.txt");
...
external_file << v;
...
// Add stop operation, to wait the completion of all asynchronous IO //operations
external_file.wait();
…
```

Performance Recommendations

It is recommended not to use asynchronous mode for small objects. For example, do not use asynchronous mode when the output standard type value in a loop where execution of other loop operations takes less time than output of the same value to the STL stream.

However, if you can find the balance between output of small data and its previous calculation inside the loop, you still have some stable performance improvement.

For example, in the following code, the program reads two matrices from external files, calculates the elements of a third matrix, and prints out the elements inside the loop.

```
#define ARR_LEN 900
{
  std::ifstream fA("A.txt");
  fA >> A;
  std::ifstream fB("B.txt");
```

```
  fB >> B;
  std::ofstream fC(f);

  for(int i=0; i< ARR_LEN; i++)
   {
    for(int j=0; j< ARR_LEN; j++)
    {
     C[i][j] = 0;
     for(int k=0; k < ARR_LEN; k++)
     C[i][j]+ = A[i][k]*B[k][j]*sin((float)(k))*cos((float)(-k))*sin((float)(k+1)
     )*cos((float)(-k-1));
     fC << C[i][j] << std::endl;
    }
   }
}
```

By increasing matrix size, you can also achieve performance improvement during parallel data reading from two files.

IEEE 754-2008 Binary Floating-Point Conformance Library

The Intel® IEEE 754-2008 Binary Floating-Point Conformance Library provides all operations mandated by the IEEE 754-2008 standard for binary32 and binary64 binary floating-point interchange formats.

Many routines in the *libbfp754* Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Intel® IEEE 754-2008 Binary Floating-Point Conformance Library and Usage

The Intel® IEEE 754-2008 Binary Floating-Point Conformance Library provides all operations mandated by the IEEE 754-2008 standard for binary32 and binary64 binary floating-point interchange formats. The minimum requirements for correct operation of the library are an Intel® Pentium® 4 processor and an operating system supporting Intel® Streaming SIMD Extensions 2 (Intel® SSE2) instructions.

The library supports all four rounding-direction attributes mandated by the IEEE 754-2008 standard for binary floating-point arithmetic: `roundTiesToEven`, `roundTowardPositive`, `roundTowardNegative`, `roundTowardZero`. The additional rounding-direction attribute, `roundTiesToAway`, is not required by the standard, hence, not fully supported in this library. The default rounding-direction attribute is set as `roundTiesToEven`.

The library also supports all mandated exceptions (invalid operation, division by zero, overflow, underflow, and inexact) and sets flags accordingly under default exception handling. Alternate exception handling, which is optional in the standard, is not supported.

The `bfp754.h` header file includes prototypes for the library functions. For a complete list of the functions available, refer to the Function List. The user also needs to specify linker option `-lbfp754` and floating-point semantics control option `-fp-model strict` in order to use the library.

Many routines in the *libbfp754* Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Operations

The IEEE standard 754-2008 defines four types of operations.

1. General-computational operations that produce correctly rounded floating-point or integer results. These operations might signal the floating-point exceptions.
2. Quiet-computational operations that produce floating-point results. These operations do not signal any floating-point exceptions.
3. Signaling-computational operations that produce no floating-point results. These operations might signal floating-point exceptions.
4. Non-computational operations that produce no floating-point results. These operations do not signal floating-point exceptions.

	Produce result	**Produce no result**
Might signal FP exception	General-computational	Signaling-computational
Do not signal FP exception	Quiet-computational	Non-computational

The standard also distinguishes among operations by their floating-point operand formats and result format for general-computational operations:

1. Homogenous general-computational operations whose floating-point operands and floating-point result are in the same format.
2. *formatOf* general-computational operations whose floating-point operands and floating-point result have different formats.

NOTE
The IEEE 754-2008 standard requires that all *formatOf* general-computational operations be computed without any loss of precision before converting to the destination format. This may differ from how these operations are implemented on most hardware and software.

For example, when all operands are in binary64 format and the destination format is binary32, most hardware and software implementations would first compute an intermediate result rounded in binary64 and then convert the intermediate result to binary32. This double rounding procedure may produce a result different from what is defined in the standard under certain rounding mode. For example: `x = 0x3ff0000010000000 = 1.000000000000000000000001_2`, `y = 0x3ca0000000000000 = 1.0_2*2^(-53) x+y = 1.00000000000000000000000100000000000000000000000000001_2`

When the rounding-direction attribute is set to `roundTiesToEven`, using double rounding procedure, the addition result rounds to `1.000000000000000000000001_2 (0x3ff0000010000000)` in binary64, which would then round to `1 (0x3f800000)` in binary32. On the other hand, according to the standard, the addition result should round to `1.00000000000000000000001_2 (0x3f800001)` in binary32.

Data Types

The following table correlates the names of the formats used in defining operations in the standard with their C99 types used in this library.

Format Name	**Definition**	**C99 Type**
`binary32`	IEEE 754-2008 binary32 interchange format	`float`

Format Name	Definition	C99 Type
`binary64`	IEEE 754-2008 binary64 interchange format	`double`
`int`	Integer operand formats	`int, unsigned int, long long int, unsigned long long int`
`int32`	Signed 32-bit integer	`int`
`uint32`	Unsigned 32-bit integer	`unsigned int`
`int64`	Signed 64-bit integer	`long long int`
`uint64`	Unsigned 64-bit integer	`unsigned long long int`
`boolean`	Boolean value represented by generic integer type	`int`
`enum`	Enumerated values of floating-point class	`int`
	Enumerated values of floating-point radix	`int`
`logBFormat`	Type for the destination of the `logB` operation and the scale exponent operand of the `scaleB` operation	`int`
`decimalCharacterSequence`	Decimal character sequence	`char*`
`hexCharacterSequence`	Hexadecimal-significand character sequence	
`exceptionGroup`	Set of exceptions as a set of booleans	`int`
`flags`	Set of status flags	`int`
`binaryRoundingDirection`	Rounding direction for binary	`int`
`modeGroup`	Dynamically-specifiable modes	`int`
`void`	No explicit operand or result	`void`

Use the Intel® IEEE 754-2008 Binary Floating-Point Conformance Library

Many routines in the *libbfp754* Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

To use the library, include the header file, `bfp754.h`, in your program.

Here is an example program illustrating the use of the library on Linux* OS.

```
//binary.c
#include <stdio.h>
#include <bfp754.h>
```

```
int main(){
  double a64, b64;
  float c32;
  a64 = 1.000000059604644775390625;
  b64 = 1.1102230246251565404236316680908203125e-16;
  c32 = __binary32_add_binary64_binary64(a64, b64);
  printf("The addition result using the libary: %8.8f\n", c32);
  c32 = a64 + b64;
  printf("The addition result without the libary: %8.8f\n", c32);
  return 0;
}
```

To compile `binary.c`, use the command:

```
icc -fp-model source -fp-model except binary.c -lbfp754
```

The output of `a.out` will look similar to the following:

```
The addition result using the libary: 1.00000012
The addition result without the libary: 1.00000000
```

Homogeneous General-Computational Operations Functions

Many routines in the *libbfp754* Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The Intel® IEEE 754-2008 Binary Conformance Library supports the following functions for homogeneous general-computational operations:

round_integral_nearest_even

Description: The function rounds floating-point number `x` to its nearest integral value, with the halfway (tied) case rounding to even.

Calling interface:

```
float __binary32_round_integral_nearest_even(float x);
double __binary64_round_integral_nearest_even(double x);
```

round_integral_nearest_away

Description: The function rounds floating-point number `x` to its nearest integral value, with the halfway (tied) case rounding away from zero.

Calling interface:

```
float __binary32_round_integral_nearest_away(float x);
double __binary64_round_integral_nearest_away(double x);
```

round_integral_zero

Description: The function rounds floating-point number `x` to the closest integral value toward zero.

Calling interface:

```
float __binary32_round_integral_zero(float x);
double __binary64_round_integral_zero(double x);
```

round_integral_positive

Description: The function rounds floating-point number `x` to the closest integral value toward positive infinity.

Calling interface:

```
float __binary32_round_integral_positive(float x);
double __binary64_round_integral_positive(double x);
```

round_integral_negative

Description: The function rounds floating-point number `x` to the closest integral value toward negative infinity.

Calling interface:

```
float __binary32_round_integral_negative(float x);
double __binary64_round_integral_negative(double x);
```

round_integral_exact

Description: The function rounds floating-point number `x` to the closest integral value according to the rounding-direction applicable.

Calling interface:

```
float __binary32_round_integral_exact(float x);
double __binary64_round_integral_exact(double x);
```

next_up

Description: The function returns the least floating-point number in the same format as `x` that is greater than `x`.

Calling interface:

```
float __binary32_next_up(float x);
```

```
double __binary64_next_up(double x);
```

next_down

Description: The function returns the largest floating-point number in the same format as `x` that is less than `x`.

Calling interface:

```
float __binary32_next_down(float x);
double __binary64_next_down(double x);
```

rem

Description: The function returns the remainder of `x` and `y`.

Calling interface:

```
float __binary32_rem(float x, float y);
double __binary64_rem(double x, double y);
```

minnum

Description: The function returns the minimal value of `x` and `y`.

Calling interface:

```
float __binary32_minnum(float x, float y);
double __binary64_minnum(double x, double y);
```

maxnum

Description: The function returns the maximal value of `x` and `y`.

Calling interface:

```
float __binary32_maxnum(float x, float y);
double __binary64_maxnum(double x, double y);
```

minnum_mag

Description: The function returns the minimal absolute value of `x` and `y`.

Calling interface:

```
float __binary32_minnum_mag(float x, float y);
double __binary64_minnum_mag(double x, double y);
```

maxnum_mag

Description: The function returns the maximal absolute value of `x` and `y`.

Calling interface:

```
float __binary32_maxnum_mag(float x, float y);
double __binary64_maxnum_mag(double x, double y);
```

scalbn

Description: The function computes x X 2^n for integer value `n`.

Calling interface:

```
float __binary32_scalbn(float x, int n);
double __binary64_scalbn(double x, int n);
```

ilogb

Description: The function returns the exponent part of `x` as integer.

Calling interface:

```
int __binary32_ilogb(float x);
int __binary64_ilogb(double x);
```

formatOf General-Computational Operations Functions

Many routines in the *libbfp754* Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The Intel® IEEE 754-2008 Binary Conformance Library supports the following functions for *formatOf* general-computational operations:

add

Description: The function computes the addition of two floating-point numbers; the result is then converted to the destination format.

Calling interface:

```
float __binary32_add_binary32_binary32(float x, float y);
float __binary32_add_binary32_binary64(float x, double y);
float __binary32_add_binary64_binary32(double x, float y);
float __binary32_add_binary64_binary64(double x, double y);
double __binary64_add_binary32_binary32(float x, float y);
double __binary64_add_binary32_binary64(float x, double y);
double __binary64_add_binary64_binary32(double x, float y);
double __binary64_add_binary64_binary64(double x, double y);
```

sub

Description: The function computes the subtraction of two floating-point numbers; the result is then converted to the destination format.

Calling interface:

```
float __binary32_sub_binary32_binary32(float x, float y);
float __binary32_sub_binary32_binary64(float x, double y);
float __binary32_sub_binary64_binary32(double x, float y);
float __binary32_sub_binary64_binary64(double x, double y);
double __binary64_sub_binary32_binary32(float x, float y);
double __binary64_sub_binary32_binary64(float x, double y);
double __binary64_sub_binary64_binary32(double x, float y);
double __binary64_sub_binary64_binary64(double x, double y);
```

mul

Description: The function computes the multiplication of two floating-point numbers; the result is then converted to the destination format.

Calling interface:

```
float __binary32_mul_binary32_binary32(float x, float y);
float __binary32_mul_binary32_binary64(float x, double y);
float __binary32_mul_binary64_binary32(double x, float y);
float __binary32_mul_binary64_binary64(double x, double y);
double __binary64_mul_binary32_binary32(float x, float y);
```

```
double __binary64_mul_binary32_binary64(float x, double y);
double __binary64_mul_binary64_binary32(double x, float y);
double __binary64_mul_binary64_binary64(double x, double y);
```

div

Description: The function computes the division of two floating-point numbers; the result is then converted to the destination format.

Calling interface:

```
float __binary32_div_binary32_binary32(float x, float y);
float __binary32_div_binary32_binary64(float x, double y);
float __binary32_div_binary64_binary32(double x, float y);
float __binary32_div_binary64_binary64(double x, double y);
double __binary64_div_binary32_binary32(float x, float y);
double __binary64_div_binary32_binary64(float x, double y);
double __binary64_div_binary64_binary32(double x, float y);
double __binary64_div_binary64_binary64(double x, double y);
```

sqrt

Description: The function computes the square root of floating-point number; the result is then converted to the destination format.

Calling interface:

```
float __binary32_sqrt_binary32(float x);
float __binary32_sqrt_binary64(double x);
double __binary32_sqrt_binary32(float x);
double __binary32_sqrt_binary64(double x);
```

fma

Description: The function computes the fused multiply and add of three floating-point numbers *x*, *y*, and *z* as (*x*×*y*) +*z*; the result is then converted to the destination format.

Calling interface:

```
float __binary32_fma_binary32_binary32_binary32(float x, float y, float z);
float __binary32_fma_binary32_binary32_binary64(float x, float y, double z);
float __binary32_fma_binary32_binary64_binary32(float x, double y, float z);
float __binary32_fma_binary32_binary64_binary64(float x, double y, double z);
float __binary32_fma_binary64_binary32_binary32(double x, float y, float z);
float __binary32_fma_binary64_binary32_binary64(double x, float y, double z);
float __binary32_fma_binary64_binary64_binary32(double x, double y, float z);
float __binary32_fma_binary64_binary64_binary64(double x, double y, double z);
double __binary64_fma_binary32_binary32_binary32(float x, float y, float z);
double __binary64_fma_binary32_binary32_binary64(float x, float y, double z);
double __binary64_fma_binary32_binary64_binary32(float x, double y, float z);
double __binary64_fma_binary32_binary64_binary64(float x, double y, double z);
double __binary64_fma_binary64_binary32_binary32(double x, float y, float z);
double __binary64_fma_binary64_binary32_binary64(double x, float y, double z);
double __binary64_fma_binary64_binary64_binary32(double x, double y, float z);
double __binary64_fma_binary64_binary64_binary64(double x, double y, double z);
```

from_int32 / from_uint32 / from_int64 / from_uint64

Description: This function converts integral values in the specified integer format to floating-point number.

Calling interface:

```
float __binary32_from_int32(int n);
double __binary64_from_int32(int n);
float __binary32_from_uint32(unsigned int n);
double __binary64_from_uint32(unsigned int n);
float __binary32_from_int64(long long int n);
double __binary64_from_int64(long long int n);
float __binary32_from_uint64(unsigned long long int n);
double __binary64_from_uint64(unsigned long long int n);
```

to_int32_rnint / to_uint32_rnint / to_int64_rnint / to_uint64_rnint

Description: This function rounds floating-point number to the nearest integral value in the specified integer format, with halfway cases rounded to even, without signaling the inexact exception.

Calling interface:

```
int __binary32_to_int32_rnint(float x);
int __binary64_to_int32_rnint(double x);
unsigned int __binary32_to_uint32_rnint(float x);
unsigned int __binary64_to_uint32_rnint(double x);
long long int __binary32_to_int64_rnint(float x);
long long int __binary64_to_int64_rnint(double x);
unsigned long long int __binary32_to_uint64_rnint(float x);
unsigned long long int __binary64_to_uint64_rnint(double x);
```

to_int32_int / to_uint32_int / to_int64_int / to_uint64_int

Description: This function rounds floating-point number to the nearest integral value in the specified integer format toward zero, without signaling the inexact exception.

Calling interface:

```
int __binary32_to_int32_int(float x);
int __binary64_to_int32_int(double x);
unsigned int __binary32_to_uint32_int(float x);
unsigned int __binary64_to_uint32_int(double x);
long long int __binary32_to_int64_int(float x);
long long int __binary64_to_int64_int(double x);
unsigned long long int __binary32_to_uint64_int(float x);
unsigned long long int __binary64_to_uint64_int(double x);
```

to_int32_ceil/ to_uint32_ceil / to_int64_ceil / to_uint64_ceil

Description: This function rounds floating-point number to the nearest integral value in the specified integer format toward positive infinity, without signaling the inexact exception.

Calling interface:

```
int __binary32_to_int32_ceil(float x);
int __binary64_to_int32_ceil(double x);
unsigned int __binary32_to_uint32_ceil(float x);
unsigned int __binary64_to_uint32_ceil(double x);
long long int __binary32_to_int64_ceil(float x);
long long int __binary64_to_int64_ceil(double x);
```

```
unsigned long long int __binary32_to_uint64_ceil(float x);
unsigned long long int __binary64_to_uint64_ceil(double x);
```

to_int32_floor/ to_uint32_floor / to_int64_floor / to_uint64_floor

Description: This function rounds floating-point number to the nearest integral value in the specified integer format toward negative infinity, without signaling the inexact exception.

Calling interface:

```
int __binary32_to_int32_floor(float x);
int __binary64_to_int32_floor(double x);
unsigned int __binary32_to_uint32_floor(float x);
unsigned int __binary64_to_uint32_floor(double x);
long long int __binary32_to_int64_floor(float x);
long long int __binary64_to_int64_floor(double x);
unsigned long long int __binary32_to_uint64_floor(float x);
unsigned long long int __binary64_to_uint64_floor(double x);
```

to_int32_rninta / to_uint32_rninta / to_int64_rninta / to_uint64_rninta

Description: This function rounds floating-point number to the nearest integral value in the specified integer format, with halfway cases rounded away from zero, without signaling the inexact exception.

Calling interface:

```
int __binary32_to_int32_rninta(float x);
int __binary64_to_int32_rninta(double x);
unsigned int __binary32_to_uint32_rninta(float x);
unsigned int __binary64_to_uint32_rninta(double x);
long long int __binary32_to_int64_rninta(float x);
long long int __binary64_to_int64_rninta(double x);
unsigned long long int __binary32_to_uint64_rninta(float x);
unsigned long long int __binary64_to_uint64_rninta(double x);
```

to_int32_xrnint / to_uint32_xrnint / to_int64_xrnint / to_uint64_xrnint

Description: This function rounds floating-point number to the nearest integral value in the specified integer format, with halfway cases rounded to even, signaling if inexact.

Calling interface:

```
int __binary32_to_int32_xrnint(float x);
int __binary64_to_int32_xrnint(double x);
unsigned int __binary32_to_uint32_xrnint(float x);
unsigned int __binary64_to_uint32_xrnint(double x);
long long int __binary32_to_int64_xrnint(float x);
long long int __binary64_to_int64_xrnint(double x);
unsigned long long int __binary32_to_uint64_xrnint(float x);
unsigned long long int __binary64_to_uint64_xrnint(double x);
```

to_int32_xint / to_uint32_xint / to_int64_xint / to_uint64_xint

Description: This function rounds floating-point number to the nearest integral value in the specified integer format toward zero, signaling if inexact.

Calling interface:

```
int __binary32_to_int32_xint(float x);
```

```
int __binary64_to_int32_xint(double x);
unsigned int __binary32_to_uint32_xint(float x);
unsigned int __binary64_to_uint32_xint(double x);
long long int __binary32_to_int64_xint(float x);
long long int __binary64_to_int64_xint(double x);
unsigned long long int __binary32_to_uint64_xint(float x);
unsigned long long int __binary64_to_uint64_xint(double x);
```

to_int32_xceil / to_uint32_xceil / to_int64_xceil / to_uint64_xceil

Description: This function rounds floating-point number to the nearest integral value in the specified integer format toward positive infinity, signaling if inexact.

Calling interface:

```
int __binary32_to_int32_xceil(float x);
int __binary64_to_int32_xceil(double x);
unsigned int __binary32_to_uint32_xceil(float x);
unsigned int __binary64_to_uint32_xceil(double x);
long long int __binary32_to_int64_xceil(float x);
long long int __binary64_to_int64_xceil(double x);
unsigned long long int __binary32_to_uint64_xceil(float x);
unsigned long long int __binary64_to_uint64_xceil(double x);
```

to_int32_xfloor / to_uint32_xfloor / to_int64_xfloor / to_uint64_xfloor

Description: This function rounds floating-point number to the nearest integral value in the specified integer format toward negative infinity, signaling if inexact.

Calling interface:

```
int __binary32_to_int32_xfloor(float x);
int __binary64_to_int32_xfloor(double x);
unsigned int __binary32_to_uint32_xfloor(float x);
unsigned int __binary64_to_uint32_xfloor(double x);
long long int __binary32_to_int64_xfloor(float x);
long long int __binary64_to_int64_xfloor(double x);
unsigned long long int __binary32_to_uint64_xfloor(float x);
unsigned long long int __binary64_to_uint64_xfloor(double x);
```

to_int32_xrninta / to_uint32_xrninta / to_int64_xrninta / to_uint64_xrninta

Description: This function rounds floating-point number to the nearest integral value in the specified integer format, with halfway cases rounded away from zero, signaling if inexact.

Calling interface:

```
int __binary32_to_int32_xrninta(float x);
int __binary64_to_int32_xrninta(double x);
unsigned int __binary32_to_uint32_xrninta(float x);
unsigned int __binary64_to_uint32_xrninta(double x);
long long int __binary32_to_int64_xrninta(float x);
long long int __binary64_to_int64_xrninta(double x);
unsigned long long int __binary32_to_uint64_xrninta(float x);
unsigned long long int __binary64_to_uint64_xrninta(double x);
```

binary32_to_binary64

Description: This function converts floating-point number in binary32 format to binary64 format.

Calling interface:

```
double __binary32_to_binary64(float x);
```

binary64_to_binary32

Description: This function rounds floating-point number in binary64 format to binary32 format.

Calling interface:

```
float __binary64_to_binary32(double x);
```

from_string

Description: This function converts decimal character sequence to floating-point number.

Calling interface:

```
float __binary32_from_string(char * s);
double __binary64_from_string(char * s);
```

to_string

Description: This function converts floating-point number to decimal character sequence.

Calling interface:

```
char *__binary32_to_string(float x);
char *__binary64_to_string(double x);
```

from_hexstring

Description: This function converts hexadecimal character sequence to floating-point number.

Calling interface:

```
float __binary32_from_hexstring(char * s);
double __binary64_from_hexstring(char * s);
```

to_hexstring

Description: This function converts floating-point number to hexadecimal character sequence.

Calling interface:

```
char *__binary32_to_hexstring(float x);
char *__binary64_to_hexstring(double x);
```

Quiet-Computational Operations Functions

Many routines in the *libbfp754* Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The Intel® IEEE 754-2008 Binary Conformance Library supports the following functions for quiet-computational operations:

copy

Description: The function copies input floating-point number `x` to output in the same floating-point format, without any change to the sign.

Calling interface:

```
float __binary32_copy(float x);
double __binary64_copy(double x);
```

NOTE
When the input is a signaling NaN, two different outcomes are allowed by the standard. The operation could either signal invalid exception with quieted signaling NaN as output, or deliver signaling NaN as output without signaling any exception.

negate

Description: The function copies input floating-point number x to output in the same floating-point format, reversing the sign.

Calling interface:
```
float __binary32_negate(float x);
double __binary64_negate(double x);
```

NOTE
When the input is a signaling NaN, two different outcomes are allowed by the standard. The operation could either signal invalid exception with quieted signaling NaN as output, or deliver signaling NaN as output without signaling any exception.

abs

Description: The function copies input floating-point number x to output in the same floating-point format, setting the sign to positive.

Calling interface:
```
float __binary32_abs(float x);
double __binary64_abs(double x);
```

NOTE
When the input is a signaling NaN, two different outcomes are allowed by the standard. The operation could either signal invalid exception with quieted signaling NaN as output, or deliver signaling NaN as output without signaling any exception.

copysign

Description: The function copies input floating-point number x to output in the same floating-point format, with the same sign as y.

Calling interface:
```
float __binary32_copysign(float x, float y);
double __binary64_copysign(double x, double y);
```

NOTE
When the first input is a signaling NaN, two different outcomes are allowed by the standard. The operation could either signal invalid exception with quieted signaling NaN as output, or deliver signaling NaN as output without signaling any exception.

Signaling-Computational Operations Functions

Many routines in the *libbfp754* Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The Intel® IEEE 754-2008 Binary Conformance Library supports the following functions for signaling-computational operations:

quiet_equal

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is equal, returns 0 (false) otherwise. The function signals invalid operation exception when signaling `NaN` is in the inputs.

Calling interface:

```
int __binary32_quiet_equal_binary32 (float x, float y);
int __binary32_quiet_equal_binary64(float x, double y);
int __binary64_quiet_equal_binary32(double x, float y);
int __binary64_quiet_equal_ binary64(double x, double y);
```

quiet_not_equal

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is not equal, returns 0 (false) otherwise. The function signals invalid operation exception when signaling `NaN` is one of the inputs.

Calling interface:

```
int __binary32_quiet_not_equal_binary32(float x, float y);
int __binary32_quiet_not_equal_binary64(float x, double y);
int __binary64_quiet_not_equal_binary32(double x, float y);
int __binary64_quiet_not_equal_binary64(double x, double y);
```

signaling_equal

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is equal, returns 0 (false) otherwise. The function signals invalid operation exception when `NaN` is in the inputs.

Calling interface:

```
int __binary32_signaling_equal_binary32(float x, float y);
int __binary32_signaling_equal_binary64(float x, double y);
int __binary64_signaling_equal_binary32(double x, float y);
int __binary64_signaling_equal_binary64(double x, double y);
```

signaling_greater

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is greater, returns 0 (false) otherwise. The function signals invalid operation exception when `NaN` is in the inputs.

Calling interface:

```
int __binary32_signaling_greater_binary32(float x, float y);
int __binary32_signaling_greater_binary64(float x, double y);
int __binary64_signaling_greater_binary32(double x, float y);
int __binary64_signaling_greater_binary64(double x, double y);
```

signaling_greater_equal

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is greater or equal, returns 0 (false) otherwise. The function signals invalid operation exception when `NaN` is in the inputs.

Calling interface:

```
int __binary32_signaling_greater_equal_binary32(float x, float y);
int __binary32_signaling_greater_equal_binary64(float x, double y);
int __binary64_signaling_greater_equal_binary32(double x, float y);
int __binary64_signaling_greater_equal_binary64(double x, double y);
```

signaling_less

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is less, returns 0 (false) otherwise. The function signals invalid operation exception when `NaN` is in the inputs.

Calling interface:

```
int __binary32_signaling_less_binary32(float x, float y);
int __binary32_signaling_less_binary64(float x, double y);
int __binary64_signaling_less_binary32(double x, float y);
int __binary64_signaling_less_binary64(double x, double y);
```

signaling_less_equal

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is less or equal, returns 0 (false) otherwise. The function signals invalid operation exception when `NaN` is in the inputs.

Calling interface:

```
int __binary32_signaling_less_equal_binary32(float x, float y);
int __binary32_signaling_less_equal_binary64(float x, double y);
int __binary64_signaling_less_equal_binary32(double x, float y);
int __binary64_signaling_less_equal_binary64(double x, double y);
```

signaling_not_equal

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is not equal, returns 0 (false) otherwise. The function signals invalid operation exception when `NaN` is in the inputs.

Calling interface:

```
int __binary32_signaling_not_equal_binary32(float x, float y);
int __binary32_signaling_not_equal_binary64(float x, double y);
int __binary64_signaling_not_equal_binary32(double x, float y);
int __binary64_signaling_not_equal_binary64(double x, double y);
```

signaling_not_greater

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is not greater, returns 0 (false) otherwise. The function signals invalid operation exception when `NaN` is in the inputs.

Calling interface:

```
int __binary32_signaling_not_greater_binary32(float x, float y);
int __binary32_signaling_not_greater_binary64(float x, double y);
int __binary64_signaling_not_greater_binary32(double x, float y);
int __binary64_signaling_not_greater_binary64(double x, double y);
```

signaling_less_unordered

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is less or unordered, returns 0 (false) otherwise. The function signals invalid operation exception when `NaN` is in the inputs.

Calling interface:

```
int __binary32_signaling_less_unordered_binary32(float x, float y);
int __binary32_signaling_less_unordered_binary64(float x, double y);
int __binary64_signaling_less_unordered_binary32(double x, float y);
int __binary64_signaling_less_unordered_binary64(double x, double y);
```

signaling_not_less

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is not less, returns 0 (false) otherwise. The function signals invalid operation exception when `NaN` is in the inputs.

Calling interface:

```
int __binary32_signaling_not_less_ binary32(float x, float y);
int __binary32_signaling_not_less_binary64(float x, double y);
int __binary64_signaling_not_less_binary32(double x, float y);
int __binary64_signaling_not_less_binary64 (double x, double y);
```

signaling_greater_unordered

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is greater or unordered, returns 0 (false) otherwise. The function signals invalid operation exception when `NaN` is in the inputs.

Calling interface:

```
int __binary32_signaling_greater_unordered_binary32(float x, float y);
int __binary32_signaling_greater_unordered_binary64(float x, double y);
int __binary64_ signaling_greater_unordered_binary32(double x, float y);
int __binary64_signaling_greater_unordered_binary64(double x, double y);
```

quiet_greater

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is greater, returns 0 (false) otherwise. The function signals invalid operation exception when signaling `NaN` is one of the inputs.

Calling interface:

```
int __binary32_quiet_greater_binary32(float x, float y);
int __binary32_quiet_greater_binary64(float x, double y);
int __binary64_quiet_greater_binary32(double x, float y);
int __binary64_quiet_greater_binary64(double x, double y);
```

quiet_greater_equal

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is greater or equal, returns 0 (false) otherwise. The function signals invalid operation exception when signaling `NaN` is one of the inputs.

Calling interface:

```
int __binary32_quiet_greater_equal_binary32(float x, float y);
int __binary32_quiet_greater_equal_binary64(float x, double y);
int __binary64_quiet_greater_equal_binary32(double x, float y);
int __binary64_quiet_greater_equal_binary64(double x, double y);
```

quiet_less

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is less, returns 0 (false) otherwise. The function signals invalid operation exception when signaling `NaN` is one of the inputs.

Calling interface:

```
int __binary32_quiet_less_binary32(float x, float y);
int __binary32_quiet_less_binary64(float x, double y);
int __binary64_quiet_less_binary32(double x, float y);
int __binary64_quiet_less_binary64(double x, double y);
```

quiet_less_equal

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is less or equal, returns 0 (false) otherwise. The function signals invalid operation exception when signaling `NaN` is one of the inputs.

Calling interface:

```
int __binary32_quiet_less_equal_binary32(float x, float y);
int __binary32_quiet_less_equal_binary64(float x, double y)
int __binary64_quiet_less_equal_binary32(double x, float y);
int __binary64_quiet_less_equal_binary64(double x, double y);
```

quiet_unordered

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is unordered, returns zero (false) otherwise. The function signals invalid operation exception when signaling `NaN` is one of the inputs

Calling interface:

```
int __binary32_quiet_unordered_binary32(float x, float y);
int __binary32_quiet_unordered_binary64(float x, double y);
int __binary64_quiet_unordered_binary32(double x, float y);
int __binary64_quiet_unordered_binary64(double x, double y);
```

quiet_not_greater

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is not greater, returns zero (false) otherwise. The function signals invalid operation exception when signaling `NaN` is one of the inputs.

Calling interface:

```
int __binary32_quiet_not_greater_binary32(float x, float y);
int __binary32_quiet_not_greater_binary64(float x, double y);
int __binary64_quiet_not_greater_binary32(double x, float y);
int __binary64_quiet_not_greater_binary64(double x, double y);
```

quiet_less_unordered

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is less or unordered, returns 0 (false) otherwise. The function signals invalid operation exception when signaling `NaN` is one of the inputs.

Calling interface:

```
int __binary32_quiet_less_unordered_binary32(float x, float y);
int __binary32_quiet_less_unordered_binary64(float x, double y);
int __binary64_quiet_less_unordered_binary32(double x, float y);
int __binary64_quiet_less_unordered_binary64(double x, double y);
```

quiet_not_less

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is not less, returns zero (false) otherwise. The function signals invalid operation exception when signaling `NaN` is one of the inputs.

Calling interface:

```
int __binary32_quiet_not_less_binary32(float x, float y);
int __binary32_quiet_not_less_binary64(float x, double y);
int __binary64_quiet_not_less_binary32(double x, float y);
int __binary64_quiet_not_less_binary64(double x, double y);
```

quiet_greater_unordered

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is greater or unordered, returns 0 (false) otherwise. The function signals invalid operation exception when signaling `NaN` is one of the inputs.

Calling interface:

```
int __binary32_quiet_greater_unordered_binary32(float x, float y);
int __binary32_quiet_greater_unordered_binary64(float x, double y);
int __binary64_quiet_greater_unordered_binary32(double x, float y);
int __binary64_quiet_greater_unordered_binary64(double x, double y);
```

quiet_ordered

Description: The function returns 1 (true) if the relation between the two inputs `x` and `y` is ordered, returns 0 (false) otherwise. The function signals invalid operation exception when signaling `NaN` is one of the inputs.

Calling interface:

```
int __binary32_quiet_ordered_binary32(float x, float y);
int __binary32_quiet_ordered_binary64(float x, double y);
int __binary64_quiet_ordered_binary32(double x, float y);
int __binary64_quiet_ordered_binary64(double x, double y);
```

Non-Computational Operations Functions

Many routines in the *libbfp754* Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The Intel® IEEE 754-2008 Binary Conformance Library supports the following functions for non-computational operations:

is754version1985

Description: The function returns 1, if and only if this programming environment conforms to IEEE Std. 754-1985, otherwise returns 0.

Calling interface:

```
int __binary_is754version1985(void);
```

> **NOTE**
> This function in this library always returns 0.

is754version2008

Description: The function returns 1, if and only if this programming environment conforms to IEEE Std. 754-2008, otherwise returns 0.

Calling interface:

```
int __binary_is754version2008(void);
```

> **NOTE**
> This function in this library always returns 1.

class

Description: The function returns which class of the ten classes (`signalingNaN`, `quietNaN`, `negativeInfinity`, `negativeNormal`, `negativeSubnormal`, `negativeZero`, `positiveZero`, `positiveSubnormal`, `positiveNormal`, `positiveInfinity`) the input floating-point number `x` belongs.

Return value	Class
0	signalingNaN
1	quietNaN
2	negativeInfinity
3	negativeNormal
4	negativeSubnormal
5	negativeZero
6	positiveZero
7	positiveSubnormal
8	positiveNormal
9	positiveInfinity

Calling interface:

```
int __binary32_class(float x);
int __binary64_class(double x);
```

isSignMinus

Description: The function returns 1, if and only if its argument has negative sign.

Calling interface:

```
int __binary32_isSignMinus(float x);
int __binary64_isSignMinus(double x);
```

isNormal

Description: The function returns 1, if and only if its argument is normal (not `zero`, `subnormal`, `infinite`, or `NaN`).

Calling interface:

```
int __binary32_isNormal(float x);
```

```
int __binary64_isNormal(double x);
```

isFinite

Description: The function returns 1, if and only if its argument is `finite` (not `infinite` or `NaN`).

Calling interface:

isZero

Description: The function returns 1, if and only if its argument is ±0.

Calling interface:

```
int __binary32_isZero(float x);
int __binary64_isZero(double x);
```

isSubnormal

Description: The function returns 1, if and only if its argument is `subnormal`.

Calling interface:

```
int __binary32_isSubnormal(float x);
int __binary64_isSubnormal(double x);
```

isInfinite

Description: The function returns 1, if and only if its argument is `infinite`

Calling interface:

```
int __binary32_isInfinite(float x);
int __binary64_isInfinite(double x);
```

isNaN

Description: The function returns 1, if and only if its argument is a `NaN`.

Calling interface:

```
int __binary32_isNaN(float x);
int __binary64_isNaN(double x);
```

isSignaling

Description: The function returns 1, if and only if its argument is a signaling `NaN`.

Calling interface:

```
int __binary32_isSignaling(float x);
int __binary64_isSignaling(double x);
```

isCanonical

Description: The function returns 1, if and only if its argument is a finite number, `infinity`, or `NaN` that is canonical.

Calling interface:

```
int __binary32_isCanonical(float x);
int __binary64_isCanonical(double x);
```

NOTE
This function in this library always returns 1, as only canonical floating-point numbers are expected.

radix

Description: The function returns the radix of the format of the input floating-point number.

Calling interface:

```
int __binary32_radix(float x);
int __binary64_radix(double x);
```

NOTE
This function in this library always returns 2, as the library is intended for binary floating-point numbers.

totalOrder

Description: The function returns 1 if and only if two floating-point inputs `x` and `y` is total ordered and 0 otherwise.

Calling interface:

```
int _binary32_totalOrder(float x, float y);
int _binary64_totalOrder(double x, double y);
```

totalOrderMag

Description:`totalOrderMag(x, y)` is the same as `totalOrder(abs(x), abs(y))`.

Calling interface:

```
int _binary32_totalOrderMag(float x, float y);
int _binary64_totalOrderMag(double x, double y);
```

lowerFlags

Description: The function lowers the flags of the exception group specified by the input.

Value	Exception name
1	`__BFP754_INVALID`
2	`__BFP754_DIVBYZERO`
4	`__BFP754_OVERFLOW`
8	`__BFP754_UNDERFLOW`
16	`__BFP754_INEXACT`

Calling interface:

```
void __binary_lowerFlags(int x);
```

raiseFlags

Description: The function raises the flags of the exception group specified by the input.

Calling interface:

```
void __binary_raiseFlags(int x);
```

testFlags

Description: The function returns 1, if and only if any flag of the exception group specified by the input is raised, and 0 otherwise.

Calling interface:

```
int __binary_testFlags(int x);
```

testSavedFlags

Description: The function returns 1, if and only if any flag of the exception group specified by the input `y` is raised in `x`, and 0 otherwise.

Calling interface:

```
int __binary_testSavedFlags(int x, int y);
```

restoreFlags

Description: The function restores the flags to their states represented in `x`.

Calling interface:

```
void __binary_restoreFlags(int x);
```

saveFlags

Description: The function returns a representation of the state of all status flags.

Calling interface:

```
int __binary_saveFlags(void);
```

getBinaryRoundingDirection

Description: The function returns an integer representing the rounding direction in use.

Value	Exception name
0	`__BFP754_ROUND_TO_NEAREST_EVEN`
1	`__BFP754_ROUND_TOWARD_POSITIVE`
2	`__BFP754_ROUND_TOWARD_NEGATIVE`
3	`__BFP754_ROUND_TOWARD_ZERO`

Calling interface:

```
int __binary_getBinaryRoundingDirection(void);
```

setBinaryRoundingDirection

Description: The function sets the rounding direction based on input integer.

Calling interface:

```
void __binary_setBinaryRoundingDirection(int x);
```

saveModes

Description: The function saves the values of all dynamic-specifiable modes.

Calling interface:

```
int __binary_saveModes(void);
```

NOTE
`saveModes` behaves in the same way as `getBinaryRoundingDirection` does, as the rounding mode is the only dynamic-specifiable mode supported.

restoreModes

Description: The function restores the values of all dynamic-specifiable modes to the input.

Calling interface:
`int __binary_restoreModes(void);`

NOTE
`restoreModes` behaves in the same way as `setBinaryRoundingDirection` does, as the rounding mode is the only dynamic-specifiable mode supported.

defaultMode

Description: The function sets the values of all dynamic-specifiable modes to default.

Calling interface:
`void __binary_defaultMode(void);`

NOTE
`defaultMode` sets the rounding-direction attribute to `roundTiesToEven`, as the rounding mode is the only dynamic-specifiable mode supported.

Intel's Numeric String Conversion Library

Intel's Numeric String Conversion Library, `libistrconv`, provides a collection of routines for converting between ASCII strings and C data types, which are optimized for performance.

Product and Performance Information
Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex. Notice revision #20201201

Use Intel's Numeric String Conversion Library

Intel's Numeric String Conversion Library, `libistrconv`, provides a collection of routines for converting between ASCII strings and C data types, which are optimized for performance. The `istrconv.h` header file declares prototypes for the library functions.

You can link the `libistrconv` library as a static or shared library on Linux* and macOS platforms.On Windows* platforms, you must link `libistrconv` as a static library only.

Using Intel's Numeric String Conversion Library

To use the `libistrconv` library, include the header file, `istrconv.h`, in your program.

Consider the following example `conv.c` file that illustrates how to use the library to convert between string and floating-point data type.

```
// conv.c
#include <stdio.h>
#include <istrconv.h>
#define LENGTH 20

int main() {
 const char pi[] = "3.14159265358979323";
 char s[LENGTH];
 int prec;
 float fx;
 double dx;
 printf("PI: %s\n", pi);
 printf("single-precision\n");
 fx = __IML_string_to_float(pi, NULL);
 prec = 6;
 __IML_float_to_string(s, LENGTH, prec, fx);
 printf("prec: %2d, val: %s\n", prec, s);
 printf("double-precision\n");
 dx = __IML_string_to_double(pi, NULL);
 prec = 15;
 __IML_double_to_string(s, LENGTH, prec, dx);
 printf("prec: %2d, val: %s\n", prec, s);
 return 0;
}
```

To compile the `conv.c` file with Intel's Numeric String Conversion Library (`libistrconv`) use one of the following commands. See Invoke the Compiler for information about all available drivers.

Linux and macOS

```
icpc conv.c -libistrconv
```

Windows

```
icl conv.c libistrconv.lib
```

After you compile this example and run the program, you should get the following results:

```
PI: 3.14159265358979323

single-precision
prec: 6, val: 3.14159

double-precision
prec: 15, val: 3.14159265358979
```

Integer Conversion Functions Optimized with SSE4.2 Instructions

The following integer conversion functions are optimized for better performance with SSE4.2 string processing instructions:

- `__IML_int_to_string`
- `__IML_uint_to_string`
- `__IML_int64_to_string`
- `__IML_uint64_to_string`
- `__IML_i_to_str`
- `__IML_u_to_str`
- `__IML_ll_to_str`

- `__IML_ull_to_str`
- `__IML_string_to_int`
- `__IML_string_to_uint`
- `__IML_string_to_int64`
- `__IML_string_to_uint64`
- `__IML_str_to_i`
- `__IML_str_to_u`
- `__IML_str_to_ll`
- `__IML_str_to_ull`

The SSE4.2 optimized versions of these functions can be deployed in the following situations:

- Used automatically on post-SSE4.2 processors through Intel run-time processor dispatching
- Called directly by defining the "__SSE4_2__" macro to the C preprocessor where <istrconv.h> is included.

The generic versions of these functions can be deployed in the following situations:

- Used automatically on pre-SSE4.2 processors through Intel run-time processor dispatching
- Called directly by adding _generic suffix to the function names

The SSE4.2 optimized versions of these functions moves strings from memory to XMM registers and vice versa directly to maximize performance. The functions would not overwrite the memory beyond the boundary; however, this may introduce memory access violation when the memory location immediately trailing the strings is not allocated or accessible. Users with concerns about potential memory access violation should use the generic versions instead.

Function List

Intel's Numeric String Conversion library (`libistrconv`) functions are listed in this topic.

Routines to convert floating-point numbers to ASCII strings

Intel's Numeric String Conversion Library supports the following functions to convert floating-point number *x* to string *s* in various formats, where *l* represents the length of the formatted string allowing for full conversion (not including the null terminator).

`__IML_float_to_string`, `__IML_double_to_string`

Description: These functions are similar to `snprintf(s, n, "%.*g", p, x)` in `stdio.h`, where *p* specifies the maximum number of significant digits in either fixed-point or exponential notation format. If *n* is zero, nothing is written and *s* may be a null pointer. Output characters beyond the *(n-1)th* character are discarded and a null character is appended at the end. *l* is returned on success; otherwise the result is undefined.

Calling interface:

```
int __IML_float_to_string(char * s, size_t n, int p, float x);
```

```
int __IML_double_to_string(char * s, size_t n, int p, double x);
```

`__IML_float_to_string_f`, `__IML_double_to_string_f`

Description: These functions are similar to `snprintf(s, n, "%.*f", p, x)` in `stdio.h`, where *p* specifies the number of digits after the decimal point in the fixed-point notation format. If *n* is zero, nothing is written and *s* may be a null pointer. Output characters beyond the *(n-1)th* character are discarded and a null character is appended at the end. *l* is returned on success; otherwise the result is undefined.

Calling interface:

```
int __IML_float_to_string_f(char * s, size_t n, int p, float x);
```

```
int __IML_double_to_string_f(char * s, size_t n, int p, double x);
```

`__IML_float_to_string_e`, `__IML_double_to_string_e`

Description: These functions are similar to `snprintf(s, n, "%.*e", p, x)` in `stdio.h`, where *p* specifies the number of digits after the decimal point in the exponential notation format. If *n* is zero, nothing is written and *s* may be a null pointer. Output characters beyond the $(n\text{-}1)^{th}$ character are discarded and a null character is appended at the end. *l* is returned on success; otherwise, the result is undefined.

Calling interface:

```
int __IML_float_to_string_e(char * s, size_t n, int p, float x);
int __IML_double_to_string_e(char * s, size_t n, int p, double x);
```

`__IML_f_to_str`, `__IML_d_to_str`

Description: These functions are similar to `snprintf(s, n, "%.*g", p, x)` in `stdio.h`, where *p* specifies the maximum number of significant digits in either fixed-point or exponential notation format. If $l < n$, all output characters are stored in *s* with a null terminator at the end. Otherwise, output characters beyond the n^{th} character are discarded and no null character is appended at the end. If *n* is zero, nothing is written and *s* may be a null pointer. *l* is returned on success; otherwise the result is undefined.

Calling interface:

```
int __IML_f_to_str(char * s, size_t n, int p, float x);
int __IML_d_to_str(char * s, size_t n, int p, double x);
```

`__IML_f_to_str_f`, `__IML_d_to_str_f`

Description: These functions are similar to `snprintf(s, n, "%.*f", p, x)` in `stdio.h`, where *p* specifies the number of digits after the decimal point in the fixed-point notation format. If $l < n$, all output characters are stored in *s* with a null terminator at the end. Otherwise, output characters beyond the n^{th} character are discarded and no null character is appended at the end. If *n* is zero, nothing is written and *s* may be a null pointer. *l* is returned on success; otherwise the result is undefined.

Calling interface:

```
int __IML_f_to_str_f(char * s, size_t n, int p, float x);
int __IML_d_to_str_f(char * s, size_t n, int p, double x);
```

`__IML_f_to_str_e`, `__IML_d_to_str_e`

Description: These functions are similar to `snprintf(s, n, "%.*e", p, x)` in `stdio.h`, where *p*specifies the number of digits after the decimal point in the exponential notation format. If $l < n$, all output characters are stored in *s* with a null terminator at the end. Otherwise, output characters beyond the n^{th} character are discarded and no null character is appended at the end. If *n* is zero, nothing is written and *s* may be a null pointer. *l* is returned on success; otherwise the result is undefined.

Calling interface:

```
int __IML_f_to_str_e(char * s, size_t n, int p, float x);
int __IML_d_to_str_e(char * s, size_t n, int p, double x);
```

Routines to convert integers to ASCII strings

Intel's Numeric String Conversion Library supports the following functions to convert integer *x* to string *s*, where *l* represents the length of the formatted string allowing for full conversion (not including the null terminator).

`__IML_int_to_string`, `__IML_uint_to_string`, `__IML_int64_to_string`, `__IML_uint64_to_string`

Description: These functions are similar to `snprintf(s, n, "%[d|u|lld|llu]", x)` in `stdio.h`. If *n* is zero, nothing is written and *s* may be a null pointer. Output characters beyond the *(n-1)th* character are discarded and a null character is appended at the end. *l* is returned on success; otherwise the result is undefined.

Calling interface:

`int __IML_int_to_string(char * s, size_t n, int x);`

`int __IML_uint_to_string(char * s, size_t n, unsigned int x);`

`int __IML_int64_to_string(char * s, size_t n, long long x);`

`int __IML_uint64_to_string(char * s, size_t n, unsigned long long x);`

`__IML_int_to_oct_string`, `__IML_uint_to_oct_string`, `__IML_int64_to_oct_string`, `__IML_uint64_to_oct_string`

Description: These functions are similar to `snprintf(s, n, "%[o|llo]", x)` in `stdio.h`. If *n* is zero, nothing is written and *s* may be a null pointer. Output characters beyond the *(n-1)th* character are discarded and a null character is appended at the end. *l* is returned on success; otherwise the result is undefined.

Calling interface:

`int __IML_int_to_oct_string(char * s, size_t n, int x);`

`int __IML_uint_to_oct_string(char * s, size_t n, unsigned int x);`

`int __IML_int64_to_oct_string(char * s, size_t n, long long x);`

`int __IML_uint64_to_oct_string(char * s, size_t n, unsigned long long x);`

`__IML_int_to_hex_string`, `__IML_uint_to_hex_string`, `__IML_int64_to_hex_string`, `__IML_uint64_to_hex_string`

Description: These functions are similar to `snprintf(s, n, "%[x|llx]", x)` in `stdio.h`. If *n* is zero, nothing is written and *s* may be a null pointer. Output characters beyond the *(n-1)th* character are discarded and a null character is appended at the end. *l* is returned on success; otherwise the result is undefined.

Calling interface:

`int __IML_int_to_hex_string(char * s, size_t n, int x);`

`int __IML_uint_to_hex_string(char * s, size_t n, unsigned int x);`

`int __IML_int64_to_hex_string(char * s, size_t n, long long x);`

`int __IML_uint64_to_hex_string(char * s, size_t n, unsigned long long x);`

`__IML_i_to_str`, `__IML_u_to_str`, `__IML_ll_to_str`, `__IML_ull_to_str`

Description: These functions are similar to `snprintf(s, n, "%[d|u|lld|llu]", x)` in `stdio.h`. If *l* < *n*, all output characters are stored in *s* with a null terminator at the end. Otherwise, output characters beyond the *nth* character are discarded and no null character is appended at the end. If *n* is zero, nothing is written, and *s* may be a null pointer. *l* is returned on success, otherwise the result is undefined.

Calling interface:

`int __IML_i_to_str(char * s, size_t n, int x);`

`int __IML_u_to_str(char * s, size_t n, unsigned int x);`

`int __IML_ll_to_str(char * s, size_t n, long long x);`

`int __IML_ull_to_str(char * s, size_t n, unsigned long long x);`

`__IML_i_to_oct_str`, `__IML_u_to_oct_str`, `__IML_ll_to_oct_str`, `__IML_ull_to_oct_str`

Description: These functions are similar to `snprintf(s, n, "%[o|llo]", x)` in `stdio.h`. If *l* < *n*, all output characters are stored in *s* with a null terminator at the end. Otherwise, output characters beyond the n^{th} character are discarded and no null character is appended at the end. If *n* is zero, nothing is written, and *s* may be a null pointer. *l* is returned on success, otherwise the result is undefined.

Calling interface:

`int __IML_i_to_oct_str(char * s, size_t n, int x);`

`int __IML_u_to_oct_str(char * s, size_t n, unsigned int x);`

`int __IML_ll_to_oct_str(char * s, size_t n, long long x);`

`int __IML_ull_to_oct_str(char * s, size_t n, unsigned long long x);`

`__IML_i_to_hex_str`, `__IML_u_to_hex_str`, `__IML_ll_to_hex_str`, `__IML_ull_to_hex_str`

Description: These functions are similar to `snprintf(s, n, "%[x|llx]", x)` in `stdio.h`. If *l* < *n*, all output characters are stored in *s* with a null terminator at the end. Otherwise, output characters beyond the n^{th} character are discarded and no null character is appended at the end. If *n* is zero, nothing is written, and *s* may be a null pointer. *l* is returned on success, otherwise the result is undefined.

Calling interface:

`int __IML_i_to_hex_str(char * s, size_t n, int x);`

`int __IML_u_to_hex_str(char * s, size_t n, unsigned int x);`

`int __IML_ll_to_hex_str(char * s, size_t n, long long x);`

`int __IML_ull_to_hex_str(char * s, size_t n, unsigned long long x);`

Routines to convert ASCII strings to floating-point numbers

Intel's Numeric String Conversion Library supports the following functions to convert the initial portion of decimal string *s* to floating-point number *x*. If no conversion could be performed, zero is returned. If the correct value is outside the range of the return type, plus (+) or minus (-) `HUGE_VALF`, `HUGE_VAL`, or `HUGE_VALL` is returned, and the value of macro `ERANGE` is stored in `errno`.

`__IML_string_to_float`, `__IML_string_to_double`, `__IML_string_to_long_double`

Description: These functions are similar to `strtof(nptr, endptr)`, `strtod(nptr, endptr)`, and `strtold(nptr, endptr)` in `stdlib.h`, where *endptr* points to the object that stores the final part of *nptr* when *endptr* is not a null pointer.

Calling interface:

`float __IML_string_to_float(const char * nptr, char ** endptr);`

`double __IML_string_to_double(const char * nptr, char ** endptr);`

`long double __IML_string_to_long_double(const char * nptr, char ** endptr);`

`__IML_str_to_f`, `__IML_str_to_d`, `__IML_str_to_ld`

Description: These functions convert the initial *n* decimal digits of the *significand* string multiplied by 10 raised to power of *exponent* to floating-point number as return. *endptr* points to the object that stores the final part of significand, provided that *endptr* is not a null pointer.

Calling interface:

`float __IML_str_to_f(const char * significand, size_t n, int exponent, char ** endptr);`

double __IML_str_to_d(*const char * significand*, *size_t n*, *int exponent*, *char ** endptr*);

long double __IML_str_to_ld(*const char * significand*, *size_t n*, *int exponent*, *char ** endptr*);

Routines to convert ASCII strings to integers

Intel's Numeric String Conversion Library supports the following functions to convert the initial portion of string *s* to integer *x*. If no conversion could be performed, zero is returned. If the correct value is outside the range of the return type, `INT_MIN`, `INT_MAX`, `UINT_MAX`, `LLONG_MIN`, `LLONG_MAX`, `ULLONG_MAX` is returned, and the value of macro `ERANGE` is stored in `errno`.

`__IML_string_to_int`, `__IML_string_to_uint`, `__IML_string_to_int64`, `__IML_string_to_uint64`

Description: These functions are similar to `([unsigned] int)strto[u]l(nptr, endptr, 10)` and `strto[u]ll(nptr, endptr, 10)` functions in `stdlib.h`, where *endptr* points to the object that stores the final part of *nptr* when *endptr* is not a null pointer.

Calling interface:

int __IML_string_to_int(*const char * nptr*, *char ** endptr*);

unsigned int __IML_string_to_uint(*const char * nptr*, *char ** endptr*);

long long __IML_string_to_int64(*const char * nptr*, *char ** endptr*);

unsigned long long __IML_string_to_uint64(*const char * nptr*, *char ** endptr*);

`__IML_oct_string_to_int`, `__IML_oct_string_to_uint`, `__IML_oct_string_to_int64`, `__IML_oct_string_to_uint64`

Description: These functions are similar to `([unsigned] int)strto[u]l(nptr, endptr, 8)` and `strto[u]ll(nptr, endptr, 8)` functions in `stdlib.h`, where *endptr* points to the object that stores the final part of *nptr* when *endptr* is not a null pointer.

Calling interface:

int __IML_oct_string_to_int(*const char * nptr*,*char ** endptr*);

unsigned int __IML_oct_string_to_uint(*const char * nptr*,*char ** endptr*);

long long __IML_oct_string_to_int64(*const char * nptr*,*char ** endptr*);

unsigned long long __IML_oct_string_to_uint64(*const char * nptr*,*char ** endptr*);

`__IML_hex_string_to_int`, `__IML_hex_string_to_uint`, `__IML_hex_string_to_int64`, `__IML_hex_string_to_uint64`

Description: These functions are similar to `([unsigned] int)strto[u]l(nptr, endptr, 16)` and `strto[u]ll(nptr, endptr, 16)` functions in `stdlib.h`, where *endptr* points to the object that stores the final part of *nptr* when *endptr* is not a null pointer.

Calling interface:

int __IML_hex_string_to_int(*const char * nptr*,*char ** endptr*);

unsigned int __IML_hex_string_to_uint(*const char * nptr*,*char ** endptr*);

long long __IML_hex_string_to_int64(*const char * nptr*,*char ** endptr*);

unsigned long long __IML_hex_string_to_uint64(*const char * nptr*,*char ** endptr*);

`__IML_str_to_i`, `__IML_str_to_u`, `__IML_str_to_ll`, `__IML_str_to_ull`

Description: These functions convert the initial *n* decimal digits (including an optional + or - sign) pointed to by *nptr* to integral values. When *endptr* is not a null pointer it points to the object that stores the final part of *nptr*. These functions treat any leading whitespace as invalid.

Calling interface:

```
int __IML_str_to_i(const char * nptr, size_t n, char ** endptr);
unsigned int __IML_str_to_u(const char * nptr, size_t n, char ** endptr);
long long __IML_str_to_ll(const char * nptr, size_t n, char ** endptr);
unsigned long long __IML_str_to_ull(const char * nptr, size_t n, char ** endptr);
```

`__IML_oct_str_to_i, __IML_oct_str_to_u, __IML_oct_str_to_ll, __IML_oct_str_to_ull`

Description: These functions convert the initial *n* octal digits (including an optional + or - sign) pointed to by *nptr* to integral values. When *endptr* is not a null pointer it points to the object that stores the final part of *nptr*. These functions treat any leading whitespace as invalid.

Calling interface:

```
int __IML_oct_str_to_i(const char * nptr,size_t n,char ** endptr);
unsigned int __IML_oct_str_to_u(const char * nptr,size_t n,char ** endptr);
long long __IML_oct_str_to_ll(const char * nptr,size_t n,char ** endptr);
unsigned long long __IML_oct_str_to_ull(const char * nptr,size_t n,char ** endptr);
```

`__IML_hex_str_to_i, __IML_hex_str_to_u, __IML_hex_str_to_ll, __IML_hex_str_to_ull`

Description: These functions convert the initial *n* hexadecimal digits (including an optional + or - sign) pointed to by *nptr* to integral values. When *endptr* is not a null pointer it points to the object that stores the final part of *nptr*. These functions treat any leading whitespace as invalid.

Calling interface:

```
int __IML_hex_str_to_i(const char * nptr,size_t n,char ** endptr);
unsigned int __IML_hex_str_to_u(const char * nptr,size_t n,char ** endptr);
long long __IML_hex_str_to_ll(const char * nptr,size_t n,char ** endptr);
unsigned long long __IML_hex_str_to_ull(const char * nptr,size_t n,char ** endptr);
```

Macros

The Intel® C++ Compiler Classic supports the ISO Standard predefined macros and additional predefined macros.

ISO Standard Predefined Macros

The ISO/ANSI standard for the C language requires that certain predefined macros be supplied with conforming compilers.

The compiler includes predefined macros in addition to those required by the standard. The default predefined macros differ among Windows*, Linux*, and macOS operating systems due to the default `/Za` compiler option on Windows*. Differences also exist on Linux* and macOS as a result of the `-std` compiler option.

The following table lists the macros that the Intel® C++ Compiler supplies in accordance with this standard:

Macro	Value
`__DATE__`	The date of compilation as an 11-character string literal in the form `mm dd yyyy`. If the day is less than 10 characters, a space is added before the day value.
`__FILE__`	A string literal representing the name of the file being compiled.
`__LINE__`	The current line number as a decimal constant.
`__STDC__`	Defined when compiling a C translation unit with the `Za` compiler option. (Windows*)
`__STDC_HOSTED__`	Defined and value is 1 only when compiling a C translation unit with `/Qstd=c99`.
`__STDC_VERSION__`	Defined and value is 199901L only when compiling a C translation unit with `/Qstd=c99`.
`__STDC_WANT_DEC_FP__`	Defined when compiling with option `D`. (Windows*, Linux*) Define this macro and include the respective header files to get the functions, macros, and types that comprise support for decimal floating-point functionality.
`__TIME__`	The time of compilation as a string literal in the form `hh:mm:ss`.

See Also

Additional Predefined Macros

Additional Predefined Macros

The compiler supports the predefined macros listed in the table below. The compiler also includes predefined macros specified by the ISO/ANSI standard.

Unless otherwise stated, the macros are supported on systems based on IA-32 and Intel® 64 architectures. IA-32 is not available on macOS*.

NOTE
The Intel® C++ Compiler defines the same target-architecture macros that GCC does. For `-m feature`, GCC defines `__FEATURE__`.

You can target specific processor architectures by using the `-x`, `-m`, and `-march` compiler options. Each of these options enables feature-specific macros in the compiler. These macros are used to guard a section of application code that uses target-specific feature. The following command emits the list of predefined macros enabled by targeting a specific processor architecture:

```
icpc -dM -E helloworld.cc -xarch
```

For example, you could do the following to determine which feature macros would help identify whether this is ICELAKE-SERVER:

```
icpc -dM -E helloworld.cc -xSKYLAKE-AVX512 > avx512.txt 2>&1
icpc -dM -E helloworld.cc -xICELAKE-SERVER > icelake.txt 2>&1
diff avx512.txt icelake.txt
 317a318
 > #define AVX512IFMA 1
 320a322,329
 > #define AVX512VBMI 1
 > #define AVX512VPOPCNTDQ 1
 > #define AVX512BITALG 1
 > #define AVX512VBMI2 1
 > #define GFNI 1
 > #define VAES 1
 > #define VPCLMUL 1
 > #define AVX512VNNI 1
 321a331,334
 > #define RDPID 1
 > #define SGX 1
 > #define WBNOINVD 1
 > #define PCONFIG 1
```

The result of the `diff` command is the list of feature macros that can be used to differentiate `icelake-server` from `skylake-avx512`.

Macro	Description
`__APPLE__` (macOS)	Defined as '1'.
`__APPLE_CC__` (macOS)	The gcc* build number
`__ARRAY_OPERATORS` (Linux*)	Defined as '1'.
`__AVX__` (Windows*, Linux, macOS)	On Windows*, defined as '1' when option `/arch:AVX`, `/QxAVX`, or higher processor targeting options are specified. On Linux*, defined as '1' when option `-march=corei7-avx`, `-mavx`, `-xAVX`, or higher processor targeting options are specified.

Macro	Description
	NOTE Available only for compilations targeting Intel® 64 architecture.
`__AVX2__` (Windows, Linux, macOS)	On Windows, defined as '1' when option `/arch:CORE-AVX2`, `/QxCORE-AVX2`, or higher processor targeting options are specified. On Linux, defined as '1' when option `-march=core-avx2`, `-xCORE-AVX2`, or higher processor targeting options are specified. **NOTE** Available only for compilations targeting Intel® 64 architecture.
`__AVX512BW__` (Windows*, Linux, macOS)	Defined as '1' for processors that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Byte and Word instructions. It is also defined as '1' when option `[Q]xCORE-AVX512` or higher processor-targeting options are specified.
`__AVX512CD__` (Windows*, Linux, macOS)	Defined as '1' for processors that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Conflict Detection instructions. It is also defined as '1' when option `[Q]xCORE-AVX512`, `[Q]xCOMMON-AVX512`, or higher processor-targeting options are specified.
`__AVX512DQ__` (Windows*, Linux, macOS)	Defined as '1' for processors that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Doubleword and Quadword instructions. It is also defined as '1' when option `[Q]xCORE-AVX512` or higher processor-targeting options are specified.
`__AVX512ER__` (Windows*, Linux, macOS)	Defined as '1' for processors that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Exponential and Reciprocal instructions.
`__AVX512F__` (Windows*, Linux, macOS)	Defined as '1' for processors that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions. It is also defined as '1' when option `[Q]xCORE-AVX512`, `[Q]xCOMMON-AVX512`, or higher processor-targeting options are specified.
`__AVX512PF__` (Windows*, Linux, macOS)	Defined as '1' for processors that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Prefetch instructions.
`__AVX512VL__` (Windows*, Linux, macOS)	Defined as '1' for processors that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Vector Length extensions.

Macro	Description
	It is also defined as '1' when option `[Q]xCORE-AVX512` or higher processor-targeting options are specified.
`__BASE_FILE__` (Linux)	Name of source file
`_BOOL` (Linux)	Defined as '1'.
`__COUNTER__` (Windows)	Defined as '0'.
`__cplusplus` (Linux)	Defined as '1' (for the Intel® C++ Compiler).
`__DEPRECATED` (Linux)	Defined as '1'.
`__DYNAMIC__` (macOS)	Defined as '1'.
`__EDG__` (Windows, Linux, macOS)	Defined as '1'.
`__EDG_VERSION__` (Windows, Linux, macOS)	EDG version
`__ELF__` (Linux)	Defined as '1' at the start of compilation.
`__EXCEPTIONS` (Linux)	Defined as '1' when option `fno-exceptions` is *not* used.
`__gnu_linux__` (Linux)	Defined as '1' at the start of compilation.
`__GNUC__` (Linux)	The major version number of gcc* installed on the system or explicitly specified via `-gcc-name/ -gxx-name`.
`__GNUC_MINOR__` (Linux)	The minor version number of gcc* or g++* installed on the system or explicitly specified via `-gcc-name/ -gxx-name`.
`__GNUC_PATCHLEVEL__` (Linux)	The patch level version number of gcc* or g++* installed on the system or explicitly specified via `-gcc-name/ -gxx-name`.
`__GNUG__` (Linux)	The major version number of g++* installed on the system or explicitly specified via `-gcc-name/ -gxx-name`.
`__GXX_ABI_VERSION` (Linux)	The value of this is dependent on the -fabi-version option in effect.

Macro	Description
	102: -fabi-version=1 || gcc version < 3.4 1008: gcc version >= 5.0 999999: -fabi-version=0 100? Where ? matches the -fabi-version passed: -fabi-version=2,3,4,5,6,7,8,9 1002: Gcc version > 3.5 and < 5.0
`__HONOR_STD` (Linux, macOS)	Defined as '1'.

`__i386__`
`__i386`
`i386`
(Linux, macOS)
	Defined as '1' for compilations targeting IA-32 architecture. IA-32 is not available on macOS*.

`__ICC` (Linux, macOS)	The version of the compiler. **NOTE** This macro may be affected by compiler options, such as `-no-icc`.
`__ICL` (Windows)	The version of the compiler. **NOTE** This macro may be affected by compiler options, such as `/Qicl-`.
`_INC_STDIO` (Windows)	Defined, no value.
`_INTEGRAL_MAX_BITS` (Windows)	64
`__INTEL_COMPILER` (Windows*, Linux, macOS)	The version of the compiler. **NOTE** This macro may be affected by compiler options, such as `-no-icc`.
`__INTEL_COMPILER_BUILD_DATE` (Windows*, Linux, macOS)	The compiler build date. It takes the form YYYYMMDD, where *YYYY* is the year, *MM* is the month, and *DD* is the day.
`__INTEL_COMPILER_UPDATE` (Windows, Linux, macOS)	Returns the current minor update number of the compiler, starting at 0. You can use this macro to differentiate between compiler updates when you have multiple updates of the Intel® C++ Compiler installed concurrently. **Example:** For Intel® C++ Compiler version *XX.0.2*, the macro would preprocess to "2".

Macro	Description
`__INTEL_CXX11_MODE__` (Windows, Linux)	Enables C++11 experimental support for C++ programs. Defined as '1' when option `[Q]std=c++11` is specified.
`__INTEL_MS_COMPAT_LEVEL` (Windows)	Defined as '1'. Equal to the same value *n* as specified by option `[Q]ms`*n*.
`__INTEL_RTTI__` (Linux, macOS)	Defined as '1' when option `-fno-rtti` is *not* specified.
`__INTEL_STRICT_ANSI__` (Linux, macOS)	Defined as '1' when option `-strict-ansi` is specified.

`__linux__`
`__linux`
`linux`
(Linux)
	Defined as '1' at the start of compilation.

`__LITTLE_ENDIAN__` (macOS)	Defined as '1'.
`__LONG_DOUBLE_SIZE__` (Windows*, Linux, macOS)	On Linux and macOS, defined as 80. On Windows, defined as 64; defined as 80 when option `/Qlong-double` is specified.
`__LONG_DOUBLE_64__` (Linux)	When this macro is defined, the long double type is 64-bits. It is defined when you specify option `-mlong-double-64`.
`__LONG_MAX__` (Linux)	9223372036854775807L **NOTE** Available only for compilations targeting Intel® 64 architecture.
`__LP64__` (Linux) `__LP64` (Linux)	Defined as '1'. **NOTE** Available only for compilations targeting Intel® 64 architecture.
`_M_AMD64` (Windows)	Defined as '1' while building code targeting Intel® 64 architecture.
`_M_IX86` (Windows)	700

Macro	Description
_M_X64 (Windows)	Defined as '1' while building code targeting Intel® 64 architecture.
__MACH__ (macOS)	Defined as '1'.
__MMX__ (Linux, macOS)	Defined as '1'. On Linux, it is available only on systems based on Intel® 64 architecture.
_MSC_EXTENSIONS (Windows)	Defined as '1'. This macro is defined when Microsoft extensions are enabled.
_MSC_FULL_VER (Windows)	The Visual C++* version being used. 190022609 for Visual C++* 2015 1800210051 for Visual C++* 2013
_MSC_VER (Windows)	The Visual C++* version being used. 1900 for Visual C++* 2015 1800 for Visual C++* 2013
_MT (Windows)	On Windows, defined as '1' when a multithreaded DLL or library is used (when option `/MD[d]` or `/MT[d]` is specified).
__NO_INLINE__ __NO_MATH_INLINES __NO_STRING_INLINES (Linux, macOS)	Defined as '1'.
_OPENMP (Windows, Linux, macOS)	201611 when you specify option `[Q]openmp`.
__OPTIMIZE__ (Linux, macOS)	Defined as '1'.
__pentium4 __pentium4__ (Linux, macOS)	Defined as '1'.
_PGO_INSTRUMENT (Windows, Linux)	Defined as '1' when option `[Q]cov-gen` or `[Q]prof-gen` is specified.
__PIC__ __pic__ (Linux, macOS)	On Linux, defined as '1' when option `fPIC` is specified. On macOS, defined as '1'. Only `__PIC__` is allowed on macOS.
_PLACEMENT_DELETE (Linux)	Defined as '1'.

Macro	Description
`__PTRDIFF_TYPE__` (Linux, macOS)	On Linux, defined as int on IA-32 architecture; defined as long on Intel® 64 architecture. On macOS, defined as int/long.
`__QMSPP_` (Windows, macOS)	Defined as '1'.
`__REGISTER_PREFIX__` (Linux, macOS)	
`__SIGNED_CHARS__` (Windows, Linux, macOS)	Defined as '1'.
`_SIZE_T_DEFINED` (Windows)	Defined, no value.
`__SIZE_TYPE__` (Linux, macOS)	On Linux, defined as unsigned on IA-32 architecture; defined as unsigned long on Intel® 64 architecture. On macOS, defined as unsigned long.
`__SSE__` (Windows, Linux, macOS)	On Linux and macOS, defined as '1' for processors that support SSE instructions. On Windows, defined as '1'. It is undefined when option `/arch:IA32` is specified.
`__SSE2__` (Windows, Linux, macOS)	On Linux and macOS, defined as '1' for processors that support Intel® SSE2 instructions. On Windows, defined as '1' by default or when option `/arch:SSE2`, `/QxSSE2`, `/QaxSSE2`, or higher processor targeting options are specified.
`__SSE3__` (Windows, Linux, macOS)	On Linux and macOS, defined as '1' for processors that support Intel® SSE3 instructions. On Windows, defined as '1' when option `/arch:SSE3`, `/QxSSE3`, or higher processor targeting options are specified.
`__SSE4_1__` (Windows, Linux)	On Linux, defined as '1' for processors that support Intel® SSE4 instructions. On Windows, defined as '1' when option `/arch:SSE4.1`, `/QxSSE4.1`, or higher processor targeting options are specified.
`__SSE4_2__` (Windows, Linux)	On Linux, defined as '1' for processors that support SSSE4 instructions. On Windows, defined as '1' when option `/arch:SSE4.2`, `/QxSSE4.2`, or higher processor targeting options are specified.
`__SSSE3__` (Windows, Linux, macOS)	On Linux and macOS, defined as '1' for processors that support SSSE3 instructions.

Macro	Description
	On Windows, defined as '1' when option `arch:SSSE3`, `QxSSSE3`, or higher processor targeting options are specified.
`__STDC__` (macOS)	Defined as '1'.
`__STDC_HOSTED__` (macOS)	Defined as '1'.

`unix`
`__unix`
`__unix__`
(Linux)
	Defined as '1'.

`__USER_LABEL_PREFIX__` (Linux, macOS)	
`_VA_LIST_DEFINED` (Windows)	Defined, no value.
`__VERSION__` (Linux, macOS)	The compiler version string
`__w64` (Windows)	Defined, no value.
`__WCHAR_MAX__` (macOS)	2147483647
`__WCHAR_T` (Linux)	Defined as '1'.
`_WCHAR_T_DEFINED` (Windows)	Defined when option `/Zc:wchar_t` is specified or "*wctype_t*" is defined in the header file.
`__WCHAR_TYPE__` (Linux, macOS)	On Linux, defined as long int on IA-32 architecture; defined as int on Intel® 64 architecture. On macOS, defined as long int.
`_WCTYPE_T_DEFINED` (Windows)	Defined when "*wctype_t*" is defined in the header file.
`_WIN32` (Windows)	Defined as '1' while building code targeting IA-32 or Intel® 64 architecture. IA-32 is not available on macOS*.
`_WIN64` (Windows)	Defined as '1' while building code targeting Intel® 64 architecture.
`__WINT_TYPE__` (Linux, macOS)	Defined as unsigned int.

Macro	Description

`__x86_64`
`__x86_64__`
(Linux, macOS)
	Defined as '1' while building code targeting Intel® 64 architecture.

ISO Standard Predefined Macros

Use Predefined Macros to Specify Intel® Compilers

This topic shows how to use predefined macros to specify an Intel® compiler or version of an Intel compiler.

Predefined Macros to Specify Compiler and Version

When you install both the Intel® oneAPI Base Toolkit (Base Kit) and the Intel® oneAPI HPC Toolkit (HPC Kit), you will notice that there are three compilers installed:

- Intel® DPC++ Compiler
- Intel® C++ Compiler
- Intel® C++ Compiler Classic

NOTE This topic contains documentation for the Intel® C++ Compiler Classic. For information on predefined macros for the Intel® C++ Compiler and Intel® DPC++ Compiler, visit Predefined Macros for Intel® Compilers.

You can use the following predefined macros to invoke a specific compiler or version of a compiler:

Compiler	Predefined Macros to Differentiate from Other Compiler	Notes
Intel® C++ Compiler Classic	• `__INTEL_COMPILER` • `__INTEL_COMPILER_BUILD_DATE`	`__INTEL_COMPILER` is used to select the compiler. `__INTEL_COMPILER_BUILD_DATE` is used to select the compiler build.

Predefined Macros for Intel® C++ Compiler Classic

The following example uses `#if defined(__INTEL_COMPILER)` to define a code block specific to the Intel® C++ Compiler Classic:

```
// icc/icpc classic only
#if defined(__INTEL_COMPILER)
   // code specific for Intel C++ Compiler Classic below
```

```
   // ... ...

   // example only
   std::cout << "__INTEL_COMPILER_BUILD_DATE: " << __INTEL_COMPILER_BUILD_DATE << std::endl;
   std::cout << "__INTEL_COMPILER: " << __INTEL_COMPILER << std::endl;
   std::cout << "__VERSION__: " << __VERSION__ << std::endl;
#endif
```

Example output using the Intel® oneAPI Toolkit Gold release with an Intel C++ Compiler Classic patch release of 2021.1.2:

Linux

```
__INTEL_COMPILER_BUILD_DATE: 20201208

__INTEL_COMPILER: 2021

__VERSION__: Intel(R) C++ g++ 7.5 mode
```

Windows

```
__INTEL_COMPILER_BUILD_DATE: 20201208

__INTEL_COMPILER: 202110
```

Pragmas

Pragmas are directives that provide instructions to the compiler for use in specific cases. For example, you can use the `novector` pragma to specify that a loop should never be vectorized. The keyword `#pragma` is standard in the C++ language, but individual pragmas are machine-specific or operating system-specific, and vary by compiler.

Some pragmas provide the same functionality as compiler options. Pragmas override behavior specified by compiler options.

Some pragmas are available for both Intel® and non-Intel microprocessors but they may perform additional optimizations for Intel® microprocessors than they perform for non-Intel microprocessors. Refer to the individual pragma name for detailed description.

The Intel® C++ Compiler pragmas are categorized as follows:

- Intel-specific Pragmas - pragmas developed or modified by Intel to work specifically with the Intel® C++ Compiler
- Intel Supported Pragmas - pragmas developed by external sources that are supported by the Intel® C++ Compiler for compatibility reasons

Using Pragmas

You enter pragmas into your C++ source code using the following syntax:

```
#pragma <pragma name>
```

Individual Pragma Descriptions

Each pragma description has the following details:

Section	Description
Short Description	Contains a brief description of what the pragma does.

Section	Description
Syntax	Contains the pragma syntax.
Arguments	Contains a list of the arguments (parameters).
Description	Contains a detailed description of what the pragma does.
Example	Contains typical usage example/s.
See Also	Contains links or paths to other pragmas or related topics.

Intel-Specific Pragma Reference

Pragmas specific to the Intel® C++ Compiler Classic are listed in the following table.

Some pragmas are available for both Intel® microprocessors and non-Intel microprocessors, but may perform additional optimizations for Intel® microprocessors than for non-Intel microprocessors.

Pragma	Description
alloc_section	Allocates one or more variables in the specified section. Controls section attribute specification for variables.
block_loop/ noblock_loop	Enables or disables loop blocking for the immediately following nested loops. block_loop enables loop blocking for the nested loops. noblock_loop disables loop blocking for the nested loops.
code_align	Specifies the byte alignment for a loop
distribute_point	Instructs the compiler to prefer loop distribution at the location indicated.
inline/noinline/ forceinline	Specifies inlining of all calls in a statement. This also describes pragmas forceinline and noinline.
intel omp task	For Intel legacy tasking, specifies a unit of work, potentially executed by a different thread.
intel omp taskq	For Intel legacy tasking, specifies an environment for the while loop in which to queue the units of work specified by the enclosed `task` pragma.
ivdep	Instructs the compiler to ignore assumed vector dependencies.
loop_count	Specifies the iterations for a for loop.
nofusion	Prevents a loop from fusing with adjacent loops.
novector	Specifies that a particular loop should never be vectorized.
omp simd early_exit	Extends `#pragma omp simd`, allowing vectorization of multiple exit loops.
optimization_level	Controls optimization for one function or all functions after its first occurrence.
optimization_parameter	Passes certain information about a function to the optimizer.
optimize	Enables or disables optimizations for code after this pragma until another optimize pragma or end of the translation unit.
parallel/noparallel	Resolves dependencies to facilitate auto-parallelization of the immediately following loop (parallel) or prevents auto-parallelization of the immediately following loop (noparallel).

Pragma	Description
prefetch/noprefetch	Invites the compiler to issue or disable requests to prefetch data from memory. This pragma applies only to Intel® Advanced Vector Extensions 512 (Intel® AVX-512).
simd	Enforces vectorization of loops.
simdoff	Specifies a block of code in the SIMD loop or SIMD-enabled function that should be executed serially, in a logical order of SIMD lanes.
unroll/nounroll	Tells the compiler to unroll or not to unroll a counted loop.
unroll_and_jam/ nounroll_and_jam	Enables or disables loop unrolling and jamming. These pragmas can only be applied to iterative for loops.
unused	Describes variables that are unused (warnings not generated).
vector	Tells the compiler that the loop should be vectorized according to the argument keywords.

alloc_section

Allocates one or more variables in the specified section. Controls section attribute specification for variables.

Syntax

`#pragma alloc_section(`*`var1`*`,`*`var2`*`,...,` *`"r;attribute-list"`*`)`

Arguments

var	A variable that can be used to define a symbol in the section.
"r;attribute-list"	A comma-separated list of attributes; defined values are: '*short*' and '*long*'.

Description

The `alloc_section` pragma places the listed variables, *var1*, *var2*, etc., in the specified section. This pragma controls section attribute specification for variables. The compiler decides whether the variable, as defined by *var1*, *var2*, etc., should go to a "data", "bss", or "rdata" section.

The section name must be enclosed in double quotation marks. It should be previously introduced into the program using `#pragma section`. The list of comma-separated variable names follows the section name after a separating comma.

All listed variables must be defined before this pragma, in the same translation unit and in the same scope. The variables have static storage; their linkage does not matter in C modules, but in C++ modules they are defined with the extern "C" linkage specification.

Examples

This example shows how to use `#pragma alloc_section`:

```
#pragma alloc_section(var1, "r;short")
  int var1 = 20;
#pragma alloc_section(var2, "r;short")
  extern int var2;
```

block_loop/noblock_loop

Enables or disables loop blocking for the immediately following nested loops. block_loop enables loop blocking for the nested loops. noblock_loop disables loop blocking for the nested loops.

Syntax

`#pragma block_loop [`*`clause`*`[,`*`clause`*`]...]`

`#pragma noblock_loop`

Arguments

clause	Can be any of the following:	
	`factor` (*expr*)	*expr* is a positive scalar constant integer expression representing the blocking factor for the specified loops. This clause is optional. If the `factor` clause is not present, the blocking factor will be determined based on processor type and memory access patterns and will be applied to the specified levels in the nested loop following the pragma. At most only one *factor* clause can appear in a `block_loop` pragma.
	`level` (*level_expr*[, *level_expr*]...)	*level_expr* is specified in the form *const1* or *const1:const2* where *const1* is a positive integer constant *m*<= 8 representing the loop at level *m*, where the immediate following loop is level 1. The *const2* is a positive integer constant *n*<= 8 representing the loop at level *n*, where *n* > *m*. *const1:const2* represents the nested loops from level *const1* through *const2*.
	The clauses can be specified in any order. If you do not specify any clause, the compiler chooses the best blocking factor to apply to all levels of the immediately following nested loop.	

Description

The `block_loop` pragma lets you exert greater control over optimizations on a specific loop inside a nested loop.

Using a technique called loop blocking, the `block_loop` pragma separates large iteration counted loops into smaller iteration groups. Execution of these smaller groups can increase the efficiency of cache space use and augment performance.

If there is no `level` and `factor` clause, the blocking factor will be determined based on the processor's type and memory access patterns and it will apply to all the levels in the nested loops following this pragma.

You can use the `noblock_loop` pragma to tune the performance by disabling loop blocking for nested loops.

The loop-carried dependence is ignored during the processing of `block_loop` pragmas.

```
#pragma  block_loop factor(256) level(1)    /* applies blocking factor 256 to              */
#pragma  block_loop factor(512) level(2)    /* the top level loop in the following
                                               nested loop and blocking factor 512 to
                                               the 2nd level (1st nested) loop             */

#pragma  block_loop factor(256) level(2)
#pragma  block_loop factor(512) level(1)     /* levels can be specified in any order       */

#pragma  block_loop factor(256) level(1:2)   /* adjacent loops can be specified as a range  */

#pragma  block_loop factor(256)              /* the blocking factor applies to all levels
                                                of loop nest                                */

#pragma  block_loop               /* the blocking factor will be determined based on
                                     processor type and memory access patterns and will
                                     be applied to all the levels in the nested loop
                                     following the directive                                */

#pragma  noblock_loop             /* None of the levels in the nested loop following this
                                     directive will have a blocking factor applied          */
```

Consider the following:

```
#pragma block_loop factor(256) level(1:2)
for (j = 1 ; j<n ; j++){
  f  = 0 ;
  for (i =1 ;i<n  i++){
    f  =  f +   a[i]  *  b  [i] ;
  }
  c [j]  = c[j]  + f ;
}
```

The above code produces the following result after loop blocking:

```
for ( jj=1 ; jj<n/256+1 ; jj+){
  for ( ii = 1 ; ii<n/256+1 ;ii++){
    for ( j = (jj-1)*256+1 ;  min(jj*256, n) ;j++){
      f = 0 ;
      for ( i = (ii-1)*256+1 ;i<min(ii*256,n) ;i++){
        f = f + a[i] * b [i];
      }
      c[j]  = c[j] + f ;
    }
  }
}
```

code_align

Specifies the byte alignment for a loop

Syntax

`#pragma code_align`*(n)*

Arguments

n	Optional. A positive integer initialization expression indicating the number of bytes for the minimum alignment boundary. Its value must be a power of 2, between 1 and 4096, such as 1, 2, 4, 8, and so on. If you specify 1 for *n*, no alignment is performed. If you do not specify n, the default alignment is 16 bytes.

Description

This pragma must precede the loop to be aligned.

If the code is compiled with the `Qalign-loops:m` option, and a `code_align(n)` pragma precedes a loop, the loop is aligned on a max *(m, n)* byte boundary. If a procedure has the `code_align(k)` attribute and a `code_align(n)` pragma precedes a loop, then both the procedure and the loop are aligned on a max *(k, n)* byte boundary.

distribute_point

Instructs the compiler to prefer loop distribution at the location indicated.

Syntax

`#pragma distribute_point`

Arguments

None

Description

The `distribute_point` pragma is used to suggest to the compiler to split large loops into smaller ones; this is particularly useful in cases where optimizations like vectorization cannot take place due to excessive register usage.

The following rules apply to this pragma:

- When the pragma is placed inside a loop, the compiler distributes the loop at that point. All loop-carried dependencies are ignored.
- When inside the loop, pragmas cannot be placed within an `if` statement.
- When the pragma is placed outside the loop, the compiler distributes the loop based on an internal heuristic. The compiler determines where to distribute the loops and observes data dependency. If the pragmas are placed inside the loop, the compiler supports multiple instances of the pragma.

Examples

Use the `distribute_point` pragma outside the loop:

```
#define NUM 1024
void loop_distribution_pragma1(
       double a[NUM], double b[NUM], double c[NUM],
       double x[NUM], double y[NUM], double z[NUM] ) {
  int i;

  // Before distribution or splitting the loop
  #pragma distribute_point
  for (i=0; i< NUM; i++) {
    a[i] = a[i] + i;
    b[i] = b[i] + i;
```

```
    c[i] = c[i] + i;
    x[i] = x[i] + i;
    y[i] = y[i] + i;
    z[i] = z[i] + i;
  }
}
```

Use the `distribute_point` pragma inside the loop:

```
#define NUM 1024
void loop_distribution_pragma2(
       double a[NUM], double b[NUM], double c[NUM],
       double x[NUM], double y[NUM], double z[NUM] ) {
  int i;

  // After distribution or splitting the loop.
  for (i=0; i< NUM; i++) {
    a[i] = a[i] +i;
    b[i] = b[i] +i;
    c[i] = c[i] +i;
    #pragma distribute_point
    x[i] = x[i] +i;
    y[i] = y[i] +i;
    z[i] = z[i] +i;
  }
}
```

Use the `distribute_point` pragma inside and outside the loop:

```
void dist1(int a[], int b[], int c[], int d[]) {
  #pragma distribute_point
    // Compiler will automatically decide where to
    // distribute. Data dependency is observed.
  for (int i=1; i<1000; i++) {
    b[i] = a[i] + 1;
    c[i] = a[i] + b[i];
    d[i] = c[i] + 1;
  }
}

void dist2(int a[], int b[], int c[], int d[]) {
  for (int i=1; i<1000; i++) {
    b[i] = a[i] + 1;

    #pragma distribute_point
      // Distribution will start here,
      // ignoring all loop-carried dependency.
      c[i] = a[i] + b[i];
      d[i] = c[i] + 1;
  }
}
```

inline, noinline, forceinline

Specifies inlining of all calls in a statement. This also describes pragmas forceinline and noinline.

Syntax

```
#pragma inline [recursive]
```

```
#pragma forceinline [recursive]
```

```
#pragma noinline
```

Arguments

`recursive`	Indicates that the pragma applies to all of the calls that are called by these calls, recursively, down the call chain.

Description

`inline`, `forceinline`, and `noinline` are statement-specific inlining pragmas. Each can be placed before a C/C++ statement, and it will then apply to all of the calls within a statement and all calls within statements nested within that statement.

The `forceinline` pragma indicates that the calls in question should be inlined whenever the compiler is capable of doing so.

The `inline` pragma is a hint to the compiler that the user prefers that the calls in question be inlined, but expects the compiler not to inline them if its heuristics determine that the inlining would be overly aggressive and might slow down the compilation of the source code excessively, create too large of an executable, or degrade performance.

The `noinline` pragma indicates that the calls in question should not be inlined.

These statement-specific pragmas take precedence over the corresponding function-specific pragmas.

Examples

Use the `forceinline` recursive pragma:

```
#include <stdio.h>

static void fun(float a[100][100], float b[100][100]) {
  inti , j;
  for (i = 0; i < 100; i++) {
    for (j = 0; j < 100; j++) {
      a[i][j] = 2 * i;
      b[i][j] = 4 * j;
    }
  }
}

static void sun(float a[100][100], float b[100][100]) {
  int i, j;

  for (i = 0; i < 100; i++) {
    for (j = 0; j < 100; j++) {
      a[i][j] = 2 * i;
      b[i][j] = 4 * j;
    }
    fun(a, b);
  }
}
static float a[100][100];
static float b[100][100];

extern int main() {
  int i, j;
```

```
  for (i = 0; i < 100; i++) {
    for (j = 0; j < 100; j++) {
      a[i][j] = i + j;
      b[i][j] = i - j;
    }
  }
  for (i = 0; i < 99; i++) {
    fun(a, b);
#pragma forceinline recursive
    for (j = 0; j < 99; j++) {
      sun(a, b);
    }
  }
  fprintf(stderr, "%d %d\n", a[99][9], b[99][99]);
}
```

The `forceinline recursive` pragma applies to the call 'sun(a,b)' as well as the call 'fun(a,b)' called inside 'sun(a,b)'.

intel omp task

For Intel legacy tasking, specifies a unit of work, potentially executed by a different thread.

Syntax

`#pragma intel omp task [`*clause*`[[,]`*clause*`]...]`

`structured-block`

Arguments

clause	Can be any of the following:	
	`private` (*variable-list*)	Creates a private, default-constructed version for each object in *variable-list* for the `task`. The original object referenced by the variable has an indeterminate value upon entry to the construct, must not be modified within the dynamic extent of the construct, and has an indeterminate value upon exit from the construct.
	`captureprivate` (*variable-list*)	Creates a private, copy-constructed version for each object in *variable-list* for the `task` at the time the `task` is queued. The original object referenced by each variable retains its value but must not be modified within the dynamic extent of the `task` construct.

Description

The `intel omp task` pragma specifies a unit of work, potentially executed by a different thread.

NOTE
This pragma affects parallelization done using the `-qopenmp` option. Options that use OpenMP are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® vs. non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

intel omp taskq

For Intel legacy tasking, specifies an environment for the while loop in which to queue the units of work specified by the enclosed `task` pragma.

Syntax

`#pragma intel omp taskq[`*`clause`*`[[,]`*`clause`*`]...]`

`structured-block`

Arguments

clause

Can be any of the following:

`private` (*variable-list*)	Creates a private, default-constructed version for each object in *variable-list* for the `taskq`. It also implies `captureprivate` on each enclosed task. The original object referenced by each variable has an indeterminate value upon entry to the construct, must not be modified within the dynamic extent of the construct, and has an indeterminate value upon exit from the construct.
`firstprivate` (*variable-list*)	Creates a private, copy-constructed version for each object in *variable-list* for the `taskq`. It also implies `captureprivate` on each enclosed task. The original object referenced by each variable must not be modified within the dynamic extent of the construct and has an indeterminate value upon exit from the construct.
`lastprivate` (*variable-list*)	Creates a private, default-constructed version for each object in *variable-list* for the `taskq`. It also implies `captureprivate` on each enclosed task. The original object referenced by each variable has an indeterminate value upon entry to the construct, must not be modified within the dynamic extent of the construct, and is copy-

	assigned the value of the object from the last enclosed task after that task completes execution.
`reduction` (*operator* : *variable-list*)	Performs a reduction operation with the given operator in enclosed task constructs for each object in *variable-list*. *operator* and *variable-list* are defined the same as in the OpenMP* Specifications.
`ordered`	Organizes ordered constructs in enclosed `task` constructs in original sequential execution order. The `taskq` pragma, to which the `ordered` is bound, must have an `ordered` clause present.
`nowait`	Removes the implied barrier at the end of the `taskq`. Threads may exit the `taskq` construct before completing all the `task` constructs queued within it.

Description

The `intel omp taskq` pragma specifies the environment within which the enclosed units of work (tasks) are to be executed. From among all the threads that encounter a `intel omp taskq` pragma, one is chosen to execute it initially.

Conceptually, the `intel omp taskq` pragma causes an empty queue to be created by the chosen thread, and then the code inside the `taskq` block is executed as single-threaded. All the other threads wait for work to be queued on the conceptual queue.

The `intel omp taskq` pragma specifies a unit of work, potentially executed by a different thread. When a `task` pragma is encountered lexically within a `taskq` block, the code inside the `task` block is conceptually queued on the queue associated with the `taskq`. The conceptual queue is disbanded when all work queued on it finishes, and when the end of the `taskq` block is reached.

NOTE
This pragma affects parallelization done using the `Qopenmp` (Windows*) or `qopenmp` (Linux* or macOS) option. Options that use OpenMP* are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP* constructs and features that may perform differently on Intel® vs. non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

ivdep

Instructs the compiler to ignore assumed vector dependencies.

Syntax

```
#pragma ivdep
```

Arguments

None

Description

The `ivdep` pragma instructs the compiler to ignore assumed vector dependencies. To ensure correct code, the compiler treats an assumed dependence as a proven dependence, which prevents vectorization. This pragma overrides that decision. Use this pragma only when you know that the assumed loop dependencies are safe to ignore.

In addition to the `ivdep` pragma, the `vector` pragma can be used to override the efficiency heuristics of the vectorizer.

> **NOTE**
> The proven dependencies that prevent vectorization are not ignored, only assumed dependencies are ignored.

Examples

The loop in this example will not vectorize without the `ivdep` pragma, since the value of *k* is not known; vectorization would be illegal if `k < 0`:

```
void ignore_vec_dep(int *a, int k, int c, int m) {
  #pragma ivdep
  for (int i = 0; i < m; i++)
    a[i] = a[i + k] * c;
}
```

The pragma binds only the `for` loop contained in current function. This includes a `for` loop contained in a sub-function called by the current function:

```
#pragma ivdep
  for (i=1; i<n; i++) {
    e[ix[2][i]] = e[ix[2][i]]+1.0;
    e[ix[3][i]] = e[ix[3][i]]+2.0;
}
```

This loop requires the parallel option in addition to the `ivdep` pragma to indicate there is no loop-carried dependencies:

```
#pragma ivdep
  for (j=0; j<n; j++) { a[b[j]] = a[b[j]] + 1; }
```

This loop requires the parallel option in addition to the `ivdep` pragma to ensure there is no loop-carried dependency for the store into `a()`.

vector pragma

loop_count

Specifies the iterations for a for loop.

Syntax

`#pragma loop_count(`*n*`)`

`#pragma loop_count=`*`n`*

or

`#pragma loop_count(`*`n1`*`[, `*`n2`*`]...)`

`#pragma loop_count=`*`n1`*`[, `*`n2`*`]...`

or

`#pragma loop_count `*`min`*`(`*`n`*`),`*`max`*`(`*`n`*`),`*`avg`*`(`*`n`*`)`

`#pragma loop_count `*`min`*`=`*`n`*`, `*`max`*`=`*`n`*`, `*`avg`*`=`*`n`*

Arguments

(n) or =n	A non-negative integer value. The compiler will attempt to iterate the next loop the number of times specified in *n*; however, the number of iterations is not guaranteed.
(n1[,n2]...) or = n1[,n2]...	Non-negative integer values. The compiler will attempt to iterate the next loop the number of time specified by *n1* or *n2*, or some other unspecified number of times. This behavior allows the compiler some flexibility in attempting to unroll the loop. The number of iterations is not guaranteed.
min(n), max(n), avg(n) or min=n, max=n, avg=n	Non-negative integer values. Specify one or more in any order without duplication. The compiler insures the next loop iterates for the specified maximum, minimum, or average number (*n1*) of times. The specified number of iterations is guaranteed for min and max.

Description

The `loop_count` pragma specifies the minimum, maximum, or average number of iterations for a `for` loop. In addition, a list of commonly occurring values can be specified to help the compiler generate multiple versions and perform complete unrolling.

You can specify more than one pragma for a single loop; however, do not duplicate the pragma.

Examples

Use the `loop_count` pragma to iterate through the loop a minimum of three, a maximum of ten, and average of five times:

```
#include <stdio.h>
int i;
int mysum(int start, int end, int a) {
  int iret=0;
  #pragma loop_count min(3), max(10), avg(5)
    for (i=start;i<=end;i++)
    iret += a;
    return iret;
}

int main() {
  int t;
  t = mysum(1, 10, 3);
  printf("t1=%d\r\n",t);
```

```
  t = mysum(2, 6, 2);
  printf("t2=%d\r\n",t);
  t = mysum(5, 12, 1);
  printf("t3=%d\r\n",t);
}
```

nofusion

Prevents a loop from fusing with adjacent loops.

Syntax

`#pragma nofusion`

Arguments

None

Description

The `nofusion` pragma lets you fine tune your program on a loop-by-loop basis. This pragma should be placed immediately before the loop that should not be fused.

Examples

```
#define SIZE 1024

int sub () {
int B[SIZE], A[SIZE];
  int i, j, k=0;
  for(j=0; j<SIZE; j++)
    A[j] = A[j] + B[j];

#pragma nofusion
  for (i=0; i<SIZE; i++)
    k += A[i] + 1;
  return k;
}
```

novector

Specifies that a particular loop should never be vectorized.

Syntax

`#pragma novector`

Arguments

None

Description

The `novector` pragma specifies that a particular loop should never be vectorized, even if it is legal to do so. When avoiding vectorization of a loop is desirable (when vectorization results in a performance regression rather than improvement), the `novector` pragma can be used in the source text to disable vectorization of a loop. This behavior is in contrast to the `vector always` pragma.

Examples

Use the novector pragma:

```
void foo(int lb, int ub) {
  #pragma novector
  for(j=lb; j<ub; j++) { a[j]=a[j]+b[j]; }
}
```

When the trip count (ub - lb) is too low to make vectorization worthwhile, you can use the novector pragma to tell the compiler not to vectorize, even if the loop is considered vectorizable.

vector pragma

omp simd early_exit

Extends #pragma omp simd, allowing vectorization of multiple exit loops.

Syntax

```
#pragma omp simd early_exit
```

Description

Extends #pragma omp simd allowing vectorization of multiple exit loops. When this clause is specified:

- Each operation before last lexical early exit of the loop may be executed as if early exit were not triggered within the SIMD chunk.
- After the last lexical early exit of the loop, all operations are executed as if the last iteration of the loop was found.
- Each list item specified in the linear clause is computed based on the last iteration number upon exiting the loop.
- The last value for linear clauses and conditional lastprivates clauses are preserved with respect to scalar execution.
- The last value for reductions clauses are computed as if the last iteration in the last SIMD chunk was executed up on exiting the loop.
- The shared memory state may not be preserved with regard to scalar execution.
- Exceptions are not allowed.

Examples

The following example demonstrates how to use this pragma.

In the following example, the pragma specifies that the vector execution of the for loop is safe even though the loop may exit before the loop upper bound condition j < ub becomes false. Suppose j1 is the smallest j, between lb and ub, such that j satisfies b[j] <= 0 . If j1 and j1+1, j1+2, ... are within the same (last) SIMD chunk, read of b[j1], b[j1+1], b[j1+2], ... and the subsequent evaluation of <= 0 will happen unconditionally, unlike the scalar execution of the same loop. Safety of such vector evaluation is programmer's responsibility. If necessary, simdlen() clause can be used to control the SIMD chunk size.

```
void foo(int lb, int ub) {
  float a = 0;
  #pragma omp simd early_exit reduction(+:a)
      for(j=lb; j<ub; j++) {
          if (b[j] <= 0 )
              break;
```

```
            a += b[j];
      }
}
```

optimize

Enables or disables optimizations for code after this pragma until another optimize pragma or end of the translation unit.

Syntax

`#pragma optimize("", on|off)`

Arguments

The compiler ignores first argument values. Valid second arguments for `optimize` are:

off	Disables optimization
on	Enables optimization

Description

The `optimize` pragma is used to enable or disable optimizations.

Specifying `#pragma optimize("", off)` disables optimization until either the compiler finds a matching `#pragma optimize("", on)` statement or until the compiler reaches the end of the translation unit.

Examples

In this example, optimizations are disabled for the `alpha()` function but not for the `omega()` function:

```
#pragma optimize("", off)
  alpha() { ... }

#pragma optimize("", on)
  omega() { ... }
```

In this example, optimizations are disabled for both the `alpha()` and `omega()` functions:

```
#pragma optimize("", off)
  alpha() { ... }
  omega() { ... }
```

optimization_level

Controls optimization for one function or all functions after its first occurrence.

Syntax

`#pragma [intel|GCC] optimization_level n`

Arguments

intel|GCC	Indicates the interpretation to use
n	An integer value specifying an optimization level; valid values are:

- 0: same optimizations as option `-O0` (Linux* and macOS) or `/Od` (Windows*)
- 1: same optimizations as option `O1`
- 2: same optimizations as option `O2`
- 3: same optimizations as option `O3`

Description

The `optimization_level` pragma is used to restrict optimization for a specific function while optimizing the remaining application using a different, higher optimization level. For example, if you specify option level `O3` for the application and specify `#pragma optimization_level 1`, the marked function will be optimized at option level `O1`, while the remaining application will be optimized at the higher level.

In general, this pragma optimizes the function at the level specified as *n*; however, certain compiler optimizations, like Inter-procedural Optimization (IPO), are not enabled or disabled during translation unit compilation. For example, if you enable IPO and a specific optimization level, IPO is enabled even for the function targeted by this pragma; however, IPO might not be fully implemented regardless of the optimization level specified at the command line. The reverse is also true.

Scope of optimization restriction

On Linux* and macOS systems, the scope of the optimization restriction can be affected by arguments passed to the `-pragma-optimization-level` compiler option as explained in the following table.

Syntax	Behavior
`#pragma intel optimization_level` *n*	Applies the pragma only to the next function, using the specified optimization level, regardless of the argument passed to the `-pragma-optimization-level` option.
`#pragma GCC optimization_level` *n* or `#pragma GCC optimization_level reset`	Applies the pragma to all subsequent functions, using the specified optimization level, regardless of the argument passed to the `-pragma-optimization-level` option. Specifying `reset` reverses the effect of the most recent `#pragma GCC optimization_level` statement, by returning to the optimization level previously specified.
`#pragma optimization_level` *n*	Applies either the Intel® C++ Compiler Classic implementation or the GCC* interpretation. Interpretation depends on the argument passed to the `-pragma-optimization-level` option.

NOTE
On Windows* systems, the pragma always uses the `intel` interpretation; the pragma is applied only to the next function.

Examples

Place the pragma immediately before the function being affected.

This example shows the `intel` interpretation of the `optimization_level` pragma:

```
#pragma intel optimization_level 1
  gamma() { ... }
```

This example shows GCC* interpretation of the optimization_level pragma:

```
#pragma GCC optimization_level 1
  gamma() { ... }
```

optimization_parameter

Passes certain information about a function to the optimizer.

Syntax

Linux and macOS:

`#pragma intel optimization_parameter target_arch=<CPU>`

`#pragma intel optimization_parameter inline-max-total-size=n`

`#pragma intel optimization_parameter inline-max-per-routine=n`

Windows:

`#pragma [intel] optimization_parameter target_arch=<CPU>`

`#pragma [intel] optimization_parameter inline-max-total-size=n`

`#pragma [intel] optimization_parameter inline-max-per-routine=n`

Arguments

target_arch=*<CPU>*

For the list of CPUs, see compiler options -m (or /arch) and [Q]x.

inline-max-per-routine=*n*

Specifies the maximum number of times the inliner may inline into the routine. *n* is one of the following:

- A non-negative integer constant that specifies the maximum number of times the inliner may inline into the function. If you specify zero, no inlining is done into the function.
- The keyword unlimited, which means that there is no limit to the number of times the inliner may inline into the function.

For more information, see option [Q]inline-max-per-routine.

inline-max-total-size=*n*

Specifies how much larger a function can normally grow when inline expansion is performed. *n* is one of the following:

- A non-negative integer constant that specifies the permitted increase in the function's size when inline expansion is performed. If you specify zero, no inlining is done into the function.
- The keyword unlimited, which means that there is no limit to the size a function may grow when inline expansion is performed.

For more information, see option [Q]inline-max-total-size.

Description

The intel optimization_parameter target_arch pragma controls the -m (or /arch) option settings at the function level, overriding the option values specified at the command-line.

Place #pragma intel optimization_parameter target_arch=*<CPU>* at the head of a function to get the compiler to target that function for a specified instruction set. The pragma works like the -m (or /arch) and [Q]x options, but applies only to the function before which it is placed.

The pragmas `intel optimization_parameter inline-max-total-size=n` and `intel optimization_parameter inline-max-per-routine=n` specify information used during inlining into a function.

Examples

This example shows targeting code for Intel® Advanced Vector Extensions (Intel® AVX) processors:

```
For C++:
icc -mAVX foo.c   // on Linux andmacOS
 -mAVX foo.c   // on Linux and macOS
```

This example code targets just the function `bar` for Intel® AVX processors, regardless of the command line options used:

```
#pragma intel optimization_parameter target_arch=AVX
void bar() { ... }
```

compiler option

parallel/noparallel

Resolves dependencies to facilitate auto-parallelization of the immediately following loop (parallel) or prevents auto-parallelization of the immediately following loop (noparallel).

Syntax

`#pragma parallel [`*clause*`[ [,]`*clause*`]...]`

`#pragma noparallel`

Arguments

clause	Can be any of the following:	
	`always [assert]`	Overrides compiler heuristics that estimate whether parallelizing a loop would increase performance. Using this clause on a loop that the compiler finds to be parallelizable tells the compiler to parallelize the loop even if doing so might not improve performance.

	If `assert` is added, the compiler will generate an error-level assertion test to display a message saying that the compiler efficiency heuristics indicate that the loop cannot be vectorized.
`firstprivate` (*var* [:*expr*] ...)text	Provides a superset of the functionality provided by the `private` clause. Variables that appear in a `firstprivate` list are subject to `private` clause semantics. In addition, its initial value is broadcast to all private instances upon entering the parallel loop.
`lastprivate` (*var* [:*expr*] ...)	Provides a superset of the functionality provided by the `private` clause. Variables that appear in a `lastprivate` list are subject to private clause semantics. In addition, when the parallel region is exited, each variable has the value that results from the sequentially last iteration of the loop up exiting the parallel loop.
`num_threads` (*n*)	Parallelizes the loop across *n* threads, where *n* is an integer.
`private` (*var* [:*expr*] ...)	Specifies a list of scalar and array variables (*var*) to privatize. An array or pointer variable can take an optional argument (*expr*) which is an int32 or int64 expression denoting the number of array elements to privatize.

Like the `private` clause, both the `firstprivate`, and the `lastprivate` clauses specify a list of scalar and array variables (*var*) to privatize. An array or pointer variable can take an optional argument (expr) which is an int32 or int64 expression denoting the number of array elements to privatize.

The same *var* is not allowed to appear in both the `private` and the `lastprivate` clauses for the same loop.

The same *var* is not allowed to appear in both the `private` and the `firstprivate` clauses for the same loop.

When *expr* is absent, the rules on *var* are the same as with OpenMP. The rules to be observed are as follows:

- *var* must not be part of another variable (as an array or structure element)
- *var* must not have a `const`-qualified type unless it is of class type with a mutable member
- *var* must not have an incomplete type or a reference type
- if *var* is of class type (or array thereof), then it requires an accessible, unambiguous default constructor for the class type. Furthermore, if this *var* is in a `lastprivate` clause, then it also requires an accessible, unambiguous copy assignment operator for the class type.

When *expr* is present, the same rules apply, but *var* must be an array or a pointer variable.

- If *`var`* is an array, then only its first *expr* elements are privatized. Without *expr*, the entire array is privatized.
- If *var* is a pointer, then the first *expr* elements are privatized (element size given by the pointer's target type). Without *expr*, only the pointer variable itself is privatized.
- Program behavior is undefined if *expr* evaluates to a non-positive value, or if it exceeds the array size.

Description

The `parallel` pragma instructs the compiler to ignore potential dependencies that it assumes could exist and which would prevent correct parallelization in the immediately following loop. However, if dependencies are proven, they are not ignored.

The `noparallel` pragma prevents autoparallelization of the immediately following loop.

These pragmas take effect only if autoparallelization is enabled by the `[Q]parallel` compiler option. Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as the `arch`, `m`, or `[Q]x` compiler options.

Caution
Use this pragma with care. If a loop has cross-iteration dependencies, annotating it with this pragma can lead to incorrect program behavior.

Only use the `parallel` pragma if it is known that parallelizing the annotated loop will improve its performance.

Examples

This example shows how to use the `parallel` pragma:

```
void example(double *A, double *B, double *C, double *D) {
  int i;
  #pragma parallel
```

```
  for (i=0; i<10000; i++) {
    A[i] += B[i] + C[i];
    C[i] += A[i] + D[i];
  }
}
```

prefetch/noprefetch

Invites the compiler to issue or disable requests to prefetch data from memory. This pragma applies only to Intel® Advanced Vector Extensions 512 (Intel® AVX-512).

Syntax

`#pragma prefetch`

`#pragma prefetch *:hint[:distance]`

`#pragma prefetch [var1 [: hint1 [: distance1]] [, var2 [: hint2 [: distance2]]]...]`

`#pragma noprefetch [var1 [, var2]...]`

Arguments

var	An optional memory reference (data to be prefetched)
hint	An optional hint to the compiler to specify the type of prefetch. Possible values: • `1`: For integer data that will be reused • 2: For integer and floating point data that will be reused from L2 cache • `3`: For data that will be reused from L3 cache • `4`: For data that will not be reused To use this argument, you must also specify *var*.
distance	An optional integer argument with a value greater than 0. It indicates the number of loop iterations ahead of which a prefetch is issued, before the corresponding load or store instruction. To use this argument, you must also specify *var* and *hint*.

Description

The `prefetch` pragma hints to the compiler to generate data prefetches for some memory references. These hints affect the heuristics used in the compiler. Prefetching data can minimize the effects of memory latency.

If you specify the `prefetch` pragma with no arguments, all arrays accessed in the immediately following loop are prefetched.

If the loop includes the expression `A(j)`, placing `#pragma prefetch A` in front of the loop instructs the compiler to insert prefetches for `A(j + d)` within the loop. Here, *d* is the number of iterations ahead of which to prefetch the data, and is determined by the compiler.

If you specify `#pragma prefetch *`, then *hint* and *distance* prefetches all array accesses in the loop.

To use these pragmas, compiler option `[Q]opt-prefetch` must be set (it is turned on by default if the compiler general optimization level is set at option `O2` or higher).

The `noprefetch` pragma hints to the compiler not to generate data prefetches for some memory references. This affects the heuristics used in the compiler.

Examples

Use the `prefetch` pragma:

```
#pragma prefetch htab_p:1:30
#pragma prefetch htab_p:0:6

// Issue vprefetch1 for htab_p with a distance of 30 vectorized iterations ahead
// Issue vprefetch0 for htab_p with a distance of 6 vectorized iterations ahead
// If pragmas are not present, compiler chooses both distance values

for (j=0; j<2*N; j++) { htab_p[i*m1 + j] = -1; }
```

Use `noprefetch` and `prefetch` pragmas together:

```
#pragma noprefetch b
#pragma prefetch a
for(i=0; i<m; i++) { a[i]=b[i]+1; }
```

Use `noprefetch` and `prefetch` pragmas together:

```
for (i=i0; i!=i1; i+=is) {

float sum = b[i];
int ip = srow[i];
int c = col[ip];

#pragma noprefetch col
#pragma prefetch value:1:80
#pragma prefetch x:1:40

for(; ip<srow[i+1]; c=col[++ip])
  sum -= value[ip] * x[c];
  y[i] = sum;
}
```

simd

Enforces vectorization of loops.

Syntax

`#pragma simd [`*clause*`[ [,] `*clause*`]...]`

Arguments

clause	Can be any of the following:

`vectorlength` (*n1*[, *n2*]...)	Where *n* is a vector length (VL). It must be an integer that is a power of 2; the value must be 2, 4, 8, or 16. If you specify more than one *n*, the vectorizor will choose the VL from the values specified. Causes each iteration in the vector loop to execute the computation equivalent to *n* iterations of scalar loop execution. Multiple `vectorlength` clauses are merged as a union.
`vectorlengthfor` (*data type*)	Where *data type* must be one of built-in integer types (8-, 16-, 32-, or 64-bit), pointer types (treated as pointer-sized integer), floating point types (32- or 64-bit), or complex types (64- or 128-bit). Otherwise, behavior is undefined. Causes each iteration in the vector loop to execute the computation equivalent to *n* iterations of scalar loop execution where *n* is computed from `size_of_vector_register`/`sizeof(`*`data type`*`)`. For example, `vectorlengthfor(float)` results in `n=4` for Intel® Streaming SIMD Extensions (Intel® SSE2) to Intel SSE4.2 targets (packed float operations available on 128bit XMM registers) and `n=8` for an Intel® Advanced Vector Extensions (Intel® AVX) target (packed float operations available on 256bit YMM registers). `vectorlengthfor(int)` results in `n=4` for Intel SSE2 to Intel AVX targets. `vectorlength()` and `vectorlengthfor()` clauses are mutually exclusive. In other words, the `vectorlengthfor()` clause may not be used with the `vectorlength()` clause, and vice versa. Behavior for multiple `vectorlengthfor` clauses is undefined.
`private` (*var1*[, *var2*]...)	Where *var* is a scalar variable. Causes each variable to be private to each iteration of a loop. Unless the variable appears in `firstprivate` clause, the initial value of the variable for the particular iteration is undefined. Unless the variable appears in `lastprivate` clause, the value of the variable upon exit of the loop is undefined. Multiple `private` clauses are merged as a union.

	NOTE Execution of the SIMD loop with `firtsprivate`/`lastprivate` clauses may be different from serial execution of the same code even if the loop fails to vectorize. A variable in a `private` clause cannot appear in a `linear`, `reduction`, `firstprivate`, or `lastprivate` clause.
`firstprivate` (*var1*[, *var2*]...)	Provides a superset of the functionality provided by the `private` clause. Variables that appear in a `firstprivate` list are subject to `private` clause semantics. In addition, its initial value is broadcast to all private instances for each iteration upon entering the SIMD loop. A variable in a `firstprivate` clause can appear in a `lastprivate` clause. A variable in a `firstprivate` clause cannot appear in a `linear`, `reduction`, or `private` clause.
`lastprivate` (*var1*[, *var2*]...)	Provides a superset of the functionality provided by the `private` clause. Variables that appear in a `lastprivate` list are subject to `private` clause semantics. In addition, when the SIMD loop is exited, each variable has the value that resulted from the sequentially last iteration of the SIMD loop (which may be undefined if the last iteration does not assign to the variable). A variable in a `lastprivate` clause can appear in a `firstprivate` clause. A variable in a `lastprivate` clause cannot appear in a `linear`, `reduction`, or `private` clause.
`linear` (*var1:step1* [,*var2:step2*]...)	Where *var* is a scalar variable and *step* is a compile-time positive, integer constant expression. For each iteration of a scalar loop, *var1* is incremented by *step1*, *var2* is incremented by *step2*, and so on. Therefore, every iteration of the vector loop increments the variables by VL*step1, VL*step2, …, to VL*stepN, respectively. If more than one

	step is specified for a *var*, a compile-time error occurs. Multiple linear clauses are merged as a union. A variable in a `linear` clause cannot appear in a `reduction`, `private`, `firstprivate`, or `lastprivate` clause.
`reduction` (*oper:var1* [,*var2*]...)	Where *oper* is a reduction operator and *var* is a scalar variable. Applies the vector reduction indicated by *oper* to *var1*, *var2*, ..., *varN*. The `simd` pragma may have multiple reduction clauses with the same or different operators. If more than one reduction operator is associated with a *var*, a compile-time error occurs. A variable in a `reduction` clause cannot appear in a `linear`, `private`, `firstprivate`, or `lastprivate` clause.
`[no]assert`	Directs the compiler to assert or not to assert when the vectorization fails. The default is `noassert`. If this clause is specified more than once, a compile-time error occurs.
`[no]vecremainder`	Instructs the compiler to vectorize or not to vectorize the remainder loop when the original loop is vectorized. See the description of the vector pragma for more information.

Description

The `simd` pragma is used to guide the compiler to vectorize more loops. Vectorization using the `simd` pragma complements (but does not replace) the fully automatic approach.

Without explicit `vectorlength()` and `vectorlengthfor()` clauses, the compiler will choose a `vectorlength` using its own cost model. Misclassification of variables into `private`, `firstprivate`, `lastprivate`, `linear`, and `reduction`, or lack of appropriate classification of variables may cause unintended consequences such as runtime failures and/or incorrect result.

You can only specify a particular variable in at most one instance of a `private`, `linear`, or `reduction` clause.

If the compiler is unable to vectorize a loop, a warning will be emitted (use the `assert` clause to make it an error).

If the vectorizer has to stop vectorizing a loop for some reason, the fast floating-point model is used for the SIMD loop.

The vectorization performed on this loop by the `simd` pragma overrides any setting you may specify for options `-fp-model` (Linux* and macOS) and `/fp` (Windows*) for this loop.

Note that the `simd` pragma may not affect all auto-vectorizable loops. Some of these loops do not have a way to describe the SIMD vector semantics.

The following restrictions apply to the `simd` pragma:

- The countable loop for the `simd` pragma has to conform to the for-loop style of an OpenMP worksharing loop construct. Additionally, the loop control variable must be a signed integer type.
- The vector values must be signed 8-, 16-, 32-, or 64-bit integers, single or double-precision floating point numbers, or single or double-precision complex numbers.
- A SIMD loop may contain another loop (`for`, `while`, `do-while`) in it. Goto out of such inner loops are not supported. Break and continue are supported.

NOTE Inlining can create such an inner loop, which may not be obvious at the source level.

- A SIMD loop performs memory references unconditionally. Therefore, all address computations must result in valid memory addresses, even though such locations may not be accessed if the loop is executed sequentially.

To disable transformations that enables more vectorization, specify the `-vec -no-simd` (Linux* and macOS) or `/Qvec /Qno-simd` (Windows*) options.

User-mandated vectorization, also called SIMD vectorization can assert or not assert an error if a `#pragma simd` annotated loop fails to vectorize. By default, the `simd` pragma is set to `noassert`, and the compiler will issue a warning if the loop fails to vectorize. To direct the compiler to assert an error when the `#pragma simd` annotated loop fails to vectorize, add the `assert` clause to the `simd` pragma. If a `simd` pragma annotated loop is not vectorized by the compiler, the loop holds its serial semantics.

Examples

This example shows how to use the `simd` pragma:

```
 void add_floats(float *a, float *b, float *c, float *d, float *e, int n){
  int i;
#pragma simd
  for (i=0; i<n; i++){
    a[i] = a[i] + b[i] + c[i] + d[i] + e[i];
  }
}
```

In the example, the function `add_floats()` uses too many unknown pointers for the compiler's automatic runtime independence check optimization to kick-in. The programmer can enforce the vectorization of this loop by using the `simd` pragma to avoid the overhead of runtime check.

vector pragma

simdoff

Specifies a block of code in the SIMD loop or SIMD-enabled function that should be executed serially, in a logical order of SIMD lanes.

Syntax

`#pragma simdoff`

structured-block

Arguments

None.

Description

The `simdoff` block will use a single SIMD lane to execute operations in the order of the loop iterations, or logical lanes of a SIMD-enabled function. This preserves ordering of operations in the block with respect to each other, and correlates with iteration space of the enclosing SIMD construct. The ordered `simd` block is executed in order, with respect to each SIMD lane or each loop iteration. The operations within the ordered `simd` or `simdoff` block can be re-ordered by optimizations, as long as the original execution semantics are preserved.

`simdoff` blocks allow the isolation and resolution of situations prohibited from SIMD execution. This includes cross-iteration data dependencies, function calls with side effects, such as OpenMP, oneTBB and native thread synchronization primitives.

Examples

`simdoff` sections are useful for resolving cross-iteration data dependencies in otherwise data-parallel computations. For example, the section may handle histogram updates as shown in this example code:

```
#pragma simd
for (int i = 0; i < N; i++)
{
    float amount = compute_amount(i);
    int   cluster = compute_cluster(i);
#pragma simdoff
    {
       totals[cluster] += amount; // Requires ordering to process multiple updates for the same
cluster
    }
}
```

unroll/nounroll

Tells the compiler to unroll or not to unroll a counted loop.

Syntax

`#pragma unroll`

`#pragma unroll(`*n*`)`

`#pragma nounroll`

Arguments

n	The unrolling factor representing the number of times to unroll a loop; it must be an integer constant from 0 through 255.

Description

The `unroll`*[n]* pragma tells the compiler how many times to unroll a counted loop.

The `unroll` pragma must precede the `for` statement for each `for` loop it affects. If *n* is specified, the optimizer unrolls the loop *n* times. If *n* is omitted or if it is outside the allowed range, the optimizer assigns the number of times to unroll the loop.

This pragma is supported only when option `O3` is set. The `unroll` pragma overrides any setting of loop unrolling from the command line.

The pragma can be applied for the innermost loop nest as well as for the outer loop nest. If applied to outer loop nests, the current implementation supports complete outer loop unrolling. The loops inside the loop nest are either not unrolled at all or completely unrolled. The compiler generates correct code by comparing *n* and the loop count.

When unrolling a loop increases register pressure and code size it may be necessary to prevent unrolling of a loop. In such cases, use the `nounroll` pragma. The `nounroll` pragma instructs the compiler not to unroll a specified loop.

Examples

Use the `unroll` pragma for innermost loop unrolling:

```
void unroll(int a[], int b[], int c[], int d[]) {
  #pragma unroll(4)
  for (int i = 1; i < 100; i++) {
    b[i] = a[i] + 1;
    d[i] = c[i] + 1;
  }
}
```

Use the `unroll` pragma for outer loop unrolling:

```
int m = 0;
int dir[4]= {1,2,3,4};
int data[10];
#pragma unroll (4)  // outer loop unrolling
  for (int i = 0; i < 4; i++) {
     for (int j = dir[i]; data[j]==N ; j+=dir[i])
        m++;
  }
```

When you place the `unroll` pragma before the first `for` loop, it causes the compiler to unroll the outer loop completely. If an `unroll` pragma is placed before the inner `for` loop as well as before the outer `for` loop, the compiler ignores the inner `for` loop `unroll` pragma. If the `unroll` pragma is placed only for the innermost loop, the compiler unrolls the innermost loop according to some factor.

unroll_and_jam/nounroll_and_jam

Enables or disables loop unrolling and jamming. These pragmas can only be applied to iterative for loops.

Syntax

`#pragma unroll_and_jam`

`#pragma unroll_and_jam (`*n*`)`

`#pragma nounroll_and_jam`

Arguments

n	The unrolling factor representing the number of times to unroll a loop; it must be an integer constant from 0 through 255

Description

The `unroll_and_jam` pragma partially unrolls one or more loops higher in the nest than the innermost loop and fuses/jams the resulting loops back together. This transformation allows more reuses in the loop.

This pragma is not effective on innermost loops. Ensure that the immediately following loop is not the innermost loop after compiler-initiated interchanges are completed.

Specifying this pragma is a hint to the compiler that the unroll and jam sequence is legal and profitable. The compiler enables this transformation whenever possible.

The `unroll_and_jam` pragma must precede the `for` statement for each `for` loop it affects. If *n* is specified, the optimizer unrolls the loop *n* times. If *n* is omitted or if it is outside the allowed range, the optimizer assigns the number of times to unroll the loop. The compiler generates correct code by comparing *n* and the loop count.

This pragma is supported only when compiler option `O3` is set. The `unroll_and_jam` pragma overrides any setting of loop unrolling from the command line.

When unrolling a loop increases register pressure and code size it may be necessary to prevent unrolling of a nested loop or an imperfect nested loop. In such cases, use the `nounroll_and_jam` pragma. The `nounroll_and_jam` pragma hints to the compiler not to unroll a specified loop.

Examples

Use the `unroll_and_jam` pragma:

```
int a[10][10];
int b[10][10];
int c[10][10];
int d[10][10];
void unroll(int n) {
    int i,j,k;
    #pragma unroll_and_jam (6)
    for (i = 1; i < n; i++) {
       #pragma unroll_and_jam (6)
       for (j = 1; j < n; j++) {
          for (k = 1; k < n; k++){
            a[i][j] += b[i][k]*c[k][j];
            }
       }
    }
}
```

unused

Describes variables that are unused (warnings not generated).

Syntax

`#pragma unused`

Arguments

None

Description

The `unused` pragma is implemented for compatibility with Apple* implementation of GCC.

vector

Tells the compiler that the loop should be vectorized according to the argument keywords.

Syntax

```
#pragma vector {always[assert]|aligned|unaligned|dynamic_align|nodynamic_align|[no]
multiple_gather_scatter_by_shuffles|temporal|nontemporal|[no]vecremainder|
[no]mask_readwrite|vectorlength(n1[, n2]...)}
```

```
#pragma vector nontemporal[(var1[, var2, ...])]
```

Arguments

`always`	Instructs the compiler to override any efficiency heuristic during the decision to vectorize or not, and vectorize non-unit strides or very unaligned memory accesses; controls the vectorization of the subsequent loop in the program; optionally takes the keyword assert.
`aligned`	Instructs the compiler to use aligned data movement instructions for all array references when vectorizing.
`unaligned`	Instructs the compiler to use unaligned data movement instructions for all array references when vectorizing.
`dynamic_align`[(*var*)]	Instructs the compiler to perform dynamic alignment optimization for the loop with an optionally specified variable to perform alignment on.
`nodynamic_align`	Disables dynamic alignment optimization for the loop.
`multiple_gather_scatter_by_shuffles`	Instructs the optimizer to disable the generation of gather/scatter and to transform gather/scatter into unit-strided loads/stores plus a set of shuffles wherever possible.
`nomultiple_gather_scatter_by_shuffles`	Instructs the optimizer to enable the generation of gather/scatter instructions and not to transform gather/scatter into unit-strided loads/stores.
`nontemporal`	Instructs the compiler to use non-temporal (that is, streaming) stores on systems based on all supported architectures, unless otherwise specified; optionally takes a comma-separated list of variables. When this pragma is specified, it is your responsibility to also insert any fences as required to ensure correct memory ordering within a thread or across threads. One typical way to do this is to insert a `_mm_sfence` intrinsic call just after the loops (such as the initialization loop) where the compiler may insert streaming store instructions.

`temporal`	Instructs the compiler to use temporal (that is, non-streaming) stores on systems based on all supported architectures, unless otherwise specified.
`vecremainder`	Instructs the compiler to vectorize the remainder loop when the original loop is vectorized.
`novecremainder`	Instructs the compiler not to vectorize the remainder loop when the original loop is vectorized.
`mask_readwrite`	Disables memory speculation, causing the generation of masked load and store operations within conditions.
`nomask_readwrite`	Enables memory speculation, causing the generation of non-masked loads and stores within conditions.
`vectorlength` (*n1*[, *n2*]...)	Instructs the vectorizer which vector length/factor to use when generating the main vector loop.

Description

The `vector` pragma indicates that the loop should be vectorized, if it is legal to do so, ignoring normal heuristic decisions about profitability. The `vector` pragma takes several argument keywords to specify the kind of loop vectorization required. The compiler does not apply the `vector` pragma to nested loops, each nested loop needs a preceding pragma statement. Place the pragma before the loop control statement.

Using the `aligned/unaligned` keywords

When the `aligned/unaligned` argument keyword is used with this pragma, it indicates that the loop should be vectorized using aligned/unaligned data movement instructions for all array references. Specify only one argument keyword: `aligned` or `unaligned`.

> **Caution**
> If you specify `aligned` as an argument, you must be sure that the loop is vectorizable using this pragma. Otherwise, the compiler generates incorrect code.

Using the `always` keyword

When the `always` argument keyword is used, the pragma will ignore compiler efficiency heuristics for the subsequent loop. When `assert` is added, the compiler will generate a diagnostic message if the loop cannot be vectorized for any reason.

Using the `dynamic_align` and `nodynamic_align` keywords

Dynamic alignment is an optimization the compiler attempts to perform by default. It involves peeling iterations from the vector loop into a scalar loop before the vector loop so that the vector loop aligns with a particular memory reference. The `dynamic_align` (*var*) form of the directive allows the user to provide a scalar or array variable name to align on. Specifying `nodynamic_align` with or without *var* does not guarantee the optimization is performed; the compiler still uses heuristics to determine feasibility of the operation.

Using the `multiple_gather_scatter_by_shuffles` and `nomultiple_gather_scatter_by_shuffles` keywords

These clauses do not affect loops nested in the specified loop.

Using the `nontemporal` and `temporal` keywords

The nontemporal and temporal argument keywords are used to control how the "stores" of register contents to storage are performed (streaming versus non-streaming) on systems based on IA-32 and Intel® 64 architectures.

By default, the compiler automatically determines whether a streaming store should be used for each variable.

Streaming stores may cause significant performance improvements over non-streaming stores for large numbers on certain processors. However, the misuse of streaming stores can significantly degrade performance.

Using the `[no]vecremainder` keyword

If the vector always pragma and keyword are specified, the following occurs:

- If the vecremainder clause is specified, the compiler vectorizes both the main and remainder loops.
- If the novecremainder clause is specified, the compiler vectorizes the main loop, but it does not vectorize the remainder loop.

Using the `[no]mask_readwrite` keyword

If the vector pragma and mask_readwrite or nomask_readwrite keyword are specified, the following occurs:

- If the mask_readwrite clause is specified, the compiler generates masked loads and stores within all conditions in the loop.
- If the nomask_readwrite clause is specified, the compiler generates unmasked loads and stores for increased performance.

Using the `vectorlength` keyword

n is an integer power of 2; the value must be 2, 4, 6, 8, 16, 32, or 64. If more than one value is specified, the vectorizer will choose one of the specified vector lengths based on a cost model decision.

NOTE
The pragma vector should be used with care.

Overriding the efficiency heuristics of the compiler should only be done if the programmer is absolutely sure that vectorization will improve performance. Furthermore, instructing the compiler to implement all array references with aligned data movement instructions will cause a run-time exception in case some of the access patterns are actually unaligned.

Examples

Use the `vector aligned` pragma

In the following example, the aligned argument keyword is used to request that the loop be vectorized with aligned instructions.

Note that the arrays are declared in such a way that the compiler could not normally prove this would be safe to vectorize.

```
void vec_aligned(float *a, int m, int c) {
  int i;
  // Instruct compiler to ignore assumed vector dependencies.
  #pragma vector aligned
  for (i = 0; i < m; i++)
    a[i] = a[i] * c;
  // Alignment unknown but compiler can still align.
```

```
  for (i = 0; i < 100; i++)
    a[i] = a[i] + 1.0f;
}
```

Use the `vector always` pragma

```
void vec_always(int *a, int *b, int m) {
  #pragma vector always
  for(int i = 0; i <= m; i++)
    a[32*i] = b[99*i];
}
```

Use the `vector multiple gather type` pragma

```
float sum=0.0f;
#pragma omp simd reduction(+:sum)
for (i=0; i<N; i++){
   sum += A[3*i+0] + A[3*i+1] + A[3*i+2];
}
```

Use the `vector nontemporal` pragma

```
float a[1000];
void foo(int N){
  int i;
  #pragma vector nontemporal
  for (i = 0; i < N; i++) {
    a[i] = 1;
  }
}
```

Use ASM code for the loop body

A float-type loop together with the generated assembly is shown in the following example. For large *N*, significant performance improvements result on systems with Intel® Pentium® 4 processors over non-streaming implementations.

```
  .B1.2:
movntps XMMWORD PTR _a[eax], xmm0
movntps XMMWORD PTR _a[eax+16], xmm0
add eax, 32
cmp eax, 4096
jl .B1.2
```

Use pragma `vector nontemporal` with variables for implementing streaming stores

```
double A[1000];
double B[1000];
void foo(int n){
  int i;
#pragma vector nontemporal (A, B)
  for (i=0; i<n; i++){
    A[i] = 0;
    B[i] = i;
  }
}
```

Intel-supported Pragma Reference

The Intel® C++ Compiler Classic supports the following pragmas to ensure compatibility with other compilers.

Pragmas Compatible with the Microsoft* Compiler

The following pragmas are compatible with the Microsoft Compiler. For more information about these pragmas, go to the Microsoft Developer Network (http://msdn.microsoft.com).

Pragma	Description
`alloc_text`	Names the code section where the specified function definitions are to reside.
`auto_inline`	Excludes any function defined within the range where **`off`** is specified from being considered as candidates for automatic inline expansion.
`bss_seg`	Indicates to the compiler the segment where uninitialized variables are stored in the `.obj` file.
`check_stack`	The **`on`** argument indicates that stack checking should be enabled for functions that follow and the **`off`** argument indicates that stack checking should be disabled for functions that follow.
`code_seg`	Specifies a code section where functions are to be allocated.
`comment`	Places a comment record into an object file or executable file.
`component`	Controls collecting of browse information or dependency information from within source files.
`conform`	Specifies the run-time behavior of the `/Zc:`*`forScope`* compiler option.
`const_seg`	Specifies the segment where functions are stored in the `.obj` file.
`data_seg`	Specifies the default section for initialized data.
`deprecated`	Indicates that a function, type, or any other identifier may not be supported in a future release or indicates that a function, type, or any other identifier should not be used any more.
`fenv_access`	Informs an implementation that a program may test status flags or run under a non-default control mode.
`float_control`	Specifies floating-point behavior for a function.
`fp_contract`	Allows or disallows the implementation to contract expressions.
`loop`	Controls how the loop code will be considered or excluded from consideration by the auto-vectorizer.
`init_seg`	Specifies the section to contain C++ initialization code for the translation unit.
`message`	Displays the specified string literal to the standard output device (`stdout`).

Pragma	Description
`optimize`	Specifies optimizations to be performed on functions below the pragma or until the next optimize pragma; implemented to partly support the Microsoft implementation of same pragma; for the Intel® C++ Compiler Classic implementation, see the `optimize` reference page.
`pointers_to_members`	Specifies whether a pointer to a class member can be declared before its associated class definition and is used to control the pointer size and the code required to interpret the pointer.
`pop_macro`	Sets the value of the specified macro to the value on the top of the stack.
`push_macro`	Saves the value of the specified macro on the top of the stack.
`region/endregion`	Specifies a code segment in the Microsoft Visual Studio* Code Editor that expands and contracts by using the outlining feature.
`section`	Creates a section in an `.obj` file. Once a section is defined, it remains valid for the remainder of the compilation.
`vtordisp`	The **`on`** argument enables the generation of hidden `vtordisp` members and the **`off`** disables them. **`push`** argument pushes the current `vtordisp` setting to the internal compiler stack. **`pop`** argument removes the top record from the compiler stack and restores the removed value of `vtordisp`.
`warning`	Allows selective modification of the behavior of compiler warning messages.
`weak`	Declares symbol you enter to be weak.

OpenMP* Standard Pragmas

The Intel® C++ Compiler Classic currently supports OpenMP* 5.0 Version TR4, and some OpenMP Version 5.1 pragmas. Supported pragmas are isted below. For more information about these pragmas, reference the OpenMP* Version 5.1 specification.

Intel-specific clauses are noted in the affected pragma description.

Pragma	Description
omp atomic	Specifies a computation that must be executed atomically.
omp barrier	Specifies a point in the code where each thread must wait until all threads in the team arrive.
omp cancel	Requests cancellation of the innermost enclosing region of the type specified, and causes the encountering task to proceed to the end of the cancelled construct.
omp cancellation point	Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified. This construct does not implement a synchronization between threads or tasks.
omp critical	Specifies a code block that is restricted to access by only one thread at a time.

Pragma	Description
omp declare reduction	Declares User-Defined Reduction (UDR) functions (reduction identifiers) that can be used as reduction operators in a reduction clause.
omp declare simd	Creates a version of a function that can process multiple arguments using Single Instruction Multiple Data (SIMD) instructions from a single invocation from a SIMD loop.
omp distribute	Specifies that the iterations of one or more loops should be distributed among the initial threads of all thread teams in a league.
omp distribute parallel for	Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.
omp distribute parallel for simd	Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.
omp distribute simd	Specifies a loop that will be distributed across the primary threads of the teams region. It will be executed concurrently using SIMD instructions.
omp flush	Identifies a point at which a thread's temporary view of memory becomes consistent with the memory.
omp for	Specifies a work-sharing loop. Iterations of the loop are executed in parallel by the threads in the team.
omp for simd	Specifies that the iterations of the loop will be distributed across threads in the team. Iterations executed by each thread can also be executed concurrently using SIMD instructions.
omp master	Specifies a code block that must be executed only once by the primary thread of the team.
omp ordered	Specifies a block of code that the threads in a team must execute in the natural order of the loop iterations, or as a stand-alone directive, specifies cross-iteration dependences in a doacross loop-nest.
omp parallel	Specifies that a structured block should be run in parallel by a team of threads.
omp parallel for	Provides an abbreviated way to specify a parallel region containing only a FOR construct.
omp parallel for simd	Specifies a parallel construct that contains one for simd construct and no other statement.
omp parallel sections	Specifies a parallel construct that contains only a sections construct.
omp scan	Specifies a scan computation that updates each list item in each iteration of the loop.
omp sections	Defines a set of structured blocks that will be distributed among the threads in the team.
omp simd	Transforms the loop into a loop that will be executed concurrently using SIMD instructions.
omp single	Specifies that a block of code is to be executed by only one thread in the team.

Pragma	Description
omp target	Creates a device data environment and executes the construct on that device.
omp target data	Specifies that variables are mapped to a device data environment for the extent of the region.
omp target enter data	Specifies that variables are mapped to a device data environment.
omp target exit data	Specifies that variables are unmapped from a device data environment.
omp target teams	Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the primary thread in each team executing the structured block.
omp target teams distribute	Creates a device data environment and then executes the construct on that device. It also specifies that loop iterations will be distributed among the primary threads of all thread teams in a league created by a teams construct.
omp target teams distribute parallel for	Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a teams construct.
omp target teams distribute parallel for simd	Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a teams construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions.
omp target teams distribute simd	Creates a device data environment and then executes the construct on that device. It also specifies that loop iterations will be distributed among the primary threads of all thread teams in a league created by a teams construct. It will be executed concurrently using SIMD instructions.
omp target update	Makes the items listed in the device data environment consistent between the device and host, in accordance with the motion clauses on the pragma.
omp task	Specifies a code block whose execution may be deferred.
omp taskgroup	Causes the program to wait until the completion of all enclosed and descendant tasks.
omp taskwait	Specifies a wait on the completion of child tasks generated since the beginning of the current task.
omp taskyield	Specifies that the current task can be suspended at this point in favor of execution of a different task.
omp teams	Creates a league of thread teams inside a target region to execute a structured block in the initial thread of each team.
omp teams distribute	Creates a league of thread teams and specifies that loop iterations will be distributed among the primary threads of all thread teams in the league.
omp teams distribute parallel for	Creates a league of thread teams and specifies that the associated loop can be executed in parallel by multiple threads that are members of multiple teams.

Pragma	Description
omp teams distribute parallel for simd	Creates a league of thread teams and specifies that the associated loop can be executed concurrently using SIMD instructions in parallel by multiple threads that are members of multiple teams.
omp teams distribute simd	Creates a league of thread teams and specifies that the associated loop will be distributed across the primary threads of the teams and executed concurrently using SIMD instructions.
omp threadprivate	Specifies a list of globally-visible variables that will be allocated private to each thread.

Pragmas Compatible with Other Compilers

The following pragmas are compatible with other compilers. For more information about these pragmas, see the documentation for the specified compiler.

Pragma	Description
`include_directory`	HP-compatible pragma. It appends the string argument to the list of places to search for `#include` files.
`poison`	GCC-compatible pragma. It labels the identifiers you want removed from your program; an error results when compiling a "`poisoned`" `identifier; #pragma POISON` is also supported.
`options`	GCC-compatible pragma; It sets the alignment of fields in structures.
`weak`	GCC-compatible pragma, it declares the symbol you enter to be weak.

Zc compiler option

Error Handling

This topic describes compiler remarks, warnings, and errors. The compiler sends these messages, along with the erroneous source line, to stderr.

Warnings

Warning messages report legal but questionable use of C or C++. The compiler displays warnings by default. You can suppress warning messages by specifying an appropriate compiler option. Warnings do not stop translation or linking. Warnings do not interfere with any output files.

The following are some representative warning messages:

```
declaration does not declare anything
```

```
pointless comparison of unsigned integer with zero
```

```
possible use of = where == was intended
```

Some warnings that start with `-W` can be disabled using the negative form of the option `-Wno-`. For example, option `-Wno-unknown-pragmas` disables option `-Wunknown-pragmas`.

Linux and macOS

Additional Warnings

The following Linux* and macOS options produce additional warnings:

Option	Result
`-W[no-]missing-prototypes`	Warn for missing prototypes.
`-W[no-]missing-declarations`	Warn for missing declarations.
`-W[no-]unused-variable`	Warn for unused variable.
`-W[no-]pointer-arith`	Warn for questionable pointer arithmetic.
`-W[no-]uninitialized`	Warn if a variable is used before being initialized.
`-W[no-]deprecated`	Display warnings related to deprecated features.
`-W[no-]abi`	Warn if generated code is not C++ ABI compliant.
`-W[no-]unused-function`	Warn if declared function is not used.
`-W[no-]unknown-pragmas`	Warn if an unknown `#pragma` directive is used.
`-W[no-]main`	Warn if return type of main is not expected.
`-W[no-]comment[s]`	Warn when /* appears in the middle of a /* */ comment.
`-W[no-]return-type`	Warn when a function uses the default `int` return type Warn when a return statement is used in a void function.

Errors

These messages report syntactic or semantic misuse of C or C++. The compiler always displays error messages. Errors suppress object code for the module containing the error and prevent linking, but they allow parsing to continue to detect other possible errors.

The following are some representative error messages:

```
missing closing quote
```

```
expression must have arithmetic type
```

```
expected a ";"
```

Remarks

Remark messages report common but sometimes unconventional use of C or C++. Remarks do not stop translation or linking. Remarks do not interfere with any output files.

The following are some representative remark messages:

```
function declared implicitly
```

```
type qualifiers are meaningless in this declaration
```

```
controlling expression is constant
```

Some remarks, warnings, and errors are numbered and can be disabled using option `-diag-disable=list` or `/Qdiag-disable:list`.

Example

Linux and macOS

```
-diag-disable=117,230,450
```

Windows

```
/Qdiag-disable:117,230,450
```

Option Summary

You can use the following compiler options to control remarks, warnings, and errors.

Linux and macOS

Option	Result
`-w`	Enables diagnostics for errors; disables diagnostics for warnings.
`-w1`	Enables diagnostics for warnings and errors.
`-w2`	Enables diagnostics for verbose warnings, warnings, and errors.
`-w3`	Enables diagnostics for remarks, warnings, and errors. Additional warnings are also enabled above level 2 warnings.
`-Wremarks`	Display remarks and comments.
`-Wbrief`	Display brief one-line diagnostics.
`-Wcheck`	Enable more strict diagnostics.
`-Werror-all`	Change all warnings and remarks to errors.
`-Werror`	Change all warnings to errors.

Windows

Option	Result
`/W0`	Enables diagnostics for errors; disables diagnostics for warnings.
`/W1`, `/W2`	Enables diagnostics for warnings and errors.
`/W3`	Enables diagnostics for remarks, warnings, and errors. Additional warnings are also enabled above level 2 warnings.
`/W4, /Wall`	Enables diagnostics for all level 3 warnings, plus informational warnings and remarks, which, in most cases, can be safely ignored.
`/W5`	Enables diagnostics for all remarks, warnings, and errors. This option produces the most diagnostic messages.
`/WL`	Display brief one-line diagnostics.
`/WX`	Change all warnings to errors.
`/Wp64`	Display diagnostics for 64-bit porting.

You can also control the display of diagnostic information with variations of the `[Q]diag` compiler option. This compiler option accepts numerous arguments and values, allowing you wide control over displayed diagnostic messages and reports.

Some of the most common variations include the following:

<table>
<tr><th>Option</th><th>Result</th></tr>
<tr><td>[Q]diag-enable<:|=>list</td><td>Enables a diagnostic message or a group of messages.</td></tr>
<tr><td>[Q]diag-disable<:|=>list</td><td>Disables a diagnostic message or a group of messages.</td></tr>
<tr><td>[Q]diag-warning<:|=>list</td><td>Tells the compiler to change diagnostics to warnings.</td></tr>
<tr><td>[Q]diag-error<:|=>list</td><td>Tells the compiler to change diagnostics to errors.</td></tr>
<tr><td>[Q]diag-remark<:|=>list</td><td>Tells the compiler to change diagnostics to remarks (comments).</td></tr>
</table>

The *list* items can be specific diagnostic IDs, one of the keywords `warn`, `remark`, or `error`, or a keyword specifying a certain group (`par`, `vec`, `driver`, `thread`, `port-linux` (available on Windows* systems), `port-win` (available on Linux* and macOS systems), or *`openmp`*). For more information, see `[Q]diag`.

Other diagnostic-related options include the following:

<table>
<tr><th>Option</th><th>Result</th></tr>
<tr><td>[Q]diag-dump</td><td>Tells the compiler to print all enabled diagnostic messages and stop compilation.</td></tr>
<tr><td>[Q]diag-file[<:|=>file]</td><td>Causes the results of diagnostic analysis to be output to a file.</td></tr>
<tr><td>[Q]diag-file-append[<:|=>file]</td><td>Causes the results of diagnostic analysis to be appended to a file.</td></tr>
<tr><td>[Q]diag-error-limit<:|=>n</td><td>Specifies the maximum number of errors allowed before compilation stops.</td></tr>
</table>

Part IV Compilation

This section contains information about features that can affect compilation, such as environment variables, and using configuration files.

Compilation Overview

Compilation Environment

You can customize the environment used during compilation using a combination of

- Configuration Files
- Environment variables
- Response Files

You can also modify the compilation by adding additional include directories for the compiler to search during compilation. See Specify Compiler Files for more information.

Default Compiler Behavior

The Intel® C++ Compiler Classic processes C/C++ language source files. Compilation can be divided into these major phases: :

- Preprocessing
- Semantic parsing
- Optimization
- Code generation
- Linking

By default, the compiler performs the first four phases of compilation and then invokes the linker to perform the linking phase. The default linkers are `ld` for Linux and `link` for Windows.

Default settings for the compiler include:

- Optimization level O2 (`-O2`)
- Floating point model = fast (`-fp-model=fast`)
- `icpc` C++ language standard: Gnu C++14 (`-std=gnu++14`)
- C++ runtime:
  - Linux: libstdc++, using headers and libraries installed on the system
  - Windows: Microsoft Visual C++ (MSVC) provided headers and libraries
- SVML and specific interfaces enabled to call into the Intel libirc library

Customize the Compilation Process

The Intel® C++ Compiler Classic provides multiple options to customize compilation.

Preprocessing

Several options are available to customize preprocessing. For example, you can:

- Specify the location of system and user header files
- Specify macros
- Stop the compilation process after preprocessing
- Send preprocessed output to stdout

You can optionally use your own preprocessor to generate a preprocessed file which can then be passed to the compiler.

For a detailed list of preprocessing options, see Preprocessor Options.

Compiling

Compiler options are not required to compile your program, but can be used to control different aspects of your application, such as:

- Code generation
- Optimization
- Output file (type, name, location)
- Linking properties
- Size of the executable
- Speed of the executable

For a detailed list of all compiler options, see Compiler Options.

Linking

You can perform the linking phase using the Intel compiler to invoke the linker (default) or by calling the linker directly.

> **NOTE** On Linux, calling the linker directly requires explicit understanding of which specific system and Intel libraries need to be linked in, as they will need to be passed directly to the linker.

To prevent default linking at compilation time, use the `-c` option. You must then explicitly pass along the generated object on the compilation command line and the compiler will create the final binary.

You can pass options to the linker for additional control of the linking phase. See Pass Options to the Linker for additional information.

Compiler Options
Specify Compiler Files
Preprocessor Options
Pass Options to the Linker

Supported Environment Variables

You can customize your system environment by specifying paths where the compiler searches for certain files such as libraries, include files, configuration files, and certain settings.

Compiler Compile-Time Environment Variables

The following table shows the compile-time environment variables that affect the compiler:

Compile-Time Environment Variable	Description
`CL` (Windows) `_CL_` (Windows)	Define the files and options you use most often with the CL variable. Note: You cannot set the CL environment variable to a string that contains an equal sign. You can use the pound sign instead. In the following example, the pound sign (#) is used as a substitute for an equal sign in the assigned string: `SET CL=/Dtest#100`
`COV_DIR` (Windows)	Same as `PROF_DIR`.
`COV_DPI` (Windows)	Same as `PROF_DPI`.
`IA32ROOT` (IA-32 architecture and Intel® 64 architecture)	Points to the directories containing the include and library files for a non-standard installation structure. **NOTE** IA-32 architecture is no longer supported on macOS*.
`ICCCFG`	Specifies the configuration file for customizing compilations when invoking the compiler using `icc`. Used instead of the default configuration file.
`ICPCCFG`	Specifies the configuration file for customizing compilations when invoking the compiler using `icpc`. Used instead of the default configuration file.
`ICLCFG` (Windows)	Specifies a configuration file, which the compiler should use instead of the default configuration file.
`INTEL_LICENSE_FILE`	Specifies the location for the Intel license file. **NOTE** On Windows, this environment variable cannot be set from Visual Studio.
`__INTEL_PRE_CFLAGS` `__INTEL_POST_CFLAGS`	Specifies a set of compiler options to add to the compile line. This is an extension to the facility already provided in the compiler configuration file `icl.cfg`. **NOTE** By default, a configuration file named `icl.cfg` (Windows), `icc.cfg` (Linux, macOS), or `icpc.cfg` (Linux, macOS) is used. This file is in the same directory as the compiler executable. To use another configuration file in another location, you can use the `ICLCFG` (Windows), `ICCCFG` (Linux, macOS), or `ICPCCFG` (Linux, macOS) environment variable to assign the directory and file name for the configuration file. You can insert command line options in the prefix position using `__INTEL_PRE_CFLAGS` or in the suffix position using `__INTEL_POST_CFLAGS`. The command line is built as follows:

Compile-Time Environment Variable	Description
	Syntax: (On Windows, use `icl`. On Linux or macOS, use `icc`) `icl/icc` *<PRE flags> <flags from configuration file> <flags from the compiler invocation> <POST flags>* **NOTE** The driver issues a warning that the compiler is overriding an option because of an environment variable, but only when you include the option `/W5` (Windows) or `-w3` (Linux and macOS).
`INTEL_TARGET_ARCH_IA32` (Linux and Windows)	Set this environment variable to target 32-bit compilations for all associated tools (this includes the compiler and Intel-specific linker tools). Without this environment variable, you will be required to use the explicit command line options, `/Qm32` on Windows and `-m32` on Linux, for each compiler invocation. **NOTE** IA-32 architecture is no longer supported on macOS. IA-32 is deprecated for other operating systems and will be removed in a future release.
`PATH`	Specifies the directories the system searches for binary executable files. **NOTE** On Windows, this also affects the search for Dynamic Link Libraries (DLLs).

`TMP`
`TMPDIR`
`TEMP`
	Specifies the location for temporary files. If none of these are specified, or writeable, or found, the compiler stores temporary files in `/tmp` (Linux, macOS) or the current directory (Windows).
	The compiler searches for these variables in the following order: `TMP`, `TMPDIR`, and `TEMP`.
	
	NOTE
	On Windows, these environment variables cannot be set from Visual Studio.

`LD_LIBRARY_PATH` (Linux)	Specifies the location for shared objects (.so files).
`DYLD_LIBRARY_PATH` (macOS)	Specifies the path for dynamic libraries.
`INCLUDE` (Windows)	Specifies the directories for the source header files (include files).
`LIB` (Windows)	Specifies the directories for all libraries used by the compiler and linker.
GNU Environment Variables and Extensions	
`CPATH` (Linux and macOS)	Specifies the path to include directory for C/C++ compilations.

Compile-Time Environment Variable	Description
C_INCLUDE_PATH (Linux and macOS)	Specifies path to include directory for C compilations.
CPLUS_INCLUDE_PATH (Linux and macOS)	Specifies path to include directory for C++ compilations.
DEPENDENCIES_OUTPUT (Linux and macOS)	Specifies how to output dependencies for make based on the non-system header files processed by the compiler. System header files are ignored in the dependency output.
GCC_EXEC_PREFIX (Linux)	Specifies alternative names for the linker (ld) and assembler (as).
GCCROOT (Linux)	Specifies the location of the GCC* binaries. Set this variable only when the compiler cannot locate the GCC binaries when using the -gcc-name option.
GXX_INCLUDE (Linux)	Specifies the location of the GCC headers. Set this variable to specify the locations of the GCC installed files when the compiler does not find the needed values as specified by the use of -gcc-name=*directory-name*/gcc or -gxx-name=*directory-name*/g++.
GXX_ROOT (Linux)	Specifies the location of the GCC binaries. Set this variable to specify the locations of the GCC installed files when the compiler does not find the needed values as specified by the use of -gcc-name=*directory-name*/gcc or -gxx-name=*directory-name*/g++.
LIBRARY_PATH (Linux and macOS)	Specifies the path for libraries to be used during the link phase.
SUNPRO_DEPENDENCIES (Linux)	This variable is the same as DEPENDENCIES_OUTPUT, except that system header files are not ignored.

NOTE INTEL_ROOT is an environment variable that is reserved for the Intel® Compiler. Its use is not supported.

Compiler Run-Time Environment Variables

The following table summarizes compiler environment variables that are recognized at run time.

Run-Time Environment Variable	Description
INTEL_CHKP_REPORT_MODE (Linux)	Changes the pointer checker reporting mode at run time. See Finding and Reporting Out-of-Bounds Errors.

Run-Time Environment Variable	Description
INTEL_ISA_DISABLE	Causes named features (in a comma-separated list) not to be visible on the host even if the CPUID reports that it has them onboard. See CPU Feature Targeting.
GNU extensions (recognized by the Intel OpenMP* compatibility library)	
GOMP_CPU_AFFINITY (Linux)	GNU extension recognized by the Intel OpenMP compatibility library. Specifies a list of OS processor IDs. You must set this environment variable before the first parallel region or before certain API calls including omp_get_max_threads(), omp_get_num_procs() and any affinity API calls. For detailed information on this environment variable, see *Thread Affinity Interface*. **Default:** Affinity is disabled
GOMP_STACKSIZE (Linux)	GNU extension recognized by the Intel OpenMP compatibility library. Same as OMP_STACKSIZE.KMP_STACKSIZE overrides GOMP_STACKSIZE, which overrides OMP_STACKSIZE. **Default:** See the description for OMP_STACKSIZE.
OpenMP Environment Variables (OMP_) and Extensions (KMP_)	
OMP_CANCELLATION	Activates cancellation of the innermost enclosing region of the type specified. If set to TRUE, the effects of the cancel construct and of cancellation points are enabled and cancellation is activated. If set to FALSE, cancellation is disabled and the cancel construct and cancellation points are effectively ignored. **NOTE** Internal barrier code will work differently depending on whether the cancellation is enabled. Barrier code should repeatedly check the global flag to figure out if the cancellation had been triggered. If a thread observes the cancellation it should leave the barrier prematurely with the return value 1 (may wake up other threads). Otherwise, it should leave the barrier with the return value 0. Enables (TRUE) or disables (FALSE) cancellation of the innermost enclosing region of the type specified. **Default:** FALSE **Example:** OMP_CANCELLATION=TRUE

Run-Time Environment Variable	Description
`OMP_DISPLAY_ENV`	Enables (`TRUE`) or disables (`FALSE`) the printing to stderr of the OpenMP version number and the values associated with the OpenMP environment variable. Possible values are: TRUE, FALSE, or VERBOSE. **Default:** FALSE **Example:** `OMP_DISPLAY_ENV=TRUE`
`OMP_DEFAULT_DEVICE`	Sets the device that will be used in a target region. The OpenMP routine `omp_set_default_device` or a `device` clause in a target pragma can override this variable. If no device with the specified device number exists, the code is executed on the host. If this environment variable is not set, device number 0 is used.
`OMP_DYNAMIC`	Enables (`TRUE`) or disables (`FALSE`) the dynamic adjustment of the number of threads. **Default:** FALSE **Example:** `OMP_DYNAMIC=TRUE`
`OMP_MAX_ACTIVE_LEVELS`	The maximum number of levels of parallel nesting for the program. Possible values: Non-negative integer. **Default:** 1
`OMP_NESTED`	Deprecated; use `OMP_MAX_ACTIVE_LEVELS` instead.
`OMP_NUM_THREADS`	Sets the maximum number of threads to use for OpenMP parallel regions if no other value is specified in the application. The value can be a single integer, in which case it specifies the number of threads for all parallel regions. The value can also be a comma-separated list of integers, in which case each integer specifies the number of threads for a parallel region at a nesting level. The first position in the list represents the outer-most parallel nesting level, the second position represents the next-inner parallel nesting level, and so on. At any level, the integer can be left out of the list. If the first integer in a list is left out, it implies the normal default value for threads is used at the outer-most level. If the integer is left out of any other level, the number of threads for that level is inherited from the previous level.

Run-Time Environment Variable	Description
	This environment variable applies to the options `Qopenmp` (Windows) or `qopenmp` (Linux and macOS), and `Qparallel` (Windows) or `parallel` (Linux and macOS). **Default:** The number of processors visible to the operating system on which the program is executed. **Syntax:** `OMP_NUM_THREADS=value[,value]*`

`OMP_PLACES`	Specifies an explicit ordered list of places, either as an abstract name describing a set of places or as an explicit list of places described by nonnegative numbers. An exclusion operator "!" can also be used to exclude the number or place immediately following the operator.
	
	For **explicit lists**, the meaning of the numbers and how the numbering is done for a list of nonnegative numbers are implementation defined. Generally, the numbers represent the smallest unit of execution exposed by the execution environment, typically a hardware thread.
	
	Intervals can be specified using the `<lower-bound>` : `<length>` : `<stride>` notation to represent the following list of numbers:
	
	`"<lower-bound>, <lower-bound> + <stride>, ..., <lower-bound> +(<length>-1)*<stride>."`
	
	When `<stride>` is omitted, a unit stride is assumed. Intervals can specify numbers within a place as well as sequences of places.
	
	`# EXPLICIT LIST EXAMPLE`
	`setenv OMP_PLACES "{0,1,2,3},{4,5,6,7},{8,9,10,11},{12,13,14,15}"`
	`setenv OMP_PLACES "{0:4},{4:4},{8:4},{12:4}"`
	`setenv OMP_PLACES "{0:4}:4:4"`
	
	The **abstract names** listed below should be understood by the execution and run-time environment:
	
	• `threads`: Each place corresponds to a single hardware thread on the target machine.
	• `cores`: Each place corresponds to a single core (having one or more hardware threads) on the target machine.
	• `ll_caches`: Each place corresponds to a set of cores that share the last level cache on the device.

<table>
<tr><th>Run-Time Environment Variable</th><th>Description</th></tr>
<tr><td></td><td>

<code>numa_domains</code>: Each place corresponds to a set of cores for which their closest memory on the device is 1) the same memory and 2) at a similar distance from the cores.
<code>sockets</code>: Each place corresponds to a single socket (consisting of one or more cores) on the target machine.

When requesting fewer places or more resources than available on the system, the determination of which resources of type <code>abstract_name</code> are to be included in the place list is implementation-defined. The precise definitions of the abstract names are implementation defined. An implementation may also add abstract names as appropriate for the target platform. The abstract name may be appended by a positive number in parentheses to denote the length of the place list to be created, that is <code>abstract_name(num-places)</code>.
<pre><code># ABSTRACT NAMES EXAMPLE
  setenv OMP_PLACES threads
  setenv OMP_PLACES threads(4)</code></pre>
NOTE
If any numerical values cannot be mapped to a processor on the target platform the behavior is implementation-defined. The behavior is also implementation-defined when the <code>OMP_PLACES</code> environment variable is defined using an abstract name.
</td></tr>
<tr><td><code>OMP_PROC_BIND</code> (Windows, Linux)</td><td>
Sets the thread affinity policy to be used for parallel regions at the corresponding nested level. Enables (<code>TRUE</code>) or disables (<code>FALSE</code>) the binding of threads to processor contexts. If enabled, this is the same as specifying <code>KMP_AFFINITY=scatter</code>. If disabled, this is the same as specifying <code>KMP_AFFINITY=none</code>.
Acceptable values: <code>TRUE</code>, <code>FALSE</code>, or a comma separated list, each element of which is one of the following values: <code>PRIMARY</code>, <code>MASTER</code> (deprecated), <code>CLOSE</code>, <code>SPREAD</code>.
Default: <code>FALSE</code>
If set to <code>FALSE</code>, the execution environment may move OpenMP threads between OpenMP places, thread affinity is disabled, and proc_bind clauses on parallel constructs are ignored. Otherwise, the execution environment should not move OpenMP
</td></tr>
</table>

Run-Time Environment Variable	Description
	threads between OpenMP places, thread affinity is enabled, and the initial thread is bound to the first place in the OpenMP place list. If set to PRIMARY, all threads are bound to the same place as the primary thread. If set to CLOSE, threads are bound to successive places, close to where the primary thread is bound. If set to SPREAD, the primary thread's partition is subdivided and threads are bound to single place successive sub-partitions. **NOTE** KMP_AFFINITY takes precedence over GOMP_CPU_AFFINITY and OMP_PROC_BIND. GOMP_CPU_AFFINITY takes precedence over OMP_PROC_BIND.
OMP_SCHEDULE	Sets the run-time schedule type and an optional chunk size. **Default:** static, no chunk size specified **Example syntax:** OMP_SCHEDULE="[modifier:]kind[,chunk_size]" where • modifier is one of monotonic or nonmonotonic • kind is one of static, dynamic, guided, or auto • chunk_size is a positive integer **NOTE** Some environment variables are available for both Intel® microprocessors and non-Intel microprocessors, but may perform additional optimizations for Intel® microprocessors than for non-Intel microprocessors.
OMP_STACKSIZE	Sets the number of bytes to allocate for each OpenMP thread to use as the private stack for the thread. Recommended size is 16M. Use the optional suffixes to specify byte units: B (bytes), K (Kilobytes), M (Megabytes), G (Gigabytes), or T (Terabytes) to specify the units. If you specify a value without a suffix, the byte unit is assumed to be K (Kilobytes).

Run-Time Environment Variable	Description
	This variable does not affect the native operating system threads created by the user program, or the thread executing the sequential part of an OpenMP program or parallel programs created using the option `Qparallel` (Windows) or `parallel` (Linux and macOS) . The `kmp_{set,get}_stacksize_s()` routines set/retrieve the value. The `kmp_set_stacksize_s()` routine must be called from sequential part, before first parallel region is created. Otherwise, calling `kmp_set_stacksize_s()` has no effect. **Default (IA-32 architecture):** 2M **Default (Intel® 64 architecture):** 4M **NOTE** IA-32 architecture is no longer supported on macOS. IA-32 is deprecated for other operating systems and will be removed in a future release. **Related environment variables:** `KMP_STACKSIZE` (overrides `OMP_STACKSIZE`). **Syntax:** `OMP_STACKSIZE=value`
`OMP_THREAD_LIMIT`	Limits the number of simultaneously-executing threads in an OpenMP program. If this limit is reached and another native operating system thread encounters OpenMP API calls or constructs, the program can abort with an error message. If this limit is reached when an OpenMP parallel region begins, a one-time warning message might be generated indicating that the number of threads in the team was reduced, but the program will continue. This environment variable is only used for programs compiled with the following options: `Qopenmp` (Windows) or `qopenmp` (Linux and macOS), or `Qparallel` (Windows) or `parallel` (Linux and macOS) . The `omp_get_thread_limit()` routine returns the value of the limit. **Default:** No enforced limit **Related environment variable:** `KMP_ALL_THREADS` (overrides `OMP_THREAD_LIMIT`). **Example syntax:** `OMP_THREAD_LIMIT=value`
`OMP_WAIT_POLICY`	Decides whether threads spin (active) or yield (passive) while they are waiting.

Run-Time Environment Variable	Description
	OMP_WAIT_POLICY=ACTIVE is an alias for KMP_LIBRARY=turnaround, and OMP_WAIT_POLICY=PASSIVE is an alias for KMP_LIBRARY=throughput. **Default:** Passive **Syntax:** OMP_WAIT_POLICY=value
OMP_DISPLAY_AFFINITY	Instructs the runtime to display formatted affinity information for all OpenMP threads in the parallel region upon entering the first parallel region and when any change occurs in the information accessible by the format specifiers listed in the OMP_AFFINITY_FORMAT entry. Possible values: TRUE or FALSE **Default:** FALSE
OMP_AFFINITY_FORMAT	Defines the format when displaying OpenMP thread affinity information. Possible values are any string with the following format field available: • %t or %{team_num}: Value returned by omp_get_team_num() • %T or %{num_teams}: Value returned by omp_get_num_teams() • %L or %{nesting_level}: Value returned by omp_get_level() • %n or %{thread_num}: Value returned by omp_get_thread_num() • %a or %{ancestor_tnum}: Value returned by omp_get_ancestor_thread_num(omp_get_level() - 1) • %H or %{host}: Name of host device • %P or %{process_id}: Process ID • %i or %{native_thread_id}: Native thread ID on the platform • %A or %{thread_affinity}: List of processor ID on which a thread may execute **Default:** 'OMP: pid %P tid %i thread %n bound to OS proc set {%A}'
OMP_MAX_TASK_PRIORITY	Controls the use of task priorities by setting the initial value. Possible values: Non-negative integer. **Default:** 0
OMP_TOOL	Controls whether the OpenMP runtime will try to register a first party tool that uses OMPT interface. Possible values: ENABLED or DISABLED.

Run-Time Environment Variable	Description
	Default: ENABLED **NOTE** Only the host OpenMP runtime is supported.
OMP_TOOL_LIBRARIES	Sets a list of first-party tool locations that use the OMPT interface. The list enumerates names of dynamically-loadable libraries with OS-specific path separator. **Default:** Empty **NOTE** Only the host OpenMP runtime is supported.
OMP_TOOL_VERBOSE_INIT	Controls whether the OpenMP runtime will verbosely log the registration of a tool that uses the OMPT interface. Possible values: • DISABLED: Do not log the registration. • STDOUT: Log the registration to stdout. • STDERR: Log the registration to stderr. • File_Name: Log the registration to the location specified by File_Name. **Default:**DISABLED **NOTE** Only the host OpenMP runtime is supported.
OMP_DEBUG	Controls whether the OpenMP runtime collects information that an OMPD library may need to support a tool. Possible values: ENABLED or DISABLED. **Default:** DISABLED **NOTE** Only the host OpenMP runtime is supported.
OMP_ALLOCATOR	Specifies the default allocator for allocation calls, directives, and clauses that do not specify an allocator. **Default:** omp_default_mem_alloc **Syntax:** <PredefinedMemAllocator> | <PredefinedMemSpace> | <PredefinedMemSpace>:<Traits>

Run-Time Environment Variable	Description
	Currently supported values for <PredefinedMemAllocator> and <PredefinedMemSpace> : • `omp_default_mem_alloc` and `omp_default_mem_space` Additional values are supported if `libmemkind` is available and there is system support for it: • `omp_high_bw_mem_alloc` and `omp_high_bw_mem_space` • `omp_large_cap_mem_alloc` and `omp_large_cap_mem_space` Refer to the OpenMP specification for more information.
`OMP_NUM_TEAMS`	Sets the maximum number of teams created by a teams construct by setting nteams-var ICV. Possible values: Positive integer. **Default:** 1
`OMP_TEAMS_THREAD_LIMIT`	Sets the maximum number of OpenMP threads to use in each team created by a teams construct. Possible values: Positive integer. **Default:** <NumberOfProcessors> / <nteams-var ICV>
`KMP_AFFINITY` (Linux, Windows)	Enables run-time library to bind threads to physical processing units. You must set this environment variable before the first parallel region, or certain API calls including `omp_get_max_threads()`, `omp_get_num_procs()` and any affinity API calls. For detailed information on this environment variable, see *Thread Affinity Interface*. **Default:** noverbose,warnings,noreset,respect,granularity=core,none Default (Windows with multiple processor groups): noverbose,warnings,noreset,norespect,granularity=group,compact,0,0 **NOTE** On Windows with multiple processor groups, the norespect affinity modifier is assumed when the process affinity mask equals a single processor group (which is default on Windows). Otherwise, the respect affinity modifier is used.

Run-Time Environment Variable	Description
KMP_ALL_THREADS	Limits the number of simultaneously-executing threads in an OpenMP program. If this limit is reached and another native operating system thread encounters OpenMP API calls or constructs, then the program may abort with an error message. If this limit is reached at the time an OpenMP parallel region begins, a one-time warning message may be generated indicating that the number of threads in the team was reduced, but the program will continue execution. This environment variable is only used for programs compiled with the `Qopenmp`(Windows) or `qopenmp` (Linux and macOS) option. **Default:** No enforced limit.
KMP_BLOCKTIME	Sets the time, in milliseconds, that a thread should wait, after completing the execution of a parallel region, before sleeping. Use the optional character suffixes: `s` (seconds), `m` (minutes), `h` (hours), or `d` (days) to specify the units. Specify `infinite` for an unlimited wait time. **Default:** 200 milliseconds **Related Environment Variable:** `KMP_LIBRARY` environment variable.
KMP_CPUINFO_FILE	Specifies an alternate file name for a file containing the machine topology description. The file must be in the same format as `/proc/cpuinfo`. **Default:** None
KMP_DETERMINISTIC_REDUCTION	Enables (`TRUE`) or disables (`FALSE`) the use of a specific ordering of the reduction operations for implementing the reduction clause for an OpenMP parallel region. This has the effect that, for a given number of threads, in a given parallel region, for a given data set and reduction operation, a floating point reduction done for an OpenMP reduction clause has a consistent floating point result from run to run, since round-off errors are identical. **NOTE** When compiling, you must set the following flag to ensure correct behavior: • `-fp-model precise` (Linux) • `-fp:precise` (Windows) **Default:** `FALSE`

Run-Time Environment Variable	Description
`KMP_DYNAMIC_MODE`	Selects the method used to determine the number of threads to use for a parallel region when `OMP_DYNAMIC=TRUE`. Possible values: (`asat` | `load_balance` | `thread_limit`), where, • `asat`: estimates number of threads based on parallel start time; **NOTE** Support for `asat` (automatic self-allocating threads) is now deprecated and will be removed in a future release. • `load_balance`: tries to avoid using more threads than available execution units on the machine; • `thread_limit`: tries to avoid using more threads than total execution units on the machine. **Default (IA-32 architecture):** `load_balance` (on all supported OSes) **Default (Intel® 64 architecture):** `load_balance` (on all supported OSes) **NOTE** IA-32 architecture is no longer supported on macOS. IA-32 is deprecated for other operating systems and will be removed in a future release.
`KMP_HOT_TEAMS_MAX_LEVEL`	Sets the maximum nested level to which teams of threads will be hot. **NOTE** A *hot* team is a team of threads optimized for faster reuse by subsequent parallel regions. In a hot team, threads are kept ready for execution of the next parallel region, in contrast to the cold team, which is freed after each parallel region, with its threads going into a common pool of threads. For values of 2 and above, nested parallelism should be enabled. **Default:** 1
`KMP_HOT_TEAMS_MODE`	Specifies the run-time behavior when the number of threads in a hot team is reduced. Possible values:

Run-Time Environment Variable	Description
	• 0: Extra threads are freed and put into a common pool of threads. • 1: Extra threads are kept in the team in reserve, for faster reuse in subsequent parallel regions. **Default:** 0
`KMP_HW_SUBSET`	Specifies the subset of available hardware resources for the hardware topology hierarchy. The subset is specified in terms of number of units per upper layer unit starting from top layer downwards. For example, it can specify the number of sockets (top layer units), cores per socket, and the threads per core, to use with an OpenMP application. It is a convenient alternative to writing complicated explicit affinity settings or a limiting process affinity mask. You can also specify an offset value to set which resources to use. When available, you can specify attributes to select different subsets of resources. An extended syntax is available when `KMP_TOPOLOGY_METHOD=hwloc`. Depending on what resources are detected, you may be able to specify additional resources, such as NUMA nodes and groups of hardware resources that share certain cache levels. **Basic syntax:** `[num_units]ID[@`*`offset`*`][:`*`attribute`*`] [, [num_units]ID[@`*`offset`*`][:`*`attribute`*`]...]` where • `num_units` is either a positive integer, which requests an exact number of resources, or an asterisk (*), which means using all available resources at that layer (for example, using all cores per socket). If `num_units` is not specified, the asterisk (*) semantics are assumed. • `ID` is a supported ID: *`S - socket`* — *num_units* specifies the requested number of sockets. *`D - die`* — *num_units* specifies the requested number of dies per socket. *`C - core`* — *num_units* specifies the requested number of cores per die - if any - otherwise, per socket. *`T - thread`* — *num_units* specifies the requested number of HW threads per core.

Run-Time Environment Variable	Description
	Supported unit IDs are not case-sensitive. • `offset` is the number of units to skip (optional). • `attribute` is an attribute differentiating resources at a particular layer (optional). This is only available for the core layer on machines with Intel® Hybrid Technology. The attributes available to users are: • Core type: Either *intel_atom* or *intel_core* • Core efficiency: Specified as `effnum` where *num* is a number from 0 to the number of core efficiencies detected in the machine topology minus one. For example: `eff0`. The greater the efficiency number, the more performant the core. There may be more core efficiencies than core types, which can be viewed by setting `KMP_AFFINITY=verbose`. **NOTE** The hardware cache can be specified as a unit, for example L2 for L2 cache, or LL for last level cache. **Extended syntax when `KMP_TOPOLOGY_METHOD=hwloc`:** Additional IDs can be specified if detected. For example: *`N - numa`*: *num_units* specifies the requested number of NUMA nodes per upper layer unit, e.g. per socket. *`TI - tile`*: *num_units* specifies the requested number of tiles to use per upper layer unit, e.g. per NUMA node. When any *numa* or *tile* units are specified in `KMP_HW_SUBSET`, the `KMP_TOPOLOGY_METHOD` will be automatically set to `hwloc`,so there is no need to set it explicitly. If you don't specify one or more types of resource, such as socket or thread, all available resources of that type are used. The run-time library prints a warning, and the setting of `KMP_HW_SUBSET` is ignored if: • a resource is specified, but detection of that resource is not supported by the chosen topology detection method and/or • a resource is specified twice. An exception to this condition is if attributes differentiate the resource.

Run-Time Environment Variable	Description
	• attributes are used when unavailable, not detected in the machine topology, or conflict with each other. This variable does not work if the OpenMP affinity is set to `disabled`. **Default:** If omitted, the default value is to use all the available hardware resources. **Examples:** • `2s,4c,2t`: Use the first 2 sockets (s0 and s1), the first 4 cores on each socket (c0 - c3), and 2 threads per core. • `2s@2,4c@8,2t`: Skip the first 2 sockets (s0 and s1) and use 2 sockets (s2-s3), skip the first 8 cores (c0-c7) and use 4 cores on each socket (c8-c11), and use 2 threads per core. • `5C@1,3T`: Use all available sockets, skip the first core and use 5 cores, and use 3 threads per core. • `1T`: Use all cores on all sockets, 1 thread per core. • `1s, 1d, 1n, 1c, 1t`: Use 1 socket, 1 die, 1 NUMA node, 1 core, 1 thread - use HW thread as a result. • `4c:intel_atom,5c:intel_core`: Use all available sockets and use 4 Intel Atom® processor cores and 5 Intel® Core™ processor cores per socket. • `2c:eff0,3c:eff1`: Use all available sockets and use 2 cores with efficiency 0 and 3 cores with efficiency 1 per socket. • `1s, 1c, 1t`: Use 1 socket, 1 core, 1 thread. This may result in using single thread on a 3-layer topology architecture, or multiple threads on 4-layer or 5-layer architecture. Result may even be different on the same architecture, depending on `KMP_TOPOLOGY_METHOD` specified, as hwloc can often detect more topology layers than default method used by the OpenMP run-time library. To see the result of the setting, you can specify the `verbose` modifier in for the `KMP_AFFINITY` environment variable. The OpenMP run-time library will output to stderr stream the information about discovered HW topology before and after the `KMP_HW_SUBSET` setting was applied. For example, on Intel® Xeon Phi™ 7210 CPU in SNC-4 Clustering Mode, the setting `KMP_AFFINITY=verbose KMP_HW_SUBSET=1N,1L2,1L1,1T` outputs various

Run-Time Environment Variable	Description
	verbose information to stderr, including the following lines about discovered HW topology before and after KMP_HW_SUBSET was applied: • Info #191: KMP_AFFINITY: 1 socket x 4 NUMA domains/socket x 8 tiles/NUMA domain x 2 cores/tile x 4 threads/core. (64 total cores) • Info #191: KMP_HW_SUBSET 1 socket x 1 NUMA domain/socket x 1 tile/NUMA domain x 1 core/tile x 1 thread/core (1 total cores)
KMP_INHERIT_FP_CONTROL	Enables (TRUE) or disables (FALSE) the copying of the floating-point control settings of the primary thread to the floating-point control settings of the OpenMP worker threads at the start of each parallel region. **Default:** TRUE
KMP_LIBRARY	Selects the OpenMP run-time library execution mode. The values for this variable are serial, turnaround, or throughput. **Default:** throughput
KMP_PLACE_THREADS	Deprecated; use KMP_HW_SUBSET instead.
KMP_SETTINGS	Enables (TRUE) or disables (FALSE) the printing of OpenMP run-time library environment variables during program execution. Two lists of variables are printed: user-defined environment variables settings and effective values of variables used by OpenMP run-time library. **Default:** FALSE
KMP_STACKSIZE	Sets the number of bytes to allocate for each OpenMP thread to use as its private stack. Recommended size is 16m. Use the optional suffixes to specify byte units: B (bytes), K (Kilobytes), M (Megabytes), G (Gigabytes), or T (Terabytes) to specify the units. If you specify a value without a suffix, the byte unit is assumed to be K (Kilobytes). This variable does not affect the native operating system threads created by the user program nor the thread executing the sequential part of an OpenMP program or parallel programs created using the option Qparallel (Windows) or parallel (Linux and macOS) . KMP_STACKSIZE overrides GOMP_STACKSIZE, which overrides OMP_STACKSIZE. **Default (IA-32 architecture):** 2m

<table>
<tr><th>Run-Time Environment Variable</th><th>Description</th></tr>
<tr><td></td><td>Default (Intel® 64 architecture): 4m

NOTE IA-32 architecture is no longer supported on macOS. IA-32 is deprecated for other operating systems and will be removed in a future release.</td></tr>
<tr><td><code>KMP_TOPOLOGY_METHOD</code></td><td>Forces OpenMP to use a particular machine topology modeling method.

Possible values are:
<code>all</code>: Lets OpenMP choose which topology method is most appropriate based on the platform and possibly other environment variable settings.
<code>cpuid_leaf11</code>: Decodes the APIC identifiers as specified by leaf 11 of the cpuid instruction.
<code>cpuid_leaf4</code>: Decodes the APIC identifiers as specified in leaf 4 of the cpuid instruction.
<code>cpuinfo</code>: If <code>KMP_CPUINFO_FILE</code> is not specified, forces OpenMP to parse <code>/proc/cpuinfo</code> to determine the topology (Linux only). If <code>KMP_CPUINFO_FILE</code> is specified as described above, uses it (Windows or Linux).
<code>group</code>: Models the machine as a 2-level map, with level 0 specifying the different processors in a group, and level 1 specifying the different groups (Windows 64-bit only) .
NOTE
Support for <code>group</code> is now deprecated and will be removed in a future release. Use <code>all</code> instead.
<code>flat</code>: Models the machine as a flat (linear) list of processors.
<code>hwloc</code>: Models the machine as the Portable Hardware Locality* (hwloc) library does. This model is the most detailed and includes, but is not limited to: numa nodes, packages, cores, hardware threads, caches, and Windows processor groups.
Default: <code>all</code></td></tr>
<tr><td><code>KMP_USER_LEVEL_MWAIT</code></td><td>Enables (<code>TRUE</code>) or disables (<code>FALSE</code>) the use of user-level mwait as alternative to putting waiting threads to sleep, if available, either from ring3 or <code>WAITPKG</code>.

Default: <code>FALSE</code></td></tr>
</table>

Run-Time Environment Variable	Description
`KMP_VERSION`	Enables (`TRUE`) or disables (`FALSE`) the printing of OpenMP run-time library version information during program execution. **Default:** `FALSE`
`KMP_WARNINGS`	Enables (`TRUE`) or disables (`FALSE`) displaying warnings from the OpenMP run-time library during program execution. **Default:** `TRUE`
Profile Guided Optimization (PGO_) Environment Variables	
`INTEL_PROF_DUMP_CUMULATIVE`	When using interval profile dumping (initiated by `INTEL_PROF_DUMP_INTERVAL` or the function `_PGOPTI_Set_Interval_Prof_Dump`) during the execution of an instrumented user application, allows creation of a single `.dyn` file to contain profiling information instead of multiple `.dyn` files. If not set, executing an instrumented user application creates a new `.dyn` file for each interval. Setting this environment variable is useful for applications that do not terminate or those that terminate abnormally (bypass the normal exit code).
`INTEL_PROF_DUMP_INTERVAL`	Initiates interval profile dumping in an instrumented user application. This environment variable may be used to initiate Interval Profile Dumping in an instrumented application. See Interval Profile Dumping for more information
`INTEL_PROF_DYN_PREFIX`	Specifies the prefix to be used for the `.dyn` filename to distinguish it from the other `.dyn` files dumped by other PGO runs. Executing the instrumented application generates a .dyn filename as follows: <prefix>_<timestamp>_<pid>.dyn, where <prefix> is the identifier that you have specified. **NOTE** The value specified in this environment variable must not contain < > : " / \ | ? * characters. The default naming scheme is used if an invalid prefix is specified.
`PROF_DIR`	Specifies the directory where profiling files (files with extensions `.dyn`, `.dpi`, `.spi` and so on) are stored. The default is to store the `.dyn` files in the

Run-Time Environment Variable	Description
	source directory of the file containing the first executed instrumented routine in the binary compiled with [Q]prof-gen option. This variable applies to all three phases of the profiling process: • Instrumentation compilation and linking • Instrumented execution • Feedback compilation
PROF_DPI	Name for the .dpi file. **Default:** pgopti.dpi
PROF_DUMP_INTERVAL	Deprecated; use INTEL_PROF_DUMP_INTERVAL instead.
PROF_NO_CLOBBER	Alters the feedback compilation phase slightly. By default, during the feedback compilation phase, the compiler merges data from all dynamic information files and creates a new pgopti.dpi file if the .dyn files are newer than an existing pgopti.dpi file. When this variable is set, the compiler does not overwrite the existing pgopti.dpi file. Instead, the compiler issues a warning. You must remove the pgopti.dpi file if you want to use additional dynamic information files.

The following table summarizes CPU environment variables that are recognized at run time.

Runtime configuration	Default value	Description
CL_CONFIG_CPU_FORCE_PRIVATE_MEM_SIZE	32KB	Forces CL_DEVICE_PRIVATE_MEM_SIZE for the CPU device to be the given value. The value must include the unit; for example: 8MB, 8192KB, 8388608B. **NOTE** You must compile your host application with sufficient stack size.
CL_CONFIG_CPU_FORCE_LOCAL_MEM_SIZE	32KB	Forces CL_DEVICE_LOCAL_MEM_SIZE for CPU device to be the given value. The value needs to be set with size including units, examples: 8MB, 8192KB, 8388608B.

Runtime configuration	Default value	Description
		NOTE You must compile your host application with sufficient stack size. Our recommendation is to set the stack size equal to twice the local memory size to cover possible application and OpenCL Runtime overheads.
`CL_CONFIG_CPU_EXPENSIVE_MEM_OPT`	0	A bitmap indicating enabled expensive memory optimizations. These optimizations may lead to more JIT compilation time, but give some performance benefit. **NOTE** Currently, only the least significant bit is available. Available bits: • 0: OpenCL address space alias analysis
`CL_CONFIG_CPU_STREAMING_ALWAYS`	False	Controls whether non-temporal instructions are used.

Thread Affinity Interface

Pass Options to the Linker

Specify Linker Options

This topic describes the options that let you control and customize linking with tools and libraries and define the output of the linker.

Linux and macOS

This section describes options specified at compile-time that take effect at link-time to define the output of the `ld` linker. See the `ld` man page for more information on the linker.

Option	Description
`-L`*directory*	Instruct the linker to search *directory* for libraries.

Option	Description
`-Qoption,`*tool,list*	Passes an argument list to another program in the compilation sequence, such as the assembler or linker.
`-shared`	Instructs the compiler to build a Dynamic Shared Object (DSO) instead of an executable.
`-shared-libgcc`	`-shared-libgcc` has the opposite effect of `-static-libgcc` . When it is used, the GNU standard libraries are linked in dynamically, allowing the user to override the static linking behavior when the `-static` option is used. **NOTE** Note: By default, all C++ standard and support libraries are linked dynamically.
`-shared-intel`	Specifies that all Intel-provided libraries should be linked dynamically.
`-static`	Causes the executable to link all libraries statically, as opposed to dynamically. When `-static` is not used: • `/lib/ld-linux.so.2` is linked in • all other libs are linked dynamically When `-static` is used: • `/lib/ld-linux.so.2` is not linked in • all other libs are linked statically
`-static-libgcc`	This option causes the GNU standard libraries to be linked in statically.
`-Bstatic` `-Bdynamic`	Either option is placed in the linker command line corresponding to its location on the user command line to control the linking behavior of any library being passed in via the command line.
`-static-intel`	This option causes Intel-provided libraries to be linked in statically. It is the opposite of `-shared-intel`.
`-Wl,`*optlist*	This option passes a comma-separated list (*optlist*) of options to the linker.
`-Xlinker` *val*	This option passes a value (*val*), such as a linker option, an object, or a library, directly to the linker.

Windows

This section describes options specified at compile-time that take effect at link-time.

You can use the `link` option to pass options specifically to the linker at compile time. For example:

```
icl a.cpp libfoo.lib /link -delayload:comct132.dll
```

In this example, the compiler recognizes that `libfoo.lib` is a library that should be linked with `a.cpp`, so it does not need to follow the `link` option on the command line. The compiler does not recognize `-delayload:comct132.dll`, so the `link` option is used to direct the option to the linking phase. On C++, you can use the `Qoption` option to pass options to various tools, including the linker. You can also use `#pragma comment` on C++ to pass options to the linker. For example:

```
#pragma comment(linker, "/defaultlib:mylib.lib")
```

OR

```
#pragma comment(lib, "mylib.lib")
```

Both examples instruct the compiler to link `mylib.lib` at link time.

Linking Tools and Options

This topic describes how to use the Intel® linking tools, `xild` (Linux* and macOS) and `xilink` (Windows*).

The Intel® linking tools behave differently on different platforms. The following sections summarize the primary differences between linking behavior.

Linux* and macOS Linking Behavior Summary

The linking tool invokes the Intel® C++ Compiler to perform IPO if objects containing `IR` (intermediate representation) are found. These are mock objects. The tool invokes GNU `ld` to link the application.

The command-line syntax for `xild` is the same as that of the GNU linker:

```
xild [<options>] <normal command-line>
```

where:

- `[<options>]`: One or more options supported only by `xild` (optional).
- `<normal command-line>`: Linker command line containing a set of valid arguments for `ld`.

To create the file `app` using IPO, use the option `o`*[filename]* as shown in the following example:

```
xild -qipo-fas-oapp a.o b.o c.o
```

The linking tool calls the compiler to perform IPO for objects containing IR and creates a new list of object(s) to be linked. The linker then calls `ld` to link the object files that are specified in the new list and produce the application with the name specified by the `o` option. The linker supports the `ipo`[*n*] option and `ipo-separate` option.

To display a list of the supported link options from `xild`, use the following command:

```
$ xild -qhelp
```

Windows* Linking Behavior Summary

The linking tool invokes the Intel® C++ Compiler to perform multi-file IPO if objects containing `IR` (intermediate representation) is found. These are mock objects. It invokes the Microsoft linker `link.exe` to link the application.

The command-line syntax for the Intel® linker is the same as that of the Microsoft linker:

```
xilink [<options>] <normal command-line>
```

where:

Windows* Linking Behavior Summary

• `[<options>]`: One or more options supported only by `xilink` (optional).
• `<normal command-line>`: Linker command line containing a set of valid arguments for the Microsoft linker.
 	
To place the multifile IPO executable in `ipo_file.exe`, use the linker option `out`:*[filename]* , for example:
 	
`xilink -qipo-fas/out:ipo_file.exe a.obj b.obj c.obj`
 	
The linker calls the compiler to perform IPO for objects containing `IR` and creates a new list of object(s) to be linked. The linker calls Microsoft `link.exe` to link the object files that are specified in the new list and produce the application with the name specified by the `out`:*[filename]* linker option.
 	
To display a list of support link options from `xilink` , use the following command:
 	
`>> xilink /qhelp`
 	
`xilink.exe` accepts all the options of `link.exe` and will pass them on to `link.exe` at the final linking stage.

Using the Linking Tools

You must use the Intel® linking tools to link your application if the following conditions apply:

- Your source files were compiled with multi-file IPO enabled. Multi-file IPO is enabled by specifying compiler option `[Q]ipo`.
- You would normally invoke the GNU linker (`ld`) to link your application.
- You would normally invoke the Microsoft linker (`link.exe`) to link your application.

Linker Options

The following table provides information on linking options.

Linking Tools Option	Description
`qdiag-`[*type*]=[*diag-list*]	Controls the display of diagnostic information. The *type* is an action to perform on diagnostics. Possible values are: • **Enable:** Enables a diagnostic message or a group of messages. • **Disable:** Disables a diagnostic message or a group of messages. The *diag-list* is a diagnostic group or ID value. Possible values are: • **thread:** Specifies diagnostic messages that help in thread-enabling a program. • **vec:** Specifies diagnostic messages issued by the vectorizer. • **par:** Specifies diagnostic messages issued by the auto-parallelizer (parallel optimizer). • **openmp:** Specifies diagnostic messages issued by the OpenMP* parallelizer. • **warn:** Specifies diagnostic messages that have a "warning" severity level. • **error:** Specifies diagnostic messages that have an "error" severity level. • **remark:** Specifies diagnostic messages that are remarks or comments. • **cpu-dispatch:** Specifies the CPU dispatch remarks for diagnostic messages. These remarks are enabled by default. • **id[,id,...]:** Specifies the ID number of one or more messages. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each "id".

Linking Tools Option	Description
	• **tag[,tag,...]:** Specifies the mnemonic name of one or more messages. If you specify more than one mnemonic name, they must be separated by commas. There can be no intervening white space between each "tag". **NOTE** Diagnostic messages generated by this option can be affected by other options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.
`m32` (Linux* only), `m64` (Linux* and macOS) `Qm32`, `Qm64` (Windows*)	`[Q]m32` generates code for IA-32 architecture. Option `-m32` is only available on Linux* systems. `[Q]m64` generates code for Intel® 64 architecture. For example, when your compilation environment is configured for Intel® 64 architecture, and you use [Q]m32 with the compiler, you also need to use `qm32` on the linker command line to make sure the proper compilation target is set up for any IPO compilations or the final link.

Using IPO from the command line

Specify Alternate Tools and Paths

Use the `Qlocation` option to specify an alternate path for a tool. This option accepts two arguments using the following syntax:

Linux and macOS

```
-Qlocation,tool,path
```

Windows

```
/Qlocation,tool,path
```

where *tool* designates which compilation tool is associated with the alternate *path*.

tool	Description
`cpp`	Specifies the preprocessor for the compiler.
`c`	Specifies the Intel® C++ Compiler Classic .
`asm`	Specifies the assembler.
`link`	Specifies the linker.

Use the `Qoption` option to pass an option specified by *optlist* to a *tool*, where *optlist* is a comma-separated list of options. The syntax for this command is:

Linux and macOS

```
-Qoption,tool,optlist
```

Windows

```
/Qoption,tool,optlist
```

where

- *tool* designates which compilation tool receives the *optlist*
- *optlist* indicates one or more valid argument strings for the designated program. If the argument is a command-line option, you must include the hyphen. If the argument contains a space or tab character, the entire argument must be enclosed in quotation characters (""). Separate multiple arguments with commas.

Use Configuration Files

You can decrease the time you spend entering command-line options by using the configuration file to automate command-line entries. Configuration files are automatically processed every time you run the Intel® C++ Compiler Classic. You can insert any valid command-line options into the configuration file. The compiler processes options in the configuration file in the order in which they appear, followed by the specified command-line options when the compiler is invoked.

NOTE
Options in the configuration file are executed every time you run the compiler. If you have varying option requirements for different projects, use Using Response Files .

Sample Configuration Files

The default configuration files `icc.cfg` and `icpc.cfg` (Linux* and macOS) or or `icl.cfg` (Windows*), are located in the same directory as the compiler executable file. If you want to use a different configuration file than the default, you can use the `ICCCFG/ICPCCFG` (for Linux* and macOS) or `ICLCFG` (for Windows) environment variables to specify the location of another configuration file.

NOTE
Anytime you instruct the compiler to use a different configuration file, the default configuration file(s) are ignored.

The following examples illustrate basic configuration files.

Linux

```
## Sample icpc.cfg file
  -I/my_headers
```

Windows

```
## Sample icl.cfg file
  /Ic:\my_headers
```

In the Windows examples, the compiler reads the configuration file and invokes the `I` option every time you run the compiler, along with any options specified on the command line.

Supported Environment Variables
Using Response Files

Use Response Files

You can use response files to:

- Specify options used during particular compilations or projects.
- Save this information in individual files.

Response files are invoked as options on the command line. Options in response files are inserted in the command line at the point where the response file is invoked. Unlike configuration files, which are automatically processed every time you run the compiler, response files must be invoked as an option on the command line. If you create a response file without specifying it on the command line, it will not be invoked.

Sample Response Files

Linux and macOS

```
# response file: response1.txt
# compile with these options
  -w0
# end of response1 file
```

```
# response file: response2.txt
# compile with these options
  -O0
# end of response2 file
```

Windows

```
# response file: response1.txt
# compile with these options
  /W0
# end of response1 file
```

```
# response file: response2.txt
# compile with these options
  /Od
# end of response2 file
```

Use response files to decrease the time spent entering command-line options and to ensure consistency by automating command-line entries. Use individual response files to maintain options for specific projects.

Any number of options or file names can be placed on a line in a response file. Several response files can be referenced in the same command line. The following example shows how to specify a response file on the command line:

macOS

```
icpx @response1.txt prog1.cpp @response2.txt prog2.cpp
```

NOTE
An "at" sign (`@`) must precede the name of the response file on the command line.

Using Configuration Files

Global Symbols and Visibility Attributes for Linux* and macOS

This topic applies to C/C++ applications for Linux* and macOS only.

A global symbol is one that is visible outside the compilation unit (single source file and its include files) in which it is declared. In C/C++, this means anything declared at file level without the `static` keyword. For example:

```
int x = 5;          // global data definition
extern int y;       // global data reference
int five()          // global function definition
  { return 5; }
extern int four(); // global function reference
```

A complete program consists of a main program file and possibly one or more shareable object (`.so`) files that contain the definitions for data or functions referenced by the main program. Similarly, shareable objects might reference data or functions defined in other shareable objects. Shareable objects are so called because if more than one simultaneously executing process has the shareable object mapped into its virtual memory, there is only one copy of the read-only portion of the object resident in physical memory. The main program file and any shareable objects that it references are collectively called the components of the program.

Each global symbol definition or reference in a compilation unit has a visibility attribute that controls how (or if) it may be referenced from outside the component in which it is defined. There are five possible values for visibility:

- **`EXTERNAL`** – The compiler must treat the symbol as though it is defined in another component. For a definition, this means that the compiler must assume that the symbol will be overridden (preempted) by a definition of the same name in another component. See Symbol Preemption. If a function symbol has external visibility, the compiler knows that it must be called indirectly and can inline the indirect call stub.
- **`DEFAULT`** – Other components can reference the symbol. Furthermore, the symbol definition may be overridden (preempted) by a definition of the same name in another component.
- **`PROTECTED`** – Other components can reference the symbol, but it cannot be preempted by a definition of the same name in another component.
- **`HIDDEN`** – Other components cannot directly reference the symbol. However, its address might be passed to other components indirectly (for example, as an argument to a call to a function in another component, or by having its address stored in a data item reference by a function in another component).
- **`INTERNAL`** – The symbol cannot be referenced outside its defining component, either directly or indirectly.

Static local symbols (in C/C++, declared at file scope or elsewhere with the keyword static) usually have `HIDDEN` visibility— they cannot be referenced directly by other components (or, for that matter, other compilation units within the same component), but they might be referenced indirectly.

NOTE
Visibility applies to references as well as definitions. A symbol reference's visibility attribute is an assertion that the corresponding definition will have that visibility.

Specify Symbol Visibility Explicitly

You can explicitly set the visibility of an individual symbol using the `visibility` attribute on a data or function declaration. For example:

```
int i __attribute__ ((visibility("default")));
void __attribute__ ((visibility("hidden"))) x () {...}
extern void y() __attribute__ ((visibility("protected")));
```

The `visibility` declaration attribute accepts one of the five keywords:

- `external`
- `default`
- `protected`
- `hidden`
- `internal`

The value of the `visibility` declaration attribute overrides the default set by the options `-fpic`, `-fvisibility`, or `-fno-common` .

If you have a number of symbols for which you wish to specify the same `visibility` attribute, you can set the visibility using one of the five command line options:

- `-fvisibility-external=`*file*
- `-fvisibility-default=`*file*
- `-fvisibility-protected=`*file*
- `-fvisibility-hidden=`*file*
- `-fvisibility-internal=`*file*

where *file* is the pathname of a file containing a list of the symbol names whose visibility you wish to set.

The symbol names in the file are separated by white space (blanks, TAB characters, or newlines). For example, the command line option: `-fvisibility-protected=prot.txt`, where file `prot.txt` contains:

```
a
    bcd
  e
```

This sets protected visibility for symbols *a*, *b*, *c*, *d*, and *e*.

This has the same effect as `__attribute__ ((visibility=("protected")))` on the declaration for each of the symbols.

NOTE
These two ways to explicitly set visibility are mutually exclusive– you may use `__attribute((visibility()))` on the declaration or specify the symbol name in a file, but not both.

You can set the default visibility for symbols using one of the command line options:

- `-fvisibility=external`
- `-fvisibility=default`
- `-fvisibility=protected`
- `-fvisibility=hidden`
- `-fvisibility=internal`

This option sets the visibility for symbols not specified in a visibility list file and that do not have `__attribute__ ((visibility=()))` in their declaration. For example, the command line options: `-fvisibility=protected -fvisibility-default=prot.txt`, where file `prot.txt` is as previously described, will cause all global symbols except *a*, *b*, *c*, *d*, and *e* to have protected visibility. Those five symbols, however, will have default visibility, and thus will be preemptable.

Save Compiler Information in Your Executable

If you want to save information about the compiler in your executable, use the `[Q]sox` option to save:

- Compiler version number and options used to produce the executable.
- Profile data and inlining information (if optional arguments were specified).

Linux

To view the information stored in the object file, use the `objdump` command. For example:

```
objdump -sj comment a.out
strings -a a.out | grep comment:
```

Windows

To view the linker directives stored in string format in the object file, use the `link` command. For example:

```
link /dump /directives filename.obj
```

In the output, the ?-comment linker directive displays the compiler version information. To search your executable for compiler information, use the `findstr` command. For example, to search for any strings that contain the substring "Compiler":

```
findstr "Compiler" filename.exe
```

Link Debug Information

Linux*

Use option `g` at compile time to tell the compiler to generate symbolic debugging information in the object file.

Use option `gsplit-dwarf` to create a separate object file containing DWARF debug information. Because the DWARF object file is not used by the linker, this reduces the amount of debug information the linker must process and it results in a smaller executable file. See `gsplit-dwarf` for detailed information.

macOS

You can link the DWARF debug information from the object files for an executable using `dsymutil`, a utility included with Xcode*. By linking the debug information in an executable, you eliminate the need to retain object files specifically for debugging purposes.

The utility runs automatically in the following cases:

- When you use the Intel® C++ Compiler to compile directly from source to executable using the command line with option `g`. For example:

Example

```
icc -g myprogram.c
```

- When you compile using Xcode*.

In other cases, you must explicitly run `dsymutil`, such as when you compile using a make file that builds `.o` files and subsequently links the program.

Windows*

Use option `Z7` at compile time or option `debug` at link time to tell the compiler to generate symbolic debugging information in the object file. Alternately, use option `Zi` at link time to generate executables with debug information in the `.pdb` file.

Part V

Optimization and Programming

This section contains information about features related to code optimization and program performance improvement.

OpenMP* Support

The Intel® C++ Compiler Classic supports most of the OpenMP* Application Programming Interface versions 5.0 and 5.1. For the complete OpenMP specification, read the specifications available from the OpenMP web site (http://www.openmp.org; see OpenMP Specifications on that site). The descriptions of OpenMP language characteristics in this documentation often use terms defined in that specification.

The OpenMP API provides symmetric multiprocessing (SMP) with the following major features:

- Relieves you from implementing the low-level details of iteration space partitioning, data sharing, thread creation, scheduling, or synchronization.
- Provides the benefit of performance available from shared memory multiprocessor and multi-core processor systems on all supported Intel architectures, including those processors with Intel® Hyper-Threading Technology (Intel® HT Technology).

The compiler performs transformations to generate multithreaded code based on your placement of OpenMP pragmas in the source program, making it simple to add threading to existing software. The compiler compiles parallel programs and supports the industry-standard OpenMP pragmas.

The compiler provides Intel®-specific extensions to the OpenMP specification including run-time library routines and environment variables. A summary of the compiler options appear in the OpenMP Options Quick Reference.

Parallel Processing with OpenMP

To compile with the OpenMP API, add the pragmas to your code. The compiler processes the code and internally produces a multithreaded version which is then compiled into an executable with the parallelism implemented by threads that execute parallel regions or constructs.

Using Other Compilers

The OpenMP specification does not define interoperability of multiple implementations, so the OpenMP implementation supported by other compilers and OpenMP support in the Intel® C++ Compiler Classic might not be interoperable. Even if you compile and build the entire application with one compiler, be aware that different compilers might not provide OpenMP source compatibility that enable you to compile and link the same set of application sources with a different compiler and get the expected parallel execution results.

Add OpenMP* Support

To add OpenMP* support to your application, do the following:

1. Add the appropriate OpenMP pragmas to your source code.
2. Compile the application with the `/Qopenmp` (Windows*) or `-qopenmp` (Linux* and macOS) option.
3. For applications with large local or temporary arrays, you may need to increase the stack space available at runtime. In addition, you may need to increase the stack allocated to individual threads by using the `OMP_STACKSIZE` environment variable or by setting the corresponding library routines.

You can set other environment variables to control multi-threaded code execution.

OpenMP Pragma Syntax

To add OpenMP support to your application, first declare the OpenMP header and then add appropriate OpenMP pragmas to your source code.

To declare the OpenMP header, add the following in your code:

```
#include <omp.h>
```

OpenMP pragmas use a specific format and syntax. Intel Extension Routines to OpenMP describes the OpenMP extensions to the specification that have been added to the Intel® C++ Compiler Classic.

To use pragmas in your source, use this syntax:

```
<prefix> <pragma> [<clause>, ...] <newline>
```

where:

- *<prefix>* - Required for all OpenMP pragmas. The prefix must be `#pragma omp`.
- *<pragma>* - A valid OpenMP pragma. Must immediately follow the prefix.
- [*<clause>*] - Optional. Clauses can be in any order and repeated as necessary, unless otherwise restricted.
- *<newline>* - A required component of pragma syntax. It precedes the structured block that is enclosed by this pragma.

The pragmas are interpreted as comments if you omit the `/Qopenmp` (Windows) or `-qopenmp` (Linux and macOS) option.

The following example demonstrates one way of using an OpenMP pragma to parallelize a loop:

```
#include <omp.h>
void simple_omp(int *a){
  int i;
  #pragma omp parallel for
  for (i=0; i<1024; i++)
    a[i] = i*2;
}
```

Compile the Application

The `/Qopenmp` (Windows) or `-qopenmp` (Linux and macOS) option enables the parallelizer to generate multi-threaded code based on the OpenMP pragmas in the source. The code can be executed in parallel on single processor, multi-processor, or multi-core processor systems.

The `/Qopenmp` (Windows) or `-qopenmp` (Linux and macOS) option works with both `-O0` (Linux and macOS) and `/Od` (Windows*) and with any optimization level of `O1`, `O2` and `O3`.

Specifying `-O0` (Linux and macOS) or `/Od` (Windows) with the `/Qopenmp` (Windows) or `-qopenmp` (Linux and macOS) option helps to debug OpenMP applications.

Compile your application using a command similar to one of the following:

Linux

```
icpc -qopenmp source_file
```

macOS

```
icpc -qopenmp source_file
```

Windows

```
icl /Qopenmp source_file
```

For example, to compile the previous code example without generating an executable, use the `c` option:

Linux

```
icpc -qopenmp -c parallel.cpp
```

macOS

```
icpc -qopenmp -c parallel.cpp
```

Windows

```
icl /Qopenmp /c parallel.cpp
```

Configure the OpenMP Environment

Before you run the multi-threaded code, you can set the number of desired threads using the OpenMP environment variable, `OMP_NUM_THREADS`.

Supported Environment Variables

Parallel Processing Model

A program containing OpenMP* pragmas begins execution as a single thread, called the initial thread of execution. The initial thread executes sequentially until the first parallel construct is encountered.

The `omp parallel` pragma defines the extent of the parallel construct. When the initial thread encounters a parallel construct, it creates a team of threads, with the initial thread becoming the primary thread of the team. All program statements enclosed by the parallel construct are executed in parallel by each thread in the team, including all routines called from within the enclosed statements.

The statements enclosed lexically within a construct define the static extent of the construct. The dynamic extent includes all statements encountered during the execution of a construct by a thread, including all called routines.

When a thread encounters the end of a structured block enclosed by a parallel construct, the thread waits until all threads in the team have arrived. When that happens the team is dissolved, and only the primary thread continues execution of the code following the parallel construct. The other threads in the team enter a wait state until they are needed to form another team. You can specify any number of parallel constructs in a single program. As a result, thread teams can be created and dissolved many times during program execution.

The following example illustrates, from a high level, the execution model for the OpenMP constructs. The comments in the code explain the structure of each construct or section.

```
main() {                      // Begin serial execution.
  ...                         // Only the initial thread executes
  #pragma omp parallel        // Begin a parallel construct and form a team.
  {
    #pragma omp sections      // Begin a worksharing construct.
    {
       #pragma omp section    // One unit of work.
       {...}
       #pragma omp section    // Another unit of work.
       {...}
    }                         // Wait until both units of work complete.
    ...                       // This code is executed by each team member.
```

```
    #pragma omp for nowait   // Begin a worksharing Construct
    for(...) {               // Each iteration chunk is unit of work.
      ...                    // Work is distributed among the team members.
    }                        // End of worksharing construct.
                             // nowait was specified so threads proceed.
    #pragma omp critical     // Begin a critical section.
    {...}                    // Only one thread executes at a time.
    ...                      // This code is executed by each team member.
    #pragma omp barrier      // Wait for all team members to arrive.
    ...                      // This code is executed by each team member.
  }                          // End of Parallel Construct
                             // Disband team and continue serial execution.
  ...                        // Possibly more parallel constructs.
}                            // End serial execution.
```

Use Orphaned Pragmas

In routines called from within parallel constructs, you can also use pragmas. Pragmas that are not in the static extent of the parallel construct, but are in the dynamic extent, are called orphaned pragmas. Orphaned pragmas allow you to execute portions of your program in parallel with only minimal changes to the sequential version of the program. Using this functionality, you can code parallel constructs at the top levels of your program call tree and use directives to control execution in any of the called routines. For example:

```
int main(void) {
  #pragma omp parallel {
     phase1();
  }
}

void phase1(void) {
  #pragma omp for // This is an orphaned pragma.
  for(i=0; i < n; i++) { some_work(i); }
}
```

This is an orphaned `omp for` loop pragma since the parallel region is not lexically present in routine `phase1`.

Data Environment

You can control the data environment of OpenMP constructs by using data environment clauses supported by the construct. You can also privatize named global-lifetime objects by using the `threadprivate` pragma.

Refer to the OpenMP specification for the full list of data environment clauses. Some commonly used ones include:

- `default`
- `shared`
- `private`
- `firstprivate`
- `lastprivate`
- `reduction`
- `linear`
- `map`

You can use several pragma clauses to control the data scope attributes of variables for the duration of the construct in which you specify them; however, if you do not specify a data scope attribute clause on a pragma, the behavior for the variable is determined by the default scoping rules, which are described in the OpenMP specification, for the variables affected by the directive.

Determine How Many Threads to Use

For applications where the workload depends on application input that can vary widely, delay the decision about the number of threads to employ until runtime when the input sizes can be examined. Examples of workload input parameters that affect the thread count include things like matrix size, database size, image/video size and resolution, depth/breadth/bushiness of tree-based structures, and size of list-based structures. Similarly, for applications designed to run on systems where the processor count can vary widely, defer choosing the number of threads to employ until application runtime when the machine size can be examined.

For applications where the amount of work is unpredictable from the input data, consider using a calibration step to understand the workload and system characteristics to aid in choosing an appropriate number of threads. If the calibration step is expensive, the calibration results can be made persistent by storing the results in a permanent place like the file system.

Avoid simultaneously using more threads than the number of processing units on the system. This situation causes the operating system to multiplex threads on the processors and typically yields sub-optimal performance.

When developing a library as opposed to an entire application, provide a mechanism whereby the user of the library can conveniently select the number of threads used by the library, because it is possible that the user has outer-level parallelism that renders the parallelism in the library unnecessary or even disruptive.

Use the `num_threads` clause on parallel regions to control the number of threads employed and use the `if` clause on parallel regions to decide whether to employ multiple threads at all. The `omp_set_num_threads()` routine can also be used, but it also affects parallel regions created by the calling thread. The `num_threads` clause is local in its effect, so it does not impact other parallel regions. The disadvantages of explicitly setting the number of threads are:

1. In a system with a large number of processors, your application will use some but not all of the processors.
2. In a system with a small number of processors, your application may force over subscription that results in poor performance.

The Intel OpenMP runtime will create the same number of threads as the available number of logical processors unless you use the omp_set_num_threads() routine. To determine the actual limits, use omp_get_thread_limit() and omp_get_max_active_levels(). Developers should carefully consider their thread usage and nesting of parallelism to avoid overloading the system. The `OMP_THREAD_LIMIT` environment variable limits the number of OpenMP threads to use for the whole OpenMP program. The `OMP_MAX_ACTIVE_LEVELS` environment variable limits the number of active nested parallel regions.

Binding Sets and Binding Regions

The binding task set for an OpenMP construct is the set of tasks that are affected by, or provide the context for, the execution of its region. It can be all tasks, the current team tasks, all tasks of the current team that are generated in the region, the binding implicit task, or the generating task.

The binding thread set for an OpenMP construct is the set of threads that are affected by, or provide the context for, the execution of its region. It can be all threads on a device, all threads in a contention group, all primary threads executing an enclosing teams region, the current team, or the encountering thread.

The binding region for an OpenMP construct is the enclosing region that determines the execution context and the scope of the effects of the directive:

- The binding region for an omp ordered construct is the innermost enclosing omp for loop region.
- The binding region for a omp taskwait construct is the innermost enclosing omp task region.
- For all other constructs for which the binding thread set is the current team or the binding task set is the current team tasks, the binding region is the innermost enclosing region.
- For constructs for which the binding task set is the generating task, the binding region is the region of the generating task.

- A omp parallel construct need not be active to be a binding region.
- A construct need not be explicit to be a binding region.
- A region never binds to any region outside of the innermost enclosing parallel region.

Worksharing Using OpenMP*

To get the maximum performance benefit from a processor with multi-core and Intel® Hyper-Threading Technology (Intel® HT Technology), an application needs to be executed in parallel. Parallel execution requires threads, and threading an application is not a simple thing to do; using OpenMP* can make the process a lot easier. Using the OpenMP pragmas, most loops with no loop-carried dependencies can be threaded with one simple statement. This topic explains how to start using OpenMP to parallelize loops, which is also called worksharing.

Options that use OpenMP are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

Most loops can be threaded by inserting one pragma immediately prior to the loop. Further, by leaving the details to the Intel® C++ Compiler Classic and OpenMP, you can spend more time determining which loops should be threaded and how to best restructure the algorithms for maximum performance. The maximum performance of OpenMP is realized when it is used to thread hotspots, the most time-consuming loops in your application.

The power and simplicity of OpenMP is demonstrated by looking at an example. The following loop converts a 32-bit RGB (red, green, blue) pixel to an 8-bit gray-scale pixel. One pragma, which has been inserted immediately before the loop, is all that is needed for parallel execution.

```
#pragma omp parallel for
for (i=0; i < numPixels; i++) {
  pGrayScaleBitmap[i] = (unsigned BYTE)
     (pRGBBitmap[i].red * 0.299 +
      pRGBBitmap[i].green * 0.587 +
      pRGBBitmap[i].blue * 0.114);
}
```

First, the example uses worksharing, which is the general term used in OpenMP to describe distribution of work across threads. When worksharing is used with the `for` construct, as shown in the example, the iterations of the loop are distributed among multiple threads so that each loop iteration is executed exactly once with different iterations executing if there is more than one available threads. The `for` construct on its own only distributes the loop iterations among existing threads. The example uses a `parallel for` construct, which combines `parallel` and `for` constructs to first create a team of threads and then distribute the loop iterations among the threads. Since there is no explicit `num_threads` clause, OpenMP determines the number of threads to create and how to best create, synchronize, and destroy them. OpenMP places the following five restrictions on which loops can be threaded:

- The loop variable must be of type signed or unsigned integer, random access iterator, or pointer.
- The comparison operation must be in the form `loop_variable <, <=, >, >=, or != loop_invariant_expression` of a compatible type.
- The third expression or increment portion of the `for` loop must be either addition or subtraction by a loop invariant value.
- If the comparison operation is < or <=, the loop variable must increment on every iteration; conversely, if the comparison operation is > or >=, the loop variable must decrement on every iteration.
- The loop body must be single-entry-single-exit, meaning no jumps are permitted from inside to outside the loop, with the exception of the `exit` statement that terminates the whole application. If the statements `goto` or `break` are used, the statements must jump within the loop, not outside it. Similarly, for exception handling, exceptions must be caught within the loop.

Although these restrictions might sound somewhat limiting, non-conforming loops can frequently be rewritten to follow these restrictions.

Basics of Compilation

Using the OpenMP pragmas requires an OpenMP-compatible compiler and thread-safe libraries. Adding the `/Qopenmp` (Windows*) or `-qopenmp` (Linux* and macOS) option to the compiler instructs the compiler to pay attention to the OpenMP pragmas and to generate multi-threaded code. If you omit the `/Qopenmp` (Windows) or `-qopenmp` (Linux and macOS) option, the compiler will ignore OpenMP pragmas, which provides a very simple way to generate a single-threaded version without changing any source code. To compile programs containing target and related constructs for offloading to a GPU, the `-fopenmp-targets=spir64` and `/Qopenmp-targets:spir64` flags are needed on Linux and Windows respectively.

For conditional compilation, the compiler defines the `_OPENMP` macro. If needed, the macro can be tested as shown in the following example.

```
#ifdef _OPENMP
   fn();
#endif
```

A Few Simple Examples

The following examples illustrate how simple OpenMP is to use. In common practice, additional issues need to be addressed, but these examples illustrate a good starting point.

In the first example, the loop clips an array to the range from 0 to 255.

```
// clip an array to 0 <= x <= 255
for (i=0; i < numElements; i++) {
  if (array[i] < 0)
  array[i] = 0;
  else if (array[i] > 255)
    array[i] = 255;
}
```

You can thread it using a single OpenMP pragma; insert the pragma immediately prior to the loop:

```
#pragma omp parallel for
for (i=0; i < numElements; i++) {
  if (array[i] < 0)
  array[i] = 0;
  else if (array[i] > 255)
    array[i] = 255;
}
```

In the second example, the loop generates a table of square roots for the numbers from 0 to 100.

```
double value;
double roots[100];
for (value = 0.0; value < 100.0; value ++) { roots[(int)value] = sqrt(value); }
```

Thread the loop by changing the loop variable to a signed integer or unsigned integer and inserting a `#pragma omp parallel for` pragma.

```
int value;
double roots[100];
#pragma omp parallel for
for (value = 0; value < 100; value ++) { roots[value] = sqrt((double)value); }
```

Avoid Data Dependencies and Race Conditions

When a loop meets all five loop restrictions (listed above) and the compiler threads the loop, the loop still might not work correctly due to the existence of data dependencies.

Data dependencies exist when different iterations of a loop (more specifically a loop iteration that is executed on a different thread) read or write the same location in shared memory. Consider the following example that calculates factorials.

```
// Each loop iteration writes a value that a different iteration reads.
#pragma omp parallel for
for (i=2; i < 10; i++) { factorial[i] = i * factorial[i-1]; }
```

The compiler will thread this loop, but the threading will fail because at least one of the loop iterations is data-dependent upon a different iteration. This situation is referred to as a race condition. Race conditions can only occur when using shared resources (like memory) and parallel execution. To address this problem either rewrite the loop or pick a different algorithm, one that does not contain the race condition.

Race conditions are difficult to detect because, for a given case or system, the threads might win the race in the order that happens to make the program function correctly. Because a program works once does not mean that the program will work under all conditions. Testing your program on various machines, some with Intel® Hyper-Threading Technology and some with multiple physical processors, is a good starting point to help identify race conditions.

Traditional debuggers are useless for detecting race conditions because they cause one thread to stop the race while the other threads continue to significantly change the runtime behavior; however, thread checking tools can help.

Manage Shared and Private Data

Nearly every loop (in real applications) reads from or writes to memory; it's your responsibility, as the developer, to instruct the compiler what memory should be shared among the threads and what memory should be kept private. When memory is identified as shared, all threads access the same memory location. When memory is identified as private, however, a separate copy of the variable is made for each thread to access in private. When the loop ends, the private copies are destroyed. By default, all variables are shared except for the loop variable, which is private.

Memory can be declared as private in two ways:

- Declare the variable inside the loop-really inside the parallel OpenMP pragma-without the static keyword.
- Specify the private clause on an OpenMP pragma.

The following loop fails to function correctly because the variable *temp* is shared. It should be private.

```
// Variable temp is shared among all threads, so while one thread
// is reading variable temp another thread might be writing to it
#pragma omp parallel for
for (i=0; i < 100; i++) {
  temp = array[i];
  array[i] = do_something(temp);
}
```

The following two examples both declare the variable *temp* as private memory, which solves the problem.

```
#pragma omp parallel for
for (i=0; i < 100; i++) {
  int temp; // variables declared within a parallel construct
            // are, by definition, private
  temp = array[i];
  array[i] = do_something(temp);
}
```

The *temp* variable can also be made private in the following way:

```
#pragma omp parallel for private(temp)
for (i=0; i < 100; i++) {
  temp = array[i];
  array[i] = do_something(temp);
}
```

Every time you use OpenMP to parallelize a loop, you should carefully examine all memory references, including the references made by called functions. Variables declared within a parallel construct are defined as private except when they are declared with the `static` declarator, because static variables are not allocated on the stack.

Reductions

Loops that accumulate a value are fairly common, and OpenMP has a specific clause to accommodate them. Consider the following loop that calculates the sum of an array of integers.

```
sum = 0;
for (i=0; i < 100; i++) {
  sum += array[i]; // this variable needs to be shared to generate
                   // the correct results, but private to avoid
                   // race conditions from parallel execution
}
```

The variable sum in the previous loop must be shared to generate the correct result, but it also must be private to permit access by multiple threads. OpenMP provides the `reduction` clause that is used to efficiently combine the mathematical reduction of one or more variables in a loop. The following example demonstrates how the loop can use the `reduction` clause to generate the correct results.

```
sum = 0;
#pragma omp parallel for reduction(+:sum)
for (i=0; i < 100; i++) { sum += array[i]; }
```

In the case of the example listed above, the reduction provides private copies of the variable *sum* for each thread, and when the threads exit, it adds the values together and places the result in the one global copy of the variable.

The following table lists the possible reduction operations, along with their initial values (mathematical identity values).

Operation	***private*** **Variable Initialization Value**
+ (addition)	0
- (subtraction)	0
* (multiplication)	1
& (bitwise and)	~0
| (bitwise or)	0
^ (bitwise exclusive or)	0
&& (conditional and)	1
|| (conditional or)	0

Multiple reductions in a loop are possible by specifying comma-separated variables and operations on a given `parallel` construct. Reduction variables must meet the following requirements:

- can be listed in just one reduction.
- cannot be declared constant.
- cannot be declared private in the `parallel` construct.

Load Balancing and Loop Scheduling

Load balancing, the equal division of work among threads, is among the most important attributes for parallel application performance. Load balancing is extremely important, because it ensures that the processors are busy most, if not all, of the time. Without a balanced load, some threads may finish significantly before others, leaving processor resources idle and wasting performance opportunities.

Within loop constructs, poor load balancing is often caused by variations in compute time among loop iterations. It is usually easy to determine the variability of loop iteration compute time by examining the source code. In most cases, you will see that loop iterations consume a uniform amount of time. When that is not true, it may be possible to find a set of iterations that consume similar amounts of time. For example, sometimes the set of all even iterations consumes about as much time as the set of all odd iterations. Similarly, it might be the case that the set of the first half of the loop consumes about as much time as the second half. In contrast, it might be impossible to find sets of loop iterations that have a uniform execution time. Regardless of the case, you should provide this extra loop scheduling information to OpenMP so it can better distribute the iterations of the loop across the threads (and therefore processors) for optimum load balancing.

If you know that all loop iterations consume roughly the same amount of time, the OpenMP `schedule` clause should be used to distribute the iterations of the loop among the threads in roughly equal amounts via the scheduling policy. In addition, you need to minimize the chances of memory conflicts that may arise because of false sharing due to using large chunks. This behavior is possible because loops generally touch memory sequentially, so splitting up the loop in large chunks— like the first half and second half when using two threads— will result in the least chance for overlapping memory. While this may be the best choice for memory issues, it may be bad for load balancing. Unfortunately, the reverse is also true; what might be best for load balancing may be bad for memory performance. You must strike a balance between optimal memory usage and optimal load balancing by measuring the performance to see what method produces the best results.

Use the following general form on the `parallel` construct to schedule an OpenMP loop:

```
#pragma omp parallel for schedule(kind [, chunk size])
```

Four different loop scheduling types (kinds) can be provided to OpenMP, as shown in the following table. The optional parameter (chunk), when specified, must be a positive integer.

Kind	Description
static	Divide the loop into equal-sized chunks or as equal as possible in the case where the number of loop iterations is not evenly divisible by the number of threads multiplied by the chunk size. By default, chunk size is *loop_count*/*number_of_threads*. Set chunk to 1 to interleave the iterations.
dynamic	Use the internal work queue to give a chunk-sized block of loop iterations to each thread. When a thread is finished, it retrieves the next block of loop iterations from the top of the work queue. By default, the chunk size is 1. Be careful when using this scheduling type because of the extra overhead involved.
guided	Similar to dynamic scheduling, but the chunk size starts off large and decreases to better handle load imbalance between iterations. The optional chunk parameter specifies them minimum size chunk to use. By default the chunk size is approximately *loop_count*/*number_of_threads*.

Kind	Description
auto	When schedule (auto) is specified, the decision regarding scheduling is delegated to the compiler. The programmer gives the compiler the freedom to choose any possible mapping of iterations to threads in the team.
runtime	Uses the `OMP_SCHEDULE` environment variable to specify which one of the three loop-scheduling types should be used. `OMP_SCHEDULE` is a string formatted exactly the same as would appear on the parallel construct.

Assume that you want to parallelize the following loop.

```
for (i=0; i < NumElements; i++) {
   array[i] = StartVal;
   StartVal++;
}
```

As written, the loop contains a data dependency, making it impossible to parallelize without a change. The new loop, shown below, fills the array in the same manner, but without data dependencies. The new loop benefits from using the SIMD instructions generated by the compiler.

```
#pragma omp parallel for
for (i=0; i < NumElements; i++)
{
     array[i] = StartVal + i;
}
```

Observe that the code is not 100% identical because the value of variable *StartVal* is not incremented. As a result, when the parallel loop is finished, the variable will have a value different from the one produced by the serial version. If the value of `StartVal` is needed after the loop, the additional statement, shown below, is needed.

```
// This works and is identical to the serial version.
#pragma omp parallel for
for (i=0; i < NumElements; i++)
{
     array[i] = StartVal + i;
}
StartVal += NumElements;
```

OpenMP Tasking Model

The OpenMP tasking model enables parallelization of a large range of applications. A task is an instance of executable code and its data environment that can be scheduled for execution by threads.

The `task` Construct

The `task` construct defines an explicit `task` region as shown in the following example:

```
void test1(LIST *head) {
  #pragma omp parallel shared(head)
  {
    #pragma omp single
     {
      LIST *p = head;
      while (p != NULL) {
        #pragma omp task firstprivate(p)
        {
          do_work1(p);
```

```
      }
      p = p->next;
    }
  }
}
```

The binding thread set of the `task` region is the current parallel team. A `task` region binds to the innermost enclosing `parallel` region. When a thread encounters a `task` construct, a task is generated from the structured block enclosed in the construct. The encountering thread may immediately execute the task, or defer its execution. A `task` construct may be nested inside an outer task, but the `task` region of the inner task is not a part of the `task` region of the outer task.

Use Clauses with the **task** Construct

The `task` construct can take optional clauses. The data environment of the task is created according to the data-sharing attribute clauses on the `task` construct and any defaults that apply. The example below shows a way to generate `N` tasks with one thread and execute the generated tasks with the threads in the parallel team:

```
double data[N];
int i;
#pragma omp parallel shared(data)
{
  #pragma omp single private(i)
  {
    for (i=0, i<N; i++)
    {
      #pragma omp task firstprivate(i) shared(data))
      {
        do_work(data, i);
      }
    }
  }
}
```

Task Scheduling

When a thread reaches a task scheduling point, it may perform a task switch, suspending the current task and beginning or resuming execution of a different task bound to the current team. Refer to the OpenMP 5.1 specifications for the full list of task scheduling point locations. Some examples include:

- the point where a task is explicitly generated.
- the point immediately following the generation of an explicit task.
- after the last instruction of a `task` region.
- in a `taskwait` region.
- in a `taskyield` region.
- in implicit and explicit barrier regions.

NOTE
Task scheduling points dynamically divide `task` regions into parts. Each part is executed from start to finish without interruption. Different parts of the same `task` region are executed in the order in which they are encountered. In the absence of task synchronization constructs, the order in which a thread executes parts of different schedulable tasks is unspecified. A correct program must behave correctly and consistently with all conceivable scheduling sequences.

The **taskwait** Construct

The `taskwait` construct specifies a wait on the completion of child tasks generated since the beginning of the current task. A `taskwait` region binds to the current `task` region. The binding thread set of the `taskwait` region is the current team.

The `taskwait` region includes an implicit task scheduling point in the current `task` region. The current `task` region is suspended at the task scheduling point until execution of all its child tasks generated before the `taskwait` region is completed.

```
#pragma omp task // TASK1
{
  ...
  #pragma omp task // TASK 2 (child of TASK1)
  {
    do_work1();
  }
  #pragma omp task // TASK3 (child of TASK 1)
  {
    ...
    #pragma omp task // TASK4 (child of TASK3, not TASK1)
    {
      do_work2();
    }
    ...
  }
  #pragma omp taskwait // suspend TASK1; wait for TASK2 and TASK3 to complete
  ...
}
```

The `taskyield` Construct

The `taskyield` construct specifies that the current task can be suspended at that point and the thread may switch to the execution of a different task. You can use this construct to provide an explicit task scheduling point at a particular point in the task.

Supported Environment Variables

Control Thread Allocation

The `KMP_HW_SUBSET` and `KMP_AFFINITY` environment variables allow you to control how the OpenMP* runtime uses the hardware threads on the processors. These environment variables allow you to try different thread distributions on the cores of the processors and determine how these threads are bound to the cores. You can use the environment variables to work out what is optimal for your application.

The `KMP_HW_SUBSET` variable controls the allocation of hardware resources and the `KMP_AFFINITY` variable controls how the OpenMP threads are bound to those resources.

Control Thread Distribution

The `KMP_HW_SUBSET` variable controls the hardware resources that will be used by the program. This variable often specifies three layers of machine topology: the number of sockets to use, how many cores to use per socket, and how many threads to use per core. For example, `KMP_HW_SUBSET=2s,12c,2t` means to use two sockets, 12 cores per socket, and two threads per core, giving a total of 48 available hardware threads.

When more layers exist (NUMA domain, tile, etc.) in the machine topology, you can specify those layers as well. For example, `KMP_HW_SUBSET=2s,2n,8c,2t` means to use two sockets, two NUMA domains per socket, eight cores per NUMA domain, and two threads per core, giving a total of 64 available hardware threads. For historical reasons, when a layer is not explicitly specified in KMP_HW_SUBSET, it is assumed you want all the resources in that unspecified layer. You can use `KMP_AFFINITY=verbose` to see all the different detected layers in the machine. For example, `KMP_HW_SUBSET=2s,2t` is interpreted to mean use two sockets, all cores per socket (and possibly all resources of other detected layers as well), and two threads per layer.

When available, you can specify core attributes to choose different sets of cores. The core attributes are appended to the regular core layer specification with a colon (:) and attribute. There are two attributes to help filter types of cores:

1. Core type, specified as `intel_core`, or `intel_atom`.
2. Core efficiency, specified as `eff`*num* where *num* is a non-negative integer from zero to the number of core efficiencies detected minus one. The larger the efficiency the more performant the core. For example, `KMP_HW_SUBSET=4c:eff0,5c:eff1` will select all sockets, four cores of efficiency 0, five cores of efficiency 1, and all threads per those cores.

There is also a special syntax to explicitly request all resources at a specific layer. Instead of specifying a positive integer, you can use an optional asterisk (*). For example, `KMP_HW_SUBSET='*c:eff0'` or `KMP_HW_SUBSET=c:eff0` will request all the cores of efficiency 0.

Consider a system with 24 cores and four hardware threads per core. While specifying two threads per core often yields better performance than one thread per core, specifying three or four threads per core may or may not improve the performance. This variable enables you to conveniently measure the performance of up to four threads per core.

For example, you can determine the effects of assigning 24, 48, 72, or the maximum 96 OpenMP threads in a system with 24 cores by specifying the following variable settings:

To Assign This Number of Threads ...	... Use This Setting
24	`KMP_HW_SUBSET=24c,1t`
48	`KMP_HW_SUBSET=24c,2t`
72	`KMP_HW_SUBSET=24c,3t`
96	`KMP_HW_SUBSET=24c,4t`

Caution
Take care when using the `OMP_NUM_THREADS` variable along with this variable. Using the `OMP_NUM_THREADS` variable can result in over or under subscription.

NOTE
If you use `KMP_HW_SUBSET` to specify more resources than the system has, the runtime will issue a warning and ignore the setting. For example, setting `KMP_HW_SUBSET=24c,5t` will be ignored on a system where each core has four hardware threads.

Control Thread Bindings

The `KMP_AFFINITY` variable controls how the OpenMP threads are bound to the hardware resources allocated by the `KMP_HW_SUBSET` variable. While this variable can be set to several binding or affinity types, the following are the recommended affinity types to use to run your OpenMP threads on the processor:

- *compact*: Distribute the threads sequentially among the cores.
- *scatter*: Distribute the threads among the cores in a round robin manner. Distribution is one thread per core initially, followed by repeat distribution among the cores.

The following table shows how the threads are bound to the cores when you want to use three threads per core on two cores by specifying `KMP_HW_SUBSET=2c,3t`:

Affinity	OpenMP Threads on Core 0	OpenMP Threads on Core 1
`KMP_AFFINITY=compact`	0, 1, 2	3, 4, 5
`KMP_AFFINITY=scatter`	0, 2, 4	1, 3, 5

Determine the Best Setting

To determine the best thread distribution and bindings using these variables, use the following:

1. Ensure that your OpenMP code is working properly before using these environment variables.
2. Establish a baseline with your current OpenMP code to compare to the performance when you allocate the threads to a processor.
3. Measure the performance of distributing one, two, three, or four threads per core by use the `KMP_HW_SUBSET` variable.
4. Measure the performance of binding the threads to the cores by using the `KMP_AFFINITY` variable.

Supported Environment Variables

OpenMP* Pragmas

This is a summary of the OpenMP* pragmas supported in the Intel® C++ Compiler Classic. For detailed information about the OpenMP API, see the *OpenMP Application Program Interface* Version 5.1 specification, which is available from the OpenMP web site.

PARALLEL Pragma

Use this pragma to form a team of threads and execute those threads in parallel.

Pragma	Description
omp parallel	Specifies that a structured block should be run in parallel by a team of threads.

TASKING Pragma

Use these pragmas for deferring execution.

Pragma	Description
omp task	Specifies a code block whose execution may be deferred.

Pragma	Description
omp taskloop	Specifies that the iterations of one or more associated for loops should be executed using OpenMP tasks. The iterations are distributed across tasks that are created by the construct and scheduled to be executed in parallel by the current team.

WORKSHARING Pragmas

Use these pragmas to share work among a team of threads.

Pragma	Description
omp for	Specifies a work-sharing loop. Iterations of the loop are executed in parallel by the threads in the team.
omp sections	Defines a set of structured blocks that will be distributed among the threads in the team.
omp single	Specifies that a block of code is to be executed by only one thread in the team.

SYNCHRONIZATION Pragmas

Use these pragmas to synchronize between threads.

Pragma	Description
omp atomic	Specifies a computation that must be executed atomically.
omp barrier	Specifies a point in the code where each thread must wait until all threads in the team arrive.
omp critical	Specifies a code block that is restricted to access by only one thread at a time.
omp flush	Identifies a point at which a thread's temporary view of memory becomes consistent with the memory.
omp master	Specifies a code block that must be executed only once by the primary thread of the team.
omp ordered	Specifies a block of code that the threads in a team must execute in the natural order of the loop iterations, or as a stand-alone directive, specifies cross-iteration dependences in a doacross loop-nest. The following clauses are available as Intel-specific extensions of the OpenMP* specification: `monotonic` Specifies a block of code in which the value of the new list item on each iteration of the associated SIMD loop(s) corresponds to the value of the original list item before entering the associated loop, plus the number of the iterations for which the conditional update happens prior to the current iteration, times linear-step. The value corresponding to the sequentially last iteration of the associated loop(s) is assigned to the original list item. Use with the `simd` clause.

Pragma	Description
	`overlap` Specifies a block of code that has to be executed scalar for overlapping `inx` values and parallel for different `inx` values within SIMD loop. Use with the `simd` clause.
omp taskgroup	Causes the program to wait until the completion of all enclosed and descendant tasks.
omp taskwait	Specifies a wait on the completion of child tasks generated since the beginning of the current task.
omp taskyield	Specifies that the current task can be suspended at this point in favor of execution of a different task.

Data Environment Pragmas

Use these pragmas to affect the data environment.

Pragma	Description
omp scan	Specifies a scan computation that updates each list item in each iteration of the loop.
omp threadprivate	Specifies a list of globally-visible variables that will be allocated private to each thread.

Offload Target Control Pragmas

Use these pragmas to control execution on one or more offload targets.

Pragma	Description
omp distribute	Specifies that the iterations of one or more loops should be distributed among the initial threads of all thread teams in a league.
omp target enter data	
omp target exit data	
omp teams	Creates a league of thread teams inside a target region to execute a structured block in the initial thread of each team.

Vectorization Pragmas

Use these pragmas to control execution on vector hardware.

Pragma	Description
omp simd	Transforms the loop into a loop that will be executed concurrently using SIMD instructions. The `early_exit` clause is an Intel-specific extension of the OpenMP* specification. `early_exit`

Pragma	Description
	Allows vectorization of multiple exit loops. When this clause is specified: • Each operation before last lexical early exit of the loop may be executed as if early exit were not triggered within the SIMD chunk. • After the last lexical early exit of the loop, all operations are executed as if the last iteration of the loop was found. • Each list item specified in the `linear` clause is computed based on the last iteration number upon exiting the loop. • The last value for `linear` clauses and conditional `lastprivates` clauses are preserved with respect to scalar execution. • The last value for `reductions` clauses are computed as if the last iteration in the last SIMD chunk was executed up on exiting the loop. • The shared memory state may not be preserved with regard to scalar execution. • Exceptions are not allowed.
omp declare simd	Creates a version of a function that can process multiple arguments using Single Instruction Multiple Data (SIMD) instructions from a single invocation from a SIMD loop.

Cancellation Constructs

Pragma	Description
omp cancel	Requests cancellation of the innermost enclosing region of the type specified, and causes the encountering task to proceed to the end of the cancelled construct.
omp cancellation point	Defines a point at which implicit or explicit tasks check to see if cancellation has been requested for the innermost enclosing region of the type specified. This construct does not implement a synchronization between threads or tasks.

User-Defined Reduction Pragma

Use this pragma to define reduction identifiers that can be used as reduction operators in a reduction clause.

Pragma	Description
omp declare reduction	Declares User-Defined Reduction (UDR) functions (reduction identifiers) that can be used as reduction operators in a reduction clause.

Combined and Composite Pragmas

Use these pragmas as shortcuts for multiple pragmas in sequence. A combined construct is a shortcut for specifying one construct immediately nested inside another construct. A combined construct is semantically identical to that of explicitly specifying the first construct containing one instance of the second construct and no other statements.

A composite construct is composed of two constructs but does not have identical semantics to specifying one of the constructs immediately nested inside the other. A composite construct either adds semantics not included in the constructs from which it is composed or the nesting of the one construct inside the other is not conforming.

Pragma	Description
omp distribute parallel for [1]	Specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams.
omp distribute parallel for simd[1]	Specifies a loop that will be executed in parallel by multiple threads that are members of multiple teams. It will be executed concurrently using SIMD instructions.
omp distribute simd [1]	Specifies a loop that will be distributed across the primary threads of the teams region. It will be executed concurrently using SIMD instructions.
omp for simd[1]	Specifies that the iterations of the loop will be distributed across threads in the team. Iterations executed by each thread can also be executed concurrently using SIMD instructions.
omp parallel for	Provides an abbreviated way to specify a parallel region containing only a FOR construct.
omp parallel for simd	Specifies a parallel construct that contains one for simd construct and no other statement.
omp parallel sections	Specifies a parallel construct that contains only a sections construct.
	Creates a device data environment and executes the parallel region on that device.
	Provides an abbreviated way to specify a target construct that contains an omp target parallel for construct and no other statement between them.
	Specifies a target construct that contains an omp target parallel for simd construct and no other statement between them.
	Specifies a target construct that contains an omp simd construct and no other statement between them.
omp target teams	Creates a device data environment and executes the construct on the same device. It also creates a league of thread teams with the primary thread in each team executing the structured block.
omp target teams distribute	Creates a device data environment and then executes the construct on that device. It also specifies that loop iterations will be distributed among the primary threads of all thread teams in a league created by a teams construct.
omp target teams distribute parallel for	Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a teams construct.

Pragma	Description
omp target teams distribute parallel for simd	Creates a device data environment and then executes the construct on that device. It also specifies a loop that can be executed in parallel by multiple threads that are members of multiple teams created by a teams construct. The loop will be distributed across the teams, which will be executed concurrently using SIMD instructions.
omp target teams distribute simd	Creates a device data environment and then executes the construct on that device. It also specifies that loop iterations will be distributed among the primary threads of all thread teams in a league created by a teams construct. It will be executed concurrently using SIMD instructions.
omp taskloop simd [1]	Specifies a loop that can be executed concurrently using SIMD instructions and that those iterations will also be executed in parallel using OpenMP* tasks.
omp teams distribute	Creates a league of thread teams and specifies that loop iterations will be distributed among the primary threads of all thread teams in the league.
omp teams distribute parallel for	Creates a league of thread teams and specifies that the associated loop can be executed in parallel by multiple threads that are members of multiple teams.
omp teams distribute parallel for simd	Creates a league of thread teams and specifies that the associated loop can be executed concurrently using SIMD instructions in parallel by multiple threads that are members of multiple teams.
omp teams distribute simd	Creates a league of thread teams and specifies that the associated loop will be distributed across the primary threads of the teams and executed concurrently using SIMD instructions.

Footnotes:

[1] This directive specifies a composite construct.

OpenMP* Library Support

This section provides information about OpenMP* run-time library routines, Intel® compiler extension routines to OpenMP, OpenMP support libraries and how to use them, and the thread affinity interface.

OpenMP* Run-time Library Routines

OpenMP* provides run-time library routines to help you manage your program in parallel mode. Many of these run-time library routines have corresponding environment variables that can be set as defaults. The run-time library routines let you dynamically change these factors to assist in controlling your program. In all cases, a call to a run-time library routine overrides any corresponding environment variable.

> **Caution**
> Running OpenMP runtime library routines may initialize the OpenMP runtime environment, which might cause a situation where subsequent programmatic setting of OpenMP environment variables has no effect. To avoid this situation, you can use the Intel extension routine `kmp_set_defaults()` to set OpenMP environment variables.

The compiler supports all the OpenMP run-time library routines. Refer to the OpenMP API specification for detailed information about using these routines.

Include the appropriate declarations of the routines in your source code by adding a statement similar to the following:

```
#include <omp.h>
```

The header files are provided in the `../include` (Linux* and macOS) or `..\include` (Windows*) directory of your compiler installation.

Thread Team Routines

Routines that affect and monitor thread teams in the current contention group.

Routine	Description
`void omp_set_num_threads(int nthreads)`	Sets the number of threads to use for subsequent parallel regions created by the calling thread.
`int omp_get_num_threads(void)`	Returns the number of threads that are being used in the current parallel region. This function does not necessarily return the value inherited by the calling thread from the `omp_set_num_threads()` function.
`int omp_get_max_threads(void)`	Returns the number of threads available to subsequent parallel regions created by the calling thread.
`int omp_get_thread_num(void)`	Returns the thread number of the calling thread, within the context of the current parallel region.
`int omp_in_parallel(void)`	Returns `TRUE` if called within the dynamic extent of a parallel region executing in parallel; otherwise returns `FALSE`.
`void omp_set_dynamic(int dynamic_threads)`	Enables or disables dynamic adjustment of the number of threads used to execute a parallel region. If `dynamic_threads` is `TRUE`, dynamic threads are enabled. If `dynamic_threads` is `FALSE`, dynamic threads are disabled. Dynamic threads are disabled by default.
`int omp_get_dynamic(void)`	Returns `TRUE` if dynamic thread adjustment is enabled, otherwise returns `FALSE`.
`int omp_get_cancellation(void)`	Returns `TRUE` if cancellation is enabled, otherwise returns `FALSE`. This routine can be affected by the setting for environment variable `OMP_CANCELLATION`.

Routine	Description
`void omp_set_nested(int nested)` **NOTE** This has been deprecated.	Enables or disables nested parallelism. If `nested` is `TRUE`, nested parallelism is enabled. If `nested` is `FALSE`, nested parallelism is disabled. Nested parallelism is disabled by default.
`int omp_get_nested(void)` **NOTE** This has been deprecated.	Returns `TRUE` if nested parallelism is enabled, otherwise returns `FALSE`.
`void omp_set_schedule(omp_sched_t kind,int chunk_size)`	Determines the schedule of a worksharing loop that is applied when '`runtime`' is used as the schedule kind.
`void omp_get_schedule(omp_sched_kind *kind,int *chunk_size)`	Returns the schedule of a worksharing loop that is applied when the '`runtime`' schedule is used.
`int omp_get_thread_limit(void)`	Returns the maximum number of simultaneously executing threads in an OpenMP program.
`int omp_get_supported_active_levels(void)`	Returns the number of active levels of parallelism supported by the implementation.
`void omp_set_max_active_levels(int max_active_levels)`	Limits the number of nested active parallel regions. The value of `max_active_levels` must evaluate to a non-negative integer.
`int omp_get_max_active_levels(void)`	Returns the maximum number of nested active parallel regions.
`int omp_get_level(void)`	Returns the number of nested parallel regions (whether active or inactive) enclosing the task that contains the call, not including the implicit parallel region.
`int omp_get_ancestor_thread_num(int level)`	Returns the thread number of the ancestor at a given nest level of the current thread.
`int omp_get_team_size(int level)`	Returns the size of the thread team to which the ancestor or the current thread belongs for a given nested level.
`int omp_get_active_level(void)`	Returns the number of nested, active parallel regions enclosing the task that contains the call.

Thread Affinity Routines

Routines that affect and access thread affinity policies that are in effect.

Function	Description
omp_proc_bind_t omp_get_proc_bind(void)	Returns the currently active thread affinity policy, which can be initialized by the environment variable OMP_PROC_BIND. This policy is used for subsequent nested parallel regions.
int omp_get_num_places(void)	Returns the number of places available to the execution environment in the place list of the initial task, usually threads, cores, or sockets.
int omp_get_place_num_procs(int place_num)	Returns the number of processors associated with the place numbered place_num. The routine returns zero when place_num is negative or is greater than or equal to omp_get_num_places().
void omp_get_place_proc_ids(int place_num, int *ids)	Returns the numerical identifiers of each processor associated with the place numbered place_num. The numerical identifiers are non-negative and their meaning is implementation defined. The numerical identifiers are returned in the array ids and their order in the array is implementation defined.The array ids must be sufficiently large to contain omp_get_place_num_procs(place_num) elements. The routine has no effect when place_num is negative or greater than or equal to omp_get_num_places().
int omp_get_place_num(void)	Returns the place number of the place to which the encountering thread is bound. The returned value is between 0 and omp_get_num_places() - 1, inclusive. When the encountering thread is not bound to a place, the routine returns -1.
int omp_get_partition_num_places(void)	Returns the number of places in the place partition of the innermost implicit task.
void omp_get_partition_place_nums(int *place_nums)	Returns the list of place numbers corresponding to the places in the place-partition-var ICV of the innermost implicit task. The array place_nums must be sufficiently large to contain omp_get_partition_num_places() elements.
void omp_set_affinity_format(const char *format)	Sets the affinity format to be used on the device by setting the value of the affinity-format-var ICV.
size_t omp_get_affinity_format(char *buffer, size_t size)	Returns the value of the affinity-format-var ICV on the device.
void omp_display_affinity(const char *format)	Prints the OpenMP thread affinity information using the format specification provided.
size_t omp_capture_affinity(char *buffer, size_t size, const char *format)	Prints the OpenMP thread affinity information into a buffer using the format specification provided.

Teams Region Routines

Routines that affect and monitor the league of teams that may execute a teams region.

Function	Description
`int omp_get_num_teams(void)`	Returns the number of initial teams in the current teams region.
`int omp_get_team_num(void)`	Returns the initial team number of the calling thread.
`void omp_set_num_teams(int num_teams)`	Affects the number of threads to be used for subsequent teams regions that do not specify a `num_teams` clause.
`int omp_get_max_teams(void)`	Returns an upper bound on the number of teams that could be created by a teams construct without a `num_teams` clause that is encountered after execution returns from this routine.
`void omp_set_teams_thread_limit(int thread_limit)`	Defines the maximum number of OpenMP threads that can participate in each contention group created by a teams construct.
`int omp_get_teams_thread_limit(void)`	Returns the maximum number of OpenMP threads available to participate in each contention group created by a teams construct.

Tasking Routines

Routines that pertain to OpenMP explicit tasks.

Function	Description
`int omp_get_max_task_priority(void)`	Returns the maximum value that can be specified in the `priority` clause.
`int omp_in_explicit_task(void)`	Returns `TRUE` if called within an explicit task region; otherwise returns `FALSE`.
`int omp_in_final(void)`	Returns `TRUE` if called within a final task region; otherwise returns `FALSE`.

Resource Relinquishing Routines

Routines that relinquish resources used by the OpenMP runtime. These routines are only effective on the host device.

Function	Description
`int omp_pause_resource(omp_pause_resource_t kind, int device_num)`	Allows the runtime to relinquish resources used by OpenMP on the specified device. The routine returns zero in case of success, and non-zero otherwise.
`int omp_pause_resource_all(omp_pause_resource_t kind)`	Allows the runtime to relinquish resources used by OpenMP on all devices. The routine returns zero in case of success, and non-zero otherwise.

Device Information Routines

Routines that pertain to the set of devices that are accessible to an OpenMP program.

Function	Description
`int omp_get_num_procs(void)`	Returns the number of processors available to the program.
`void omp_set_default_device(int device_number)`	Sets the default device number.
`int omp_get_default_device(void)`	Returns the default device number.
`int omp_get_num_devices(void)`	Returns the number of target devices.
`int omp_get_device_num(void)`	Returns the device number of the device on which the calling thread is executing.
`int omp_is_initial_device(void)`	Returns `TRUE` if the current task is running on the host device; otherwise, `FALSE`.
`int omp_get_initial_device(void)`	Returns the device number of the host device. The value of the device number is implementation defined. If it is between 0 and `omp_get_num_devices()`-1, then it is valid in all device constructs and routines; if it is outside that range, then it is only valid in the device memory routines and not in the `device` clause.

Lock Routines

Use these routines to affect OpenMP locks.

Function	Description
`void omp_init_lock(omp_lock_t *lock)`	Initializes the lock to the unlocked state.
`void omp_init_nest_lock(omp_nest_lock_t *lock)`	Initializes the nested lock to the unlocked state. The nesting count for the nested lock is set to zero.
`void omp_init_lock_with_hint(omp_lock_t *lock, omp_sync_hint_t hint)`	Initializes the lock to the unlocked state, optionally choosing a specific lock implementation based on `hint`. See the OpenMP specification for the available hints.
`void omp_init_nest_lock_with_hint(omp_nest_lock_t *lock, omp_sync_hint_t hint)`	Initializes the nested lock to the unlocked state, optionally choosing a specific lock implementation based on `hint`. The nesting count for the nested lock is set to zero. See the OpenMP specification for the available hints.
`void omp_destroy_lock(omp_lock_t *lock)`	Changes the state of the lock to uninitialized.
`void omp_destroy_nest_lock(omp_nest_lock_t *lock)`	Changes the state of the nested lock to uninitialized.

Function	Description
`void omp_set_lock(omp_lock_t *lock)`	Forces the executing thread to wait until the lock is available. The thread is granted ownership of the lock when it becomes available.
`void omp_set_nest_lock(omp_nest_lock_t *lock)`	Forces the executing thread to wait until the nested lock is available. If the thread already owns the lock, then the lock nesting count is incremented.
`void omp_unset_lock(omp_lock_t *lock)`	Releases the executing thread from ownership of the lock. The behavior is undefined if the executing thread does not own the lock.
`void omp_unset_nest_lock(omp_nest_lock_t *lock)`	Decrements the nesting count for the nested lock and releases the executing thread from ownership of the nested lock if the resulting nesting count is zero. Behavior is undefined if the executing thread does not own the nested lock.
`int omp_test_lock(omp_lock_t *lock)`	Attempts to set the lock. If successful, returns `TRUE`, otherwise returns `FALSE`.
`int omp_test_nest_lock(omp_nest_lock_t *lock)`	Attempts to set the nested lock. If successful, returns the nesting count, otherwise returns zero.

Timing Routines

Function	Description
`double omp_get_wtime(void)`	Returns a double precision value equal to the elapsed wall clock time (in seconds) relative to an arbitrary reference time. The reference time does not change during program execution.
`double omp_get_wtick(void)`	Returns a double precision value equal to the number of seconds between successive clock ticks.

Event Routines

Function	Description
`void omp_fulfill_event(omp_event_handle_t event)`	Fulfills the event associated with the event handle `event` and destroys the event.

Memory Management Routines

Function	Description
`omp_allocator_handle_t omp_init_allocator(omp_memspace_handle_t memspace, int ntraits, const omp_alloctrait_t traits[])`	Creates a new allocator that is associated with the `memspace` memory space and returns a handle to it.

Function	Description
void omp_destroy_allocator(omp_allocator_handle_t allocator)	Releases all resources used to implement the allocator handle.
void omp_set_default_allocator(omp_allocator_handle_t allocator)	Sets the default memory allocator to be used by allocation calls, allocate directives and allocate clauses that do not specify an allocator.
omp_allocator_handle_t omp_get_default_allocator(void)	Returns a handle to the memory allocator to be used by allocation calls, allocate directives and allocate clauses that do not specify an allocator.
void *omp_alloc(size_t size, omp_allocator_handle_t allocator)	Requests a memory allocation of size bytes from the specified memory allocator.
void *omp_aligned_alloc(size_t alignment, size_t size, omp_allocator_handle_t allocator)	Requests a memory allocation of `size` bytes from the specified memory allocator. Memory allocated by `omp_aligned_alloc` will be byte-aligned to at least the maximum of the alignment required by malloc, the alignment trait of the allocator and the alignment argument value.
void omp_free(void *ptr, omp_allocator_handle_t allocator)	Deallocates the memory to which `ptr` points. The `ptr` argument must have been returned by an OpenMP allocation routine.
void *omp_calloc(size_t nmemb, size_t size, omp_allocator_handle_t allocator)	Requests a memory allocation from the specified memory allocator for an array of `nmemb` elements each of which has a size of `size` bytes.
void *omp_aligned_calloc(size_t alignment, size_t nmemb, size_t size, omp_allocator_handle_t allocator)	Requests a memory allocation from the specified memory allocator for an array of `nmemb` elements each of which has a size of `size` bytes. Memory allocated by `omp_aligned_calloc` will be byte-aligned to at least the maximum of the alignment required by malloc, the alignment trait of the allocator and the alignment argument value.
void *omp_realloc(void *ptr, size_t size, omp_allocator_handle_t allocator, omp_allocator_handle_t free_allocator)	Deallocates the memory to which `ptr` points and requests a new memory allocation of `size` bytes from the specified memory allocator. Upon success it returns a pointer to the allocated memory and the contents of the new object shall be the same as that of the old object prior to deallocation up to the minimum size of old allocated size and `size` argument.

Tool Control Routines

Function	Description
int omp_control_tool(int command, int modifier, void *arg)	Enables a program to pass commands to an active tool.

Environment Display Routines

Function	Description
`void omp_display_env(int verbose)`	Displays the OpenMP version number and the initial values of ICVs associated with the environment variables.

Intel Extension Routines to OpenMP*

Intel® Compiler Extension Routines to OpenMP*

The Intel® compiler implements the following group of routines as extensions to the OpenMP* run-time library:

- Get and set the execution environment
- Get and set the stack size for parallel threads
- Memory allocation
- Get and set the thread sleep time for the throughput execution mode
- Target memory allocation

The Intel® extension routines described in this section can be used for low-level tuning to verify that the library code and application are functioning as intended. These routines are generally not recognized by other OpenMP-compliant compilers, which may cause the link stage to fail in the other compiler. To execute these OpenMP routines, use the `/Qopenmp-stubs` (Windows*) or `-qopenmp-stubs` (Linux* and macOS) option.

In most cases, environment variables can be used in place of the extension library routines. For example, the stack size of the parallel threads may be set using the `OMP_STACKSIZE` environment variable rather than the `kmp_set_stacksize_s()` library routine.

NOTE
A run-time call to an Intel extension routine takes precedence over the corresponding environment variable setting.

Execution Environment

Function	Description
`void kmp_set_defaults(char const *)`	Sets OpenMP environment variables defined as a list of variables separated by "**|**" in the argument.
`void kmp_set_library_throughput(void)`	Sets execution mode to throughput, which is the default. Allows the application to determine the runtime environment. Use in multi-user environments.
`void kmp_set_library_turnaround(void)`	Sets execution mode to turnaround. Use in dedicated parallel (single user) environments.
`void kmp_set_library_serial(void)`	Sets execution mode to serial.
`void kmp_set_library(int)`	Sets execution mode indicated by the value passed to the function. Valid values are: • **1** - serial mode • **2** - turnaround mode

Function	Description
	• **3** - throughput mode Call this routine before the first parallel region is executed.
`int kmp_get_library(void)`	Returns a value corresponding to the current execution mode: • **1** - serial • **2** - turnaround • **3** - throughput

Stack Size

Function	Description
`size_t kmp_get_stacksize_s(void)`	Returns the number of bytes that will be allocated for each parallel thread to use as its private stack. This value can be changed with `kmp_set_stacksize_s()` routine, prior to the first parallel region or via the `KMP_STACKSIZE` environment variable.
`int kmp_get_stacksize(void)`	Provided for backwards compatibility only. Use `kmp_get_stacksize_s()` routine for compatibility across different families of Intel processors.
`void kmp_set_stacksize_s(size_t`*`size`*`)`	Sets to *size* the number of bytes that will be allocated for each parallel thread to use as its private stack. This value can also be set via the `KMP_STACKSIZE` environment variable. In order for `kmp_set_stacksize_s()` to have an effect, it must be called before the beginning of the first (dynamically executed) parallel region in the program.
`void kmp_set_stacksize(int `*`size`*`)`	Provided for backward compatibility only. Use `kmp_set_stacksize_s()` for compatibility across different families of Intel® processors.

Memory Allocation

The Intel® compiler implements a group of memory allocation routines as an extension to the OpenMP run-time library to enable threads to allocate memory from a heap local to each thread. These routines are: `kmp_malloc()`, `kmp_calloc()`, and `kmp_realloc()`.

The memory allocated by these routines must also be freed by the `kmp_free()` routine. While you can allocate memory in one thread and then free that memory in a different thread, this mode of operation incurs a slight performance penalty.

Function	Description
`void* kmp_malloc(size_t `*`size`*`)`	Allocate memory block of *size* bytes from thread-local heap.

Function	Description
`void* kmp_calloc(size_t nelem, size_t elsize)`	Allocate array of *nelem* elements of size *elsize* from thread-local heap.
`void* kmp_realloc(void* ptr, size_t size)`	Reallocate memory block at address *ptr* and *size* bytes from thread-local heap.
`void* kmp_free(void* ptr)`	Free memory block at address *ptr* from thread-local heap. Memory must have been previously allocated with `kmp_malloc()`, `kmp_calloc()`, or `kmp_realloc()`.

Thread Sleep Time

In the throughput OpenMP* Support Libraries, threads wait for new parallel work at the ends of parallel regions, and then sleep, after a specified period of time. This time interval can be set by the `KMP_BLOCKTIME` environment variable or by the `kmp_set_blocktime()` function.

Function	Description
`int kmp_get_blocktime(void)`	Returns the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping, as set either by the `KMP_BLOCKTIME` environment variable or by `kmp_set_blocktime()`.
`void kmp_set_blocktime(int msec)`	Sets the number of milliseconds that a thread should wait, after completing the execution of a parallel region, before sleeping. This routine affects the block time setting for the calling thread and any OpenMP team threads formed by the calling thread. The routine does not affect the block time for any other threads.

OpenMP* Support Libraries

OpenMP* Support Libraries

The Intel® C++ Compiler Classic provides support libraries for OpenMP*. There are several kinds of libraries:

- **Performance:** supports parallel OpenMP execution.
- **Stubs:** supports serial execution of OpenMP applications.

Each kind of library is available for both dynamic and static linking on Linux* and macOS operating systems. Only dynamic linking is supported on Windows* operating systems.

Performance Libraries

To use these libraries, specify the `/Qopenmp` (Windows*) or `-qopenmp` (Linux* and macOS) option.

Options that use OpenMP are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

Operating System	Dynamic Link	Static Link
Linux	`libiomp5.so`	`libiomp5.a`
macOS	`libiomp5.dylib`	`libiomp5.a`
Windows	`libiomp5md.lib` `libiomp5md.dll`	None

Many routines in the OpenMP support libraries are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Stubs Libraries

To use these libraries, specify `/Qopenmp-stubs` (Windows*) or `-qopenmp-stubs` (Linux* and macOS) option. These allow you to compile OpenMP applications in serial mode and provide stubs for OpenMP routines and extended Intel-specific routines.

Operating System	Dynamic Link	Static Link
Linux	`libiompstubs5.so`	`libiompstubs5.a`
macOS	`libiompstubs5.dylib`	`libiompstubs5.a`
Windows	`libiompstubs5md.lib` `libiompstubs5md.dll`	None

Execution Modes

The compiler enables you to run an application under different execution modes specified at run time; the libraries support the turnaround, throughput, and serial modes. Use the `KMP_LIBRARY` environment variable to select the modes at run time.

Mode	Description
throughput (default)	The throughput mode allows the program to yield to other running programs and adjust resource usage to produce efficient execution in a dynamic environment. In a multi-user environment where the load on the parallel machine is not constant or where the job stream is not predictable, it may be better to design and tune for throughput. This minimizes the total time to run multiple jobs simultaneously. In this mode, the worker threads yield to other threads while waiting for more parallel work. After completing the execution of a parallel region, threads wait for new parallel work to become available. After a certain period of time has elapsed, they stop waiting and sleep. Until more parallel work becomes available, sleeping allows processor and resources to be used for other work by non-OpenMP threaded code that may execute between parallel regions, or by other applications.

Mode	Description
turnaround	The amount of time to wait before sleeping is set either by the `KMP_BLOCKTIME` environment variable or by the `kmp_set_blocktime()` function. A small blocktime value may offer better overall performance if your application contains non-OpenMP threaded code that executes between parallel regions. A larger blocktime value may be more appropriate if threads are to be reserved solely for use for OpenMP execution, but may penalize other concurrently-running OpenMP or threaded applications. The turnaround mode is designed to keep active all processors involved in the parallel computation, which minimizes execution time of a single job. In this mode, the worker threads actively wait for more parallel work, without yielding to other threads (although they are still subject to `KMP_BLOCKTIME` control). In a dedicated (batch or single user) parallel environment where all processors are exclusively allocated to the program for its entire run, it is most important to effectively use all processors all of the time. **NOTE** Avoid over-allocating system resources. The condition can occur if either too many threads have been specified, or if too few processors are available at run time. If system resources are over-allocated, this mode will cause poor performance. The throughput mode should be used instead if this occurs.
serial	The serial mode forces parallel applications to run as a single thread.

Use the OpenMP Libraries

This section describes the steps needed to set up and use the OpenMP Libraries from the command line. On Windows systems, you can also build applications compiled with the OpenMP libraries in the Microsoft Visual Studio development environment.

For a list of the options and libraries used by the OpenMP libraries, see OpenMP Support Libraries.

Set Up Environment

Set up your environment for access to the compiler to ensure that the appropriate OpenMP library is available during linking.

Linux and macOS

On Linux and macOS systems you can source the appropriate script file (`compilervars` file).

Windows

On Windows systems you can either execute the appropriate batch (`.bat`) file or use the command-line window supplied in the compiler program folder that already has the environment set up.

During compilation, ensure that the version of `omp.h` used when compiling is the version provided by that compiler. For example, use the `omp.h` provided with GCC when you compile with GCC.

Caution
Be aware that when using the GCC or Microsoft Compiler, you may inadvertently use inappropriate header or module files. To avoid this, copy the header or module file(s) to a separate directory and put it in the appropriate `include` path using the `-I` option.

If a program uses data structures or classes that contain members with data types defined in the `omp.h` file, then source files that use those data structures should all be compiled with the same `omp.h` file.

Linux Examples

This section shows several examples of using OpenMP with the Intel C++ Compiler Classic from the command line on Linux.

Compile and Link OpenMP Libraries

You can compile an application and link the Intel OpenMP libraries with a single command using the `-qopenmp` option. For example:

```
icpc -qopenmp hello.cpp
```

By default, the Intel C++ Compiler Classic performs a dynamic link of the OpenMP libraries. To perform a static link (not recommended), add the option `-qopenmp-link=static`. The option `-qopenmp-link` controls whether the linker uses static or dynamic OpenMP libraries on Linux and macOS systems (default is `-qopenmp-link=dynamic`). See OpenMP Support Libraries for more information about dynamic and static OpenMP libraries.

Link OpenMP Object Files Compiled with GCC or Intel C++ Compiler Classic

You can use the `icc`/`icpc` compilers with the `gcc`/`g++` compilers to compile parts of an application and create object files that can then be linked (object-level interoperability).

When using `gcc` or the `g++` compiler to link the application with the Intel C++ Compiler Classic OpenMP compatibility library, you need to specify the following:

- The Intel OpenMP library name using the `-l` option
- The Linux `pthread` library using the `-l` option
- The path to the Intel libraries where the Intel C++ Compiler Classic is installed using the `-L` option

For example:

1. Compile `foo.c` and `bar.c` with `gcc`, using the `-fopenmp` option to enable OpenMP support:

```
gcc -fopenmp -c foo.c bar.c
```

   The `-c` prevents linking at this step.
2. Use the `gcc` compiler to link the application object code with the Intel OpenMP library:

```
gcc foo.o bar.o -liomp5 -lpthread -L<install_dir>/lib
```

   where <install_dir> is the location of the installed Intel OpenMP library.

Alternately, you can use the Intel C++ Compiler Classic to link the application so that you don't need to specify the `gcc-l` option, `-L` option, and the `-lpthread` options.

For example:

1. Compile `foo.c` with `gcc`, using the `gcc -fopenmp` option to enable OpenMP:

```
gcc -fopenmp -c foo.c
```

2. Compile `bar.c` with icc, using the `-qopenmp` option to enable OpenMP:

```
icc -qopenmp -c bar.c
```

3. Use the icc compiler to link the resulting application object code with the Intel OpenMP library:

```
icc -qopenmp foo.o bar.o
```

Link Mixed C/C++ and Fortran Object Files

You can mix C/C++ and Fortran object files and link the Intel OpenMP libraries using GNU, GCC, or Intel C++ Compiler Classic compilers.

This example shows mixed C and Fortran sources, linked using the Intel C++ Compiler Classic. Consider the mixed source files `ibar.c`, `gbar.c`, and `foo.f`, where the main program is contained in ibar.c:

1. Compile `ibar.c` using the icc compiler:

```
icc -qopenmp -c ibar.c
```

2. Compile `gbar.c` using the `gcc` compiler:

```
gcc -fopenmp -c gbar.c
```

3. Compile `foo.f` using the `ifort` compiler:

```
ifort -qopenmp -c foo.f
```

4. Use the icc compiler to link the resulting object files:

```
icc -qopenmp foo.o ibar.o gbar.o
```

If the main program were contained in the Fortran file foo.f, the linking step must be performed by the ifort compiler.

> **NOTE**
> Do not mix objects created by the Intel Fortran Compiler Classic and Intel Fortran Compiler with the GNU Fortran Compiler (`gfortran`); instead, recompile all Fortran sources with either `ifort` or `ifx`, or recompile all Fortran sources with the GNU Fortran Compiler . The GNU Fortran Compiler is only available on Linux operating systems.

When using the GNU `gfortran` Compiler to link the application with the Intel C++ Compiler Classic OpenMP compatibility library, you need to specify the following:

- The Intel® OpenMP compatibility library name and the Intel®`irc` libraries using the `-l` option
- The Linux `pthread` library using the `-l` option
- The path to the Intel® libraries where the Intel C++ Compiler Classic Classic is installed using the `-L` option

You do not need to specify the `-fopenmp` option on the link line.

For example, consider the mixed source files `ibar.c`, `gbar.c`, and `foo.f`:

1. Compile `ibar.c` using the icc compiler:

```
icc -qopenmp -c ibar.c
```

2. Compile `gbar.c` using the GCC compiler:

```
gcc -fopenmp -c gbar.c
```

3. Compile `foo.f` using the `gfortran` compiler:

```
gfortran -fopenmp -c foo.f
```

4. Use the `gfortran` compiler to link the application object code with the Intel OpenMP library. You do not need to specify the `-fopenmp` option in the link command:

```
gfortran foo.o ibar.o gbar.o -lirc -liomp5 -lpthread -lc -L<install_dir>/lib
```

where <install_dir> is the location of the installed Intel OpenMP library.

Alternately, you can use the Intel C++ Compiler Classic . to link the application object code but need to pass multiple `gfortran` libraries using the `-l` options at the link step.

This example shows mixed C and GNU Fortran sources linked using the icc compiler. Consider the mixed source files `ibar.c` and `foo.f`:

1. Compile the C source with the icc compiler:

```
icc -qopenmp -c ibar.c
```

2. Compile the GNU Fortran source with `gfortran`:

```
gfortran -fopenmp -c foo.f
```

3. Use icc to link the resulting object files with the `-l` option to pass the needed `gfortran` libraries:

```
icc -qopenmp foo.o ibar.o -lgfortran
```

macOS Examples

This section shows several examples of using OpenMP with the Intel C++ Compiler Classic from the command line on macOS.

Compile and Link OpenMP Libraries

You can compile an application and link the Intel OpenMP libraries with a single command using the `-qopenmp` option. For example:

```
icpc -qopenmp hello.cpp
```

By default, the the Intel C++ Compiler Classic performs a dynamic link of the OpenMP libraries. To perform a static link (not recommended), add the option `-qopenmp-link=static`. The option `-qopenmp-link` controls whether the linker uses static or dynamic OpenMP libraries on Linux and macOS systems (default is `-qopenmp-link=dynamic`).

Link Mixed OpenMP Object Files

You can mix OpenMP object files compiled by the Intel C++ Compiler Classic and Intel Fortran Compiler Classic.

This example shows mixed C and Fortran sources, compiled by the `icc` and `ifort` drivers, linked using the the Intel C++ Compiler Classic . Consider the mixed source files `ibar.c` and `foo.f90`:

1. Compile `ibar.c` using `icc`:

```
icc -qopenmp -c ibar.c
```

   The -c prevents linking at this step.

2. Compile `foo.f90` using `ifort`:

```
ifort -qopenmp -c foo.f90
```

3. Use `icc` to link the resulting object files:

```
icc -qopenmp foo.o ibar.o
```

Windows Examples

This section shows several examples of using OpenMP with the Intel C++ Compiler Classic from the command line on Windows.

Compile and Link OpenMP Libraries

You can compile an application and link the Compatibility libraries with a single command using the `/Qopenmp` option. By default, the Intel C++ Compiler Classic performs a dynamic link of the OpenMP libraries.

For example, to compile source file `hello.cpp` and link Compatibility libraries using the Intel C++ Compiler Classic:

```
icl /MD /Qopenmp hello.cpp
```

When using the Microsoft Visual C++ Compiler, you should link with the Intel® OpenMP compatibility library. You need to avoid linking the Microsoft OpenMP runtime library (`vcomp`) and explicitly pass the name of the Intel® OpenMP compatibility library as linker options using the `/link` option. For example:

```
cl /MD /openmp hello.cpp /link /nodefaultlib:vcomp libiomp5md.lib
```

Mix OpenMP Object Files Compiled with Visual C++ Compiler or Intel C++ Compiler Classic

You can use the Intel C++ Compiler Classic with the Visual C++ Compiler to compile parts of an application and create object files that can then be linked (object-level interoperability).

For example:

1. Compile `f1.c` and `f2.c` with the Visual C++ Compiler, using the `/openmp` option to enable OpenMP support:

```
cl /MD /openmp /c f1.c f2.c
```

   The `/c` prevents linking at this step.
2. Compile `f3.c` and `f4.c` with the icl compiler, using the `/Qopenmp` option to enable OpenMP support:

```
icl /MD /Qopenmp /c f3.c f4.c
```

3. Use the icl compiler to link the resulting application object code with the Intel C++ Compiler OpenMP library:

```
icl /MD /Qopenmp f1.obj f2.obj f3.obj f4.obj /Feapp /link /nodefaultlib:vcomp
```

   The `/Fe` specifies the generated executable file name.

   Alternatively, use the Visual C++ linker to link the application object code with the Compatibility library `libiomp5md.lib`:

```
link f1.obj f2.obj f3.obj f4.obj /out:app.exe /nodefaultlib:vcomp libiomp5md.lib
```

Use Intel OpenMP Libraries from Visual Studio

When running Windows, you can make certain changes in the Visual C++ Visual Studio development environment to use the Intel C++ Compiler Classic and Visual C++ to create applications that use the Intel OpenMP libraries.

Set the project **Property Pages** to indicate the Intel OpenMP runtime library location:

1. Open the project's property pages in from the main menu: **Project** > **Properties** (or right-click the Project name and select **Properties**) .
2. Select **Configuration Properties** > **Linker** > **General** > **Additional Library Directories**.
3. Enter the path to the Intel®-provided compiler libraries. For example, for an IA-32 architecture system (C/C++ only), enter:

```
<Intel_compiler_installation_path>\windows\compiler\lib\ia32 win
```

Make the Intel OpenMP dynamic runtime library accessible at runtime; you must specify the corresponding path:

1. Open the project's property pages in from the main menu: **Project** > **Properties** (or right-click the Project name and select **Properties**).
2. Select **Configuration Properties** > **Debugging** > **Environment**.

3. Enter the path to the Intel®-provided compiler libraries. For example, for an IA-32 architecture system (C/C++ only), enter:

```
PATH=%PATH%;<Intel_compiler_installation_path>\windows\redist\ia32_win\compiler
```

Add the Intel OpenMP runtime library name to the linker options and exclude the default Microsoft OpenMP runtime library:

1. Open the project's property pages in from the main menu: **Project** > **Properties** (or right-click the Project name and select **Properties**).
2. Select **Configuration Properties** > **Linker** > **Command Line** > **Additional Options**.
3. Enter the OpenMP library name and the Visual C++ linker option, `/nodefaultlib:vcomp libiomp5md.lib`.

Thread Affinity Interface

The Intel® runtime library has the ability to bind OpenMP* threads to physical processing units. The interface is controlled using the `KMP_AFFINITY` environment variable. Depending on the system (machine) topology, application, and operating system, thread affinity can have a dramatic effect on the application speed.

Thread affinity restricts execution of certain threads (virtual execution units) to a subset of the physical processing units in a multiprocessor computer. Depending upon the topology of the machine, thread affinity can have a dramatic effect on the execution speed of a program.

Thread affinity is supported on Windows* systems and versions of Linux* systems that have kernel support for thread affinity, but is not supported by macOS.

The Intel OpenMP runtime library has the ability to bind OpenMP threads to physical processing units. There are three types of interfaces you can use to specify this binding, which are collectively referred to as the Intel OpenMP Thread Affinity Interface:

- The high-level affinity interface uses an environment variable to determine the machine topology and assigns OpenMP threads to the processors based upon their physical location in the machine. This interface is controlled entirely by the `KMP_AFFINITY` environment variable.
- The mid-level affinity interface uses an environment variable to explicitly specifies which processors (labeled with integer IDs) are bound to OpenMP threads. This interface provides compatibility with the GCC* `GOMP_AFFINITY` environment variable, but you can also invoke it by using the `KMP_AFFINITY` environment variable. The `GOMP_AFFINITY` environment variable is supported on Linux systems only, but users on Windows or Linux systems can use the similar functionality provided by the `KMP_AFFINITY` environment variable.
- The low-level affinity interface uses APIs to enable OpenMP threads to make calls into the OpenMP runtime library to explicitly specify the set of processors on which they are to be run. This interface is similar in nature to `sched_setaffinity` and related functions on Linux systems or to `SetThreadAffinityMask` and related functions on Windows systems. In addition, you can specify certain options of the `KMP_AFFINITY` environment variable to affect the behavior of the low-level API interface. For example, you can set the affinity type `KMP_AFFINITY` to disabled, which disables the low-level affinity interface, or you could use the `KMP_AFFINITY` or `GOMP_AFFINITY` environment variables to set the initial affinity mask, and then retrieve the mask with the low-level API interface.

The following terms are used in this section:

- The total number of processing elements on the machine is referred to as the number of *OS thread contexts.*
- Each processing element is referred to as an Operating System processor, or *OS proc*.
- Each OS processor has a unique integer identifier associated with it, called an *OS proc ID*.

- The term *package* refers to a single or multi-core processor chip.
- The term *OpenMP Global Thread ID* (GTID) refers to an integer which uniquely identifies all threads known to the Intel OpenMP runtime library. The thread that first initializes the library is given GTID 0. In the normal case where all other threads are created by the library and when there is no nested parallelism, then *n-threads-var* - 1 new threads are created with GTIDs ranging from 1 to *ntheads-var* - 1, and each thread's GTID is equal to the OpenMP thread number returned by function `omp_get_thread_num()`. The high-level and mid-level interfaces rely heavily on this concept. Hence, their usefulness is limited in programs containing nested parallelism. The low-level interface does not make use of the concept of a GTID and can be used by programs containing arbitrarily many levels of parallelism.

Some environment variables are available for both Intel® microprocessors and non-Intel microprocessors, but may perform additional optimizations for Intel® microprocessors than for non-Intel microprocessors.

The KMP_AFFINITY Environment Variable

NOTE
You must set the `KMP_AFFINITY` environment variable before the first parallel region, or certain API calls including `omp_get_max_threads()`, `omp_get_num_procs()` and any affinity API calls, as described in Low Level Affinity API, below.

The `KMP_AFFINITY` environment variable uses the following general syntax:

Syntax
KMP_AFFINITY=[<*modifier*>,...]<*type*>[,<*permute*>][,<*offset*>]

For example, to list a machine topology map, specify `KMP_AFFINITY=verbose,none` to use a *modifier* of `verbose` and a *type* of `none`.

The following table describes the supported specific arguments.

Argument	**Default**	**Description**

`modifier`	`noverbose`
	`respect`
	`granularity=core`
		Optional. String consisting of keyword and specifier.
		• `granularity=<specifier>` takes the following specifiers: fine, thread, core, tile, die, node, group, and socket
		• `norespect`
		• `noverbose`
		• `nowarnings`
		• `noreset`
		• `proclist={<proc-list>}`
		• `respect`
		• `verbose`
		• `warnings`
		• `reset`
		The syntax for `<proc-list>` is explained in mid-level affinity interface.

Argument	Default	Description
		NOTE On Windows with multiple processor groups, the norespect affinity modifier is assumed when the process affinity mask equals a single processor group (which is default on Windows). Otherwise, the respect affinity modifier is used.
`type`	`none`	Required string. Indicates the thread affinity to use. • `balanced` • `compact` • `disabled` • `explicit` • `none` • `scatter` • `logical` (deprecated; instead use `compact`, but omit any `permute value`) • `physical` (deprecated; instead use `scatter`, possibly with an `offset value`) The `logical` and `physical` types are deprecated but supported for backward compatibility.
`permute`	`0`	Optional. Positive integer value. Not valid with type values of `explicit`, `none`, or `disabled`.
`offset`	`0`	Optional. Positive integer value. Not valid with type values of `explicit`, `none`, or `disabled`.

Affinity Types

Type is the only required argument.

type = none (default)

Does not bind OpenMP threads to particular thread contexts; however, if the operating system supports affinity, the compiler still uses the OpenMP thread affinity interface to determine machine topology. Specify `KMP_AFFINITY=verbose,none` to list a machine topology map.

type = balanced

Places threads on separate cores until all cores have at least one thread, similar to the `scatter` type. However, when the runtime must use multiple hardware thread contexts on the same core, the `balanced` type ensures that the OpenMP thread numbers are close to each other, which `scatter` does not do. This affinity type is supported on the CPU only for single socket systems.

NOTE
The OpenMP* environment variable `OMP_PROC_BIND=spread` is similar to `KMP_AFFINITY=balanced` and is available on all platforms, including multi-socket CPU systems.

type = compact

Specifying `compact` assigns the OpenMP thread <*n*>+1 to a free thread context as close as possible to the thread context where the <*n*> OpenMP thread was placed. For example, in a topology map, the nearer a node is to the root, the more significance the node has when sorting the threads.

type = disabled

Specifying `disabled` completely disables the thread affinity interfaces. This forces the OpenMP run-time library to behave as if the affinity interface was not supported by the operating system. This includes the low-level API interfaces such as `kmp_set_affinity` and `kmp_get_affinity`, which have no effect and will return a nonzero error code.

type = explicit

Specifying `explicit` assigns OpenMP threads to a list of OS proc IDs that have been explicitly specified by using the proclist= modifier, which is required for this affinity type. See Explicitly Specifying OS Proc IDs (GOMP_CPU_AFFINITY).

type = scatter

Specifying `scatter` distributes the threads as evenly as possible across the entire system. `scatter` is the opposite of `compact`; so the leaves of the node are most significant when sorting through the machine topology map.

Deprecated Types: logical and physical

Types `logical` and `physical` are deprecated and may become unsupported in a future release. Both are supported for backward compatibility.

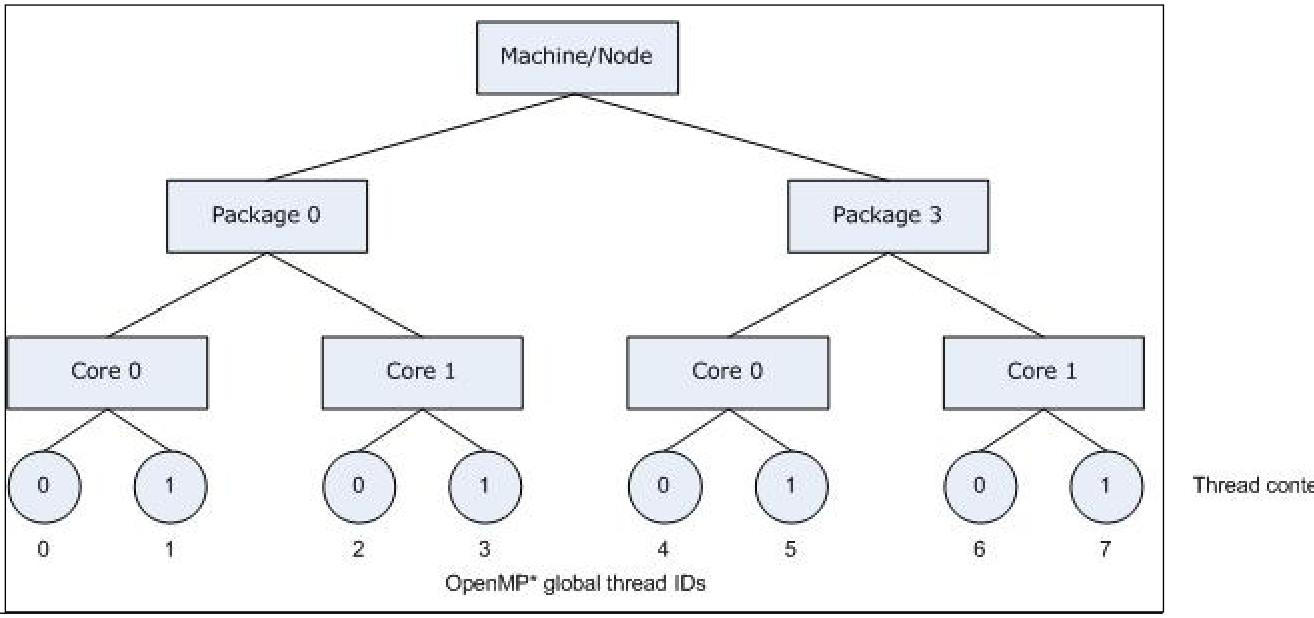
For `logical` and `physical` affinity types, a single trailing integer is interpreted as an `offset` specifier instead of a `permute` specifier. In contrast, with `compact` and `scatter` types, a single trailing integer is interpreted as a `permute` specifier.

- Specifying `logical` assigns OpenMP threads to consecutive logical processors, which are also called hardware thread contexts. The type is equivalent to `compact`, except that the `permute` specifier is not allowed. Thus, `KMP_AFFINITY=logical,n` is equivalent to `KMP_AFFINITY=compact,0,n` (this equivalence is true regardless of the whether or not a `granularity=fine` modifier is present).
- Specifying `physical` assigns threads to consecutive physical processors (cores). For systems where there is only a single thread context per core, the type is equivalent to `logical`. For systems where multiple thread contexts exist per core, `physical` is equivalent to `compact` with a `permute` specifier of 1; that is, `KMP_AFFINITY=physical,n` is equivalent to `KMP_AFFINITY=compact,1,n` (regardless of the whether or not a `granularity=fine` modifier is present). This equivalence means that when the compiler sorts the map it should permute the innermost level of the machine topology map to the outermost, presumably the thread context level. This type does not support the `permute` specifier.

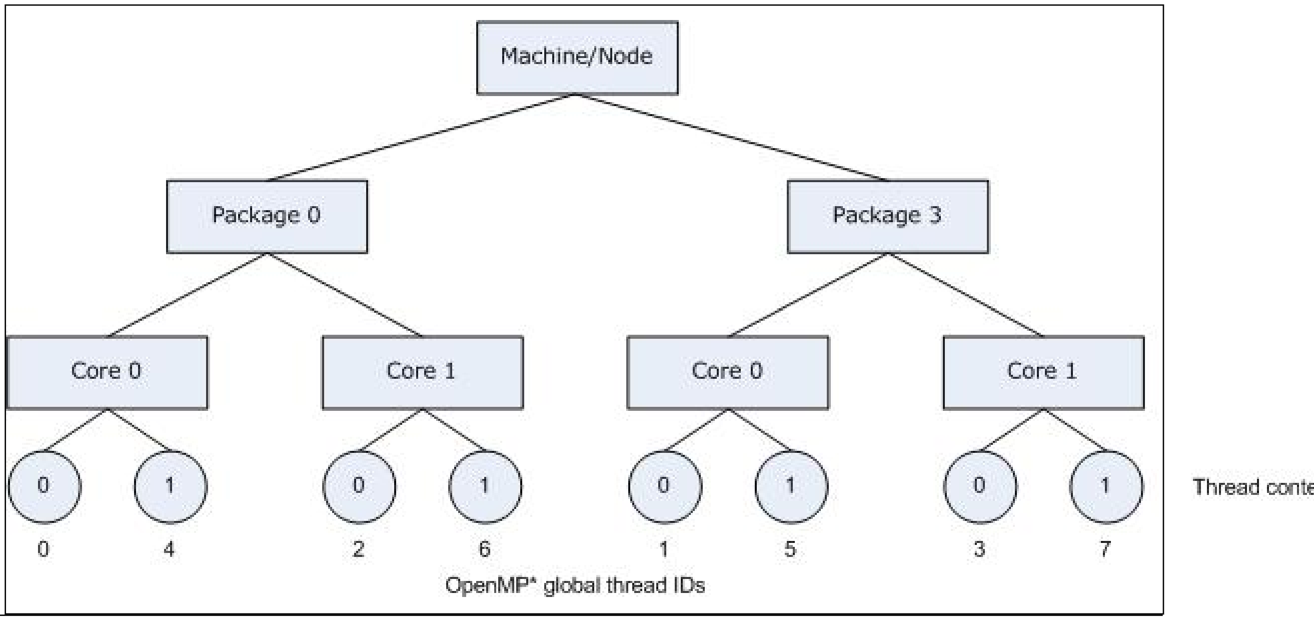
Examples of Types `compact` and `scatter`

The following figure illustrates the topology for a machine with two processors, and each processor has two cores; further, each core has Intel® Hyper-Threading Technology (Intel® HT Technology) enabled.

The following figure also illustrates the binding of OpenMP thread to hardware thread contexts when specifying `KMP_AFFINITY=granularity=fine,compact`.



Specifying `scatter` on the same system as shown in the figure above, the OpenMP threads would be assigned the thread contexts as shown in the following figure, which shows the result of specifying `KMP_AFFINITY=granularity=fine,scatter`.



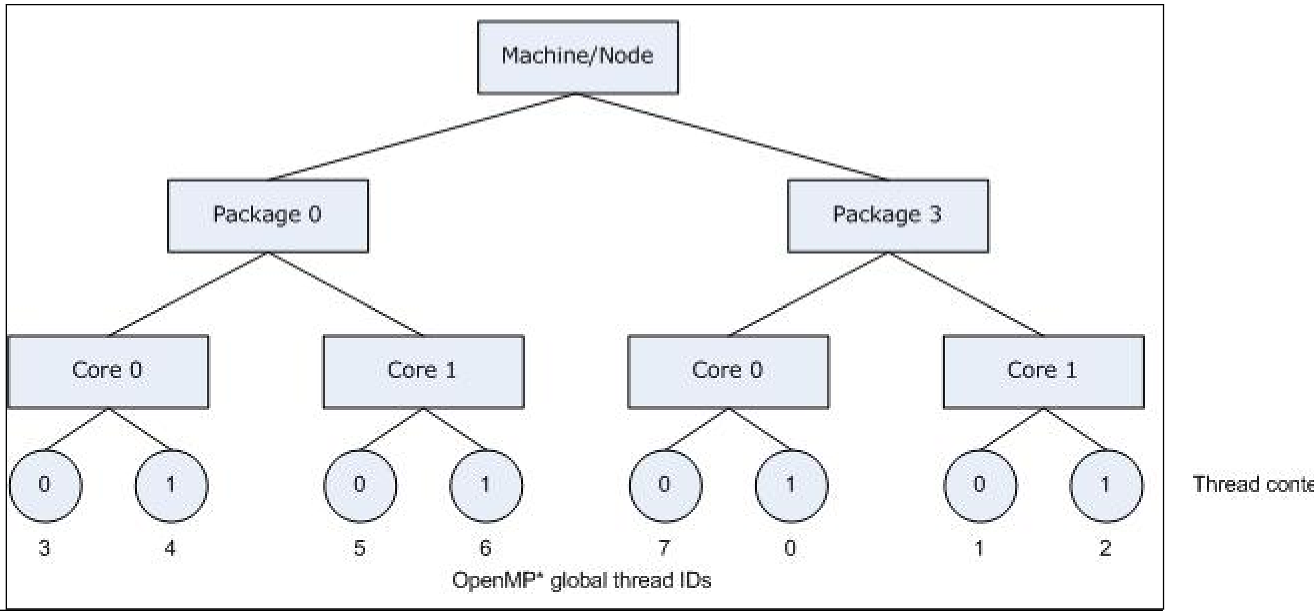
permute and offset combinations

For both `compact` and `scatter`, `permute` and `offset` are allowed; however, if you specify only one integer, the compiler interprets the value as a permute specifier. Both `permute` and `offset` default to 0.

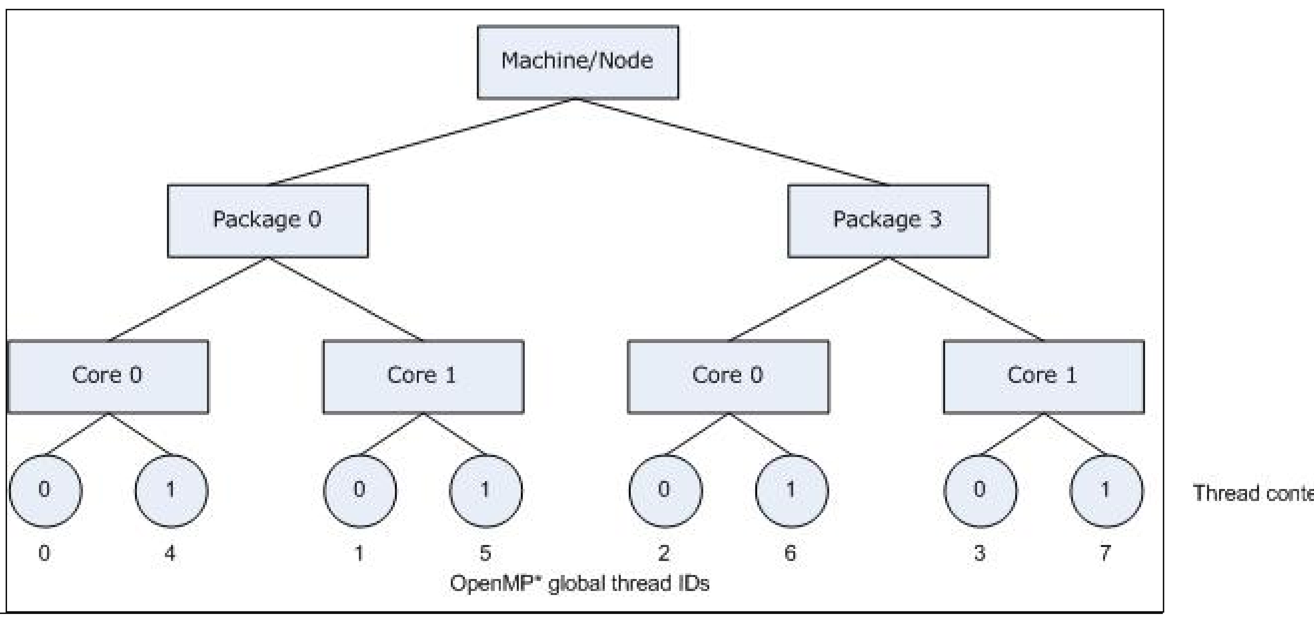
The `permute` specifier controls which levels are most significant when sorting the machine topology map. A value for permute forces the mappings to make the specified number of most significant levels of the sort the least significant, and it inverts the order of significance. The root node of the tree is not considered a separate level for the sort operations.

The `offset` specifier indicates the starting position for thread assignment.

The following figure illustrates the result of specifying `KMP_AFFINITY=granularity=fine,compact,0,5`.



Consider the hardware configuration from the previous example, running an OpenMP application which exhibits data sharing between consecutive iterations of loops. We would therefore like consecutive threads to be bound close together, as is done with `KMP_AFFINITY=compact`, so that communication overhead, cache line invalidation overhead, and page thrashing are minimized. Now, suppose the application also had a number of parallel regions which did not utilize all of the available OpenMP threads. It is desirable to avoid binding multiple threads to the same core and leaving other cores not utilized, since a thread normally executes faster on a core where it is not competing for resources with another active thread on the same core. Since a thread normally executes faster on a core where it is not competing for resources with another active thread on the same core, you might want to avoid binding multiple threads to the same core while leaving other cores unused. The following figure illustrates this strategy of using `KMP_AFFINITY=granularity=fine,compact,1,0` as a setting.



The OpenMP thread *n*+1 is bound to a thread context as close as possible to OpenMP thread *n*, but on a different core. Once each core has been assigned one OpenMP thread, the subsequent OpenMP threads are assigned to the available cores in the same order, but they are assigned on different thread contexts.

Modifier Values for Affinity Types

Modifiers are optional arguments that precede type. If you do not specify a modifier, the `noverbose`, `respect`, and `granularity=core` modifiers are used automatically.

Modifiers are interpreted in order from left to right, and they may conflict. Following conflicting modifier is ignored. For example, specifying `KMP_AFFINITY=verbose,noverbose,scatter` is therefore equivalent to setting `KMP_AFFINITY=verbose,scatter`.

modifier = noverbose (default)

Does not print verbose messages.

modifier = verbose

Prints messages concerning the supported affinity. The messages include information about the number of packages, number of cores in each package, number of thread contexts for each core, and OpenMP thread bindings to physical thread contexts.

Information about binding OpenMP threads to physical thread contexts is indirectly shown in the form of the mappings between hardware thread contexts and the operating system (OS) processor (proc) IDs. The affinity mask for each OpenMP thread is printed as a set of OS processor IDs.

For example, specifying `KMP_AFFINITY=verbose,scatter` on a dual core system with two processors, with Intel® Hyper-Threading Technology (Intel® HT Technology) disabled, results in a message listing similar to the following when then program is executed:

Verbose, scatter message

```
...
KMP_AFFINITY: Initial OS proc set respected: 0,1,2,3
KMP_AFFINITY: affinity capable, using hwloc.
KMP_AFFINITY: 4 available OS procs
KMP_AFFINITY: Uniform topology
KMP_AFFINITY: 2 sockets x 2 cores/socket x 1 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map:
KMP_AFFINITY: OS proc 0 maps to socket 0 core 0 thread 0
KMP_AFFINITY: OS proc 2 maps to socket 0 core 1 thread 0
KMP_AFFINITY: OS proc 1 maps to socket 3 core 0 thread 0
KMP_AFFINITY: OS proc 3 maps to socket 3 core 1 thread 0
KMP_AFFINITY: pid 79739 tid 79739 thread 0 bound to OS proc set 0
KMP_AFFINITY: pid 79739 tid 79740 thread 2 bound to OS proc set 2
KMP_AFFINITY: pid 79739 tid 79741 thread 3 bound to OS proc set 3
KMP_AFFINITY: pid 79739 tid 79742 thread 1 bound to OS proc set 1
```

The verbose modifier generates several standard, general messages. The following table summarizes how to read the messages.

Message String	Description
"affinity capable"	Indicates that all components (compiler, operating system, and hardware) support affinity, so thread binding is possible.
"decoding x2APIC ids"	Indicates that the machine topology was discovered by binding a thread to each operating system processor and decoding the output of the `cpuid` instruction.

Message String	Description
"using hwloc"	Indicates that the Portable Hardware Locality* (`hwloc`) library used to determine machine topology.
"using /proc/cpuinfo"	Linux only. Indicates that `cpuinfo` is being used to determine machine topology.
"using flat"	Operating system processor ID is assumed to be equivalent to physical package ID. This method of determining machine topology is used if none of the other methods will work, but may not accurately detect the actual machine topology.
"uniform topology"	The machine topology map is a full tree with no missing leaves at any level.

The mapping from the operating system processors to thread context ID is printed next. The binding of OpenMP thread context ID is printed next unless the affinity type is none. For more information, see Determining Machine Topology.

modifier = granularity

Binding OpenMP threads to particular packages and cores will often result in a performance gain on systems with Intel processors with Intel® Hyper-Threading Technology (Intel® HT Technology) enabled; however, it is usually not beneficial to bind each OpenMP thread to a particular thread context on a specific core. Granularity describes the lowest levels that OpenMP threads are allowed to float within a topology map.

This modifier supports the following additional specifiers.

Specifier	Description
`core`	Default. Allows all the OpenMP threads bound to a core to float between the different thread contexts.
`fine` or `thread`	The finest granularity level. Causes each OpenMP thread to be bound to a single thread context. The two specifiers are functionally equivalent.
`tile`, or `die`, or `node`, or `group`, or `socket`	Allows all the OpenMP threads bound to a tile, or die, or NUMA node, or group, or socket to float between the different thread contexts of cores the tile, or die, or NUMA node, or group, or socket consists of.

Specifying `KMP_AFFINITY=verbose,granularity=core,compact` on the same dual core system with two processors as in the previous section, but with Intel® Hyper-Threading Technology (Intel® HT Technology) enabled, results in a message listing similar to the following when the program is executed:

Verbose, granularity=core,compact message

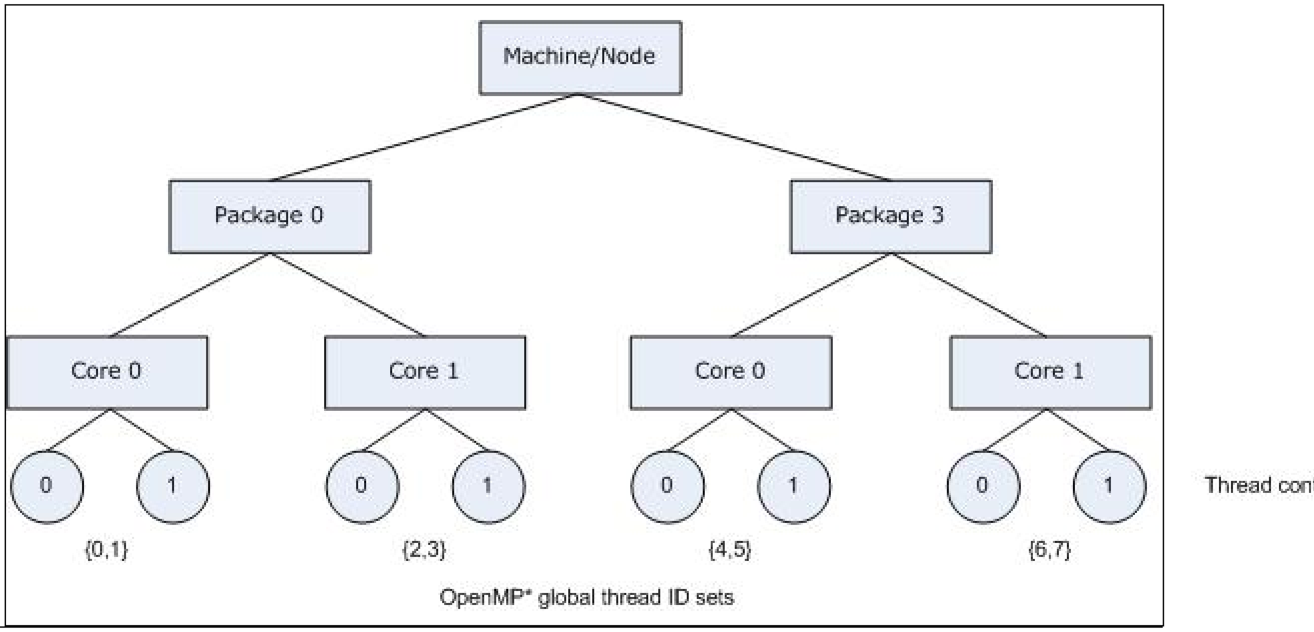
```
KMP_AFFINITY: Initial OS proc set respected: 0-7
KMP_AFFINITY: decoding x2APIC ids.
KMP_AFFINITY: 8 available OS procs
KMP_AFFINITY: Uniform topology
KMP_AFFINITY: 2 sockects x 2 cores/socket x 2 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map:
KMP_AFFINITY: OS proc 0 maps to socket 0 core 0 thread 0
KMP_AFFINITY: OS proc 4 maps to socket 0 core 0 thread 1
KMP_AFFINITY: OS proc 2 maps to socket 0 core 1 thread 0
KMP_AFFINITY: OS proc 6 maps to socket 0 core 1 thread 1
KMP_AFFINITY: OS proc 1 maps to socket 3 core 0 thread 0
KMP_AFFINITY: OS proc 5 maps to socket 3 core 0 thread 1
```

Verbose, granularity=core,compact message

```
KMP_AFFINITY: OS proc 3 maps to socket 3 core 1 thread 0
KMP_AFFINITY: OS proc 7 maps to socket 3 core 1 thread 1
KMP_AFFINITY: pid 40880 tid 40880 thread 0 bound to OS proc set 0,4
KMP_AFFINITY: pid 40880 tid 40881 thread 1 bound to OS proc set 0,4
KMP_AFFINITY: pid 40880 tid 40882 thread 2 bound to OS proc set 2,6
KMP_AFFINITY: pid 40880 tid 40883 thread 3 bound to OS proc set 2,6
KMP_AFFINITY: pid 40880 tid 40884 thread 4 bound to OS proc set 1,5
KMP_AFFINITY: pid 40880 tid 40885 thread 5 bound to OS proc set 1,5
KMP_AFFINITY: pid 40880 tid 40886 thread 6 bound to OS proc set 3,7
KMP_AFFINITY: pid 40880 tid 40887 thread 7 bound to OS proc set 3,7
```

The affinity mask for each OpenMP thread is shown in the listing (above) as the set of operating system processor to which the OpenMP thread is bound.

The following figure illustrates the machine topology map, for the above listing, with OpenMP thread bindings.



In contrast, specifying `KMP_AFFINITY=verbose,granularity=fine,compact` or `KMP_AFFINITY=verbose,granularity=thread,compact` binds each OpenMP thread to a single hardware thread context when the program is executed:

Verbose, granularity=fine,compact message

```
KMP_AFFINITY: Initial OS proc set respected: 0-7
KMP_AFFINITY: decoding x2APIC ids.
KMP_AFFINITY: 8 available OS procs
KMP_AFFINITY: Uniform topology
KMP_AFFINITY: 2 sockets x 2 cores/socket x 2 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map:
KMP_AFFINITY: OS proc 0 maps to socket 0 core 0 thread 0
KMP_AFFINITY: OS proc 4 maps to socket 0 core 0 thread 1
KMP_AFFINITY: OS proc 2 maps to socket 0 core 1 thread 0
KMP_AFFINITY: OS proc 6 maps to socket 0 core 1 thread 1
KMP_AFFINITY: OS proc 1 maps to socket 3 core 0 thread 0
```

Verbose, granularity=fine,compact message

```
KMP_AFFINITY: OS proc 5 maps to socket 3 core 0 thread 1
KMP_AFFINITY: OS proc 3 maps to socket 3 core 1 thread 0
KMP_AFFINITY: OS proc 7 maps to socket 3 core 1 thread 1
KMP_AFFINITY: pid 40895 tid 40895 thread 0 bound to OS proc set 0
KMP_AFFINITY: pid 40895 tid 40896 thread 1 bound to OS proc set 4
KMP_AFFINITY: pid 40895 tid 40897 thread 2 bound to OS proc set 2
KMP_AFFINITY: pid 40895 tid 40898 thread 3 bound to OS proc set 6
KMP_AFFINITY: pid 40895 tid 40899 thread 4 bound to OS proc set 1
KMP_AFFINITY: pid 40895 tid 40900 thread 5 bound to OS proc set 5
KMP_AFFINITY: pid 40895 tid 40901 thread 6 bound to OS proc set 3
KMP_AFFINITY: pid 40895 tid 40902 thread 7 bound to OS proc set 7
```

The OpenMP to hardware context binding for this example was illustrated in the first example.

Specifying `granularity=fine` will always cause each OpenMP thread to be bound to a single OS processor. This is equivalent to `granularity=thread`, currently the finest granularity level.

modifier = respect (default)

Respect the process' original affinity mask, or more specifically, the affinity mask in place for the thread that initializes the OpenMP run-time library. The behavior differs between Linux and Windows:

- On Windows: Respect original affinity mask for the process.
- On Linux: Respect the affinity mask for the thread that initializes the OpenMP run-time library.

> **NOTE** On Windows with multiple processor groups, the `norespect` affinity modifier is the default when the process affinity mask equals a single processor group (which is default on Windows). Otherwise, the respect affinity modifier is the default.

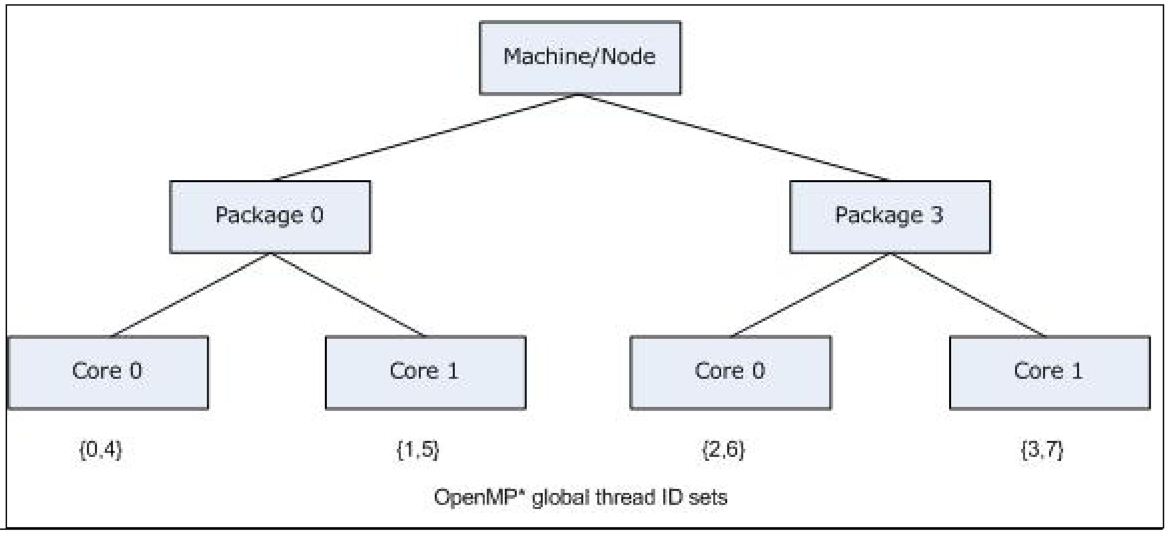
Specifying `KMP_AFFINITY=verbose,compact` for the same system used in the previous example, with Intel® Hyper-Threading Technology (Intel® HT Technology) enabled, and invoking the library with an initial affinity mask of {4,5,6,7} (thread context 1 on every core) causes the compiler to model the machine as a dual core, two-processor system with Intel® HT Technology disabled.

Verbose,compact message

```
KMP_AFFINITY: Initial OS proc set respected: 4-7
KMP_AFFINITY: decoding x2APIC ids.
KMP_AFFINITY: 4 available OS procs
KMP_AFFINITY: Uniform topology
KMP_AFFINITY: 2 sockets x 2 cores/socket x 1 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map:
KMP_AFFINITY: OS proc 4 maps to socket 0 core 0 thread 1
KMP_AFFINITY: OS proc 6 maps to socket 0 core 1 thread 1
KMP_AFFINITY: OS proc 5 maps to socket 3 core 0 thread 1
KMP_AFFINITY: OS proc 7 maps to socket 3 core 1 thread 1
KMP_AFFINITY: pid 41032 tid 41032 thread 0 bound to OS proc set 4
KMP_AFFINITY: pid 41032 tid 41033 thread 1 bound to OS proc set 6
KMP_AFFINITY: pid 41032 tid 41034 thread 2 bound to OS proc set 5
KMP_AFFINITY: pid 41032 tid 41035 thread 3 bound to OS proc set 7
```

Because there are four thread contexts accessible on the machine, by default the compiler created four threads for an OpenMP `parallel` construct.

The following figure illustrates the corresponding machine topology map and threads placement in case eight OpenMP threads requested via `OMP_NUM_THREADS=8`



When using the local `cpuid` information to determine the machine topology, it is not always possible to distinguish between a machine that does not support Intel® Hyper-Threading Technology (Intel® HT Technology) and a machine that supports it, but has it disabled. Therefore, the compiler does not include a level in the map if the elements (nodes) at that level had no siblings, with the exception that the package level is always modeled. As mentioned earlier, the package level will always appear in the topology map, even if there only a single package in the machine.

modifier = norespect

Do not respect original affinity mask for the process. Binds OpenMP threads to all operating system processors.

In early versions of the OpenMP run-time library that supported only the `physical` and `logical` affinity types, `norespect` was the default and was not recognized as a modifier.

The default was changed to respect when types `compact` and `scatter` were added; therefore, thread bindings may have changed with the newer compilers in situations where the application specified a partial initial thread affinity mask.

modifier = nowarnings

Do not print warning messages from the affinity interface.

modifier = warnings (default)

Print warning messages from the affinity interface (default).

modifier = noreset (default)

Do not reset the primary thread's affinity after each outermost parallel region is complete. This setting preserves the primary thread's OpenMP affinity setting between parallel regions. For example, if `KMP_AFFINITY=compact,granularity=core`, then the primary thread's affinity is set to the first core for the first parallel region and kept that way for the thread's lifetime, even during serial regions.

modifier = reset

Reset the primary thread's affinity after each outermost parallel region is complete. This setting will reset the primary thread's affinity back to the initial affinity before OpenMP was initialized after each outermost parallel region is complete.

Determining Machine Topology

On IA-32 and Intel® 64 architecture systems, if the package has an APIC (Advanced Programmable Interrupt Controller), the compiler will use the `cpuid` instruction to obtain the `package id`, `core id`, and `thread context id`. Under normal conditions, each thread context on the system is assigned a unique APIC ID at boot time. The compiler obtains other pieces of information obtained by using the *cpuid* instruction, which together with the number of OS thread contexts (total number of processing elements on the machine), determine how to break the APIC ID down into the `package ID`, `core ID`, and `thread context ID`.

There are several ways to specify the APIC ID in the *cpuid* instruction - the legacy method in leaf 4, and the more modern method in leaf 11 and leaf 31. Only 256 unique APIC IDs are available in leaf 4. Leaf 11 and leaf 31 have no such limitation.

Normally, all `core ids` on a package and all `thread context ids` on a core are contiguous; however, numbering assignment gaps are common for `package ids`, as shown in the figure above.

If the compiler cannot determine the machine topology using any other method, but the operating system supports affinity, a warning message is printed, and the topology is assumed to be `flat`. For example, a flat topology assumes the operating system process *N* maps to package *N*, and there exists only one thread context per core and only one core for each package.

If the machine topology cannot be accurately determined as described above, the user can manually copy `/proc/cpuinfo` to a temporary file, correct any errors, and specify the machine topology to the OpenMP runtime library via the environment variable `KMP_CPUINFO_FILE=<temp_filename>`, as described in the section `KMP_CPUINFO_FILE` and `/proc/cpuinfo`.

Regardless of the method used in determining the machine topology, if there is only one thread context per core for every core on the machine, the thread context level will not appear in the topology map. If there is only one core per package for every package in the machine, the core level will not appear in the machine topology map. The topology map need not be a full tree, because different packages may contain a different number of cores, and different cores may support a different number of thread contexts.

The package level will always appear in the topology map, even if there only a single package in the machine.

KMP_CPUINFO_FILE and /proc/cpuinfo

One of the methods the Intel® C++ Compiler Classic OpenMP runtime library can use to detect the machine topology on Linux systems is to parse the contents of `/proc/cpuinfo`. If the contents of this file (or a device mapped into the Linux file system) are insufficient or erroneous, you can consider copying its contents to a writable temporary file `<temp_file>`, correct it or extend it with the necessary information, and set `KMP_CPUINFO_FILE=<temp_file>`.

If you do this, the OpenMP runtime library will read the `<temp_file>` location pointed to by `KMP_CPUINFO_FILE` instead of the information contained in `/proc/cpuinfo` or attempting to detect the machine topology by decoding the APIC IDs. That is, the information contained in the <*temp_file*> overrides these other methods. You can use the KMP_CPUINFO_FILE interface on Windows systems, where `/proc/cpuinfo` does not exist.

The content of `/proc/cpuinfo` or `<temp_file>` should contain a list of entries for each processing element on the machine. Each processor element contains a list of entries (descriptive name and value on each line). A blank line separates the entries for each processor element. Only the following fields are used to determine the machine topology from each entry, either in <*temp_file*> or `/proc/cpuinfo`:

Field	Description
processor :	Specifies the OS ID for the processing element. The OS ID must be unique. The `processor` and `physical id` fields are the only ones that are required to use the interface.
physical id :	Specifies the package ID, which is a physical chip ID. Each package may contain multiple cores. The package level always exists in the compiler's OpenMP run-time library model of the machine topology.
core id :	Specifies the core ID. If it does not exist, it defaults to 0. If every package on the machine contains only a single core, the core level will not exist in the machine topology map (even if some of the core ID fields are non-zero).
apicid :	Specifies the thread ID. If it does not exist, it defaults to 0. If every core on the machine contains only a single thread, the thread level will not exist in the machine topology map (even if some thread ID fields are non-zero).
node_*n* id :	This is a extension to the normal contents of `/proc/cpuinfo` that can be used to specify the nodes at different levels of the memory interconnect on Non-Uniform Memory Access (NUMA) systems. Arbitrarily many levels *n* are supported. The node_0 level is closest to the package level; multiple packages comprise a node at level 0. Multiple nodes at level 0 comprise a node at level 1, and so on.

Each entry must be spelled exactly as shown, in lowercase, followed by optional whitespace, a colon (:), more optional whitespace, then the integer ID. Fields other than those listed are simply ignored.

NOTE
It is common for the `thread id` field to be missing from `/proc/cpuinfo` on many Linux variants, and for a field labeled `siblings` to specify the number of threads per node or number of nodes per package. However, the Intel OpenMP runtime library ignores fields labeled `siblings` so it can distinguish between the `thread id` and `siblings` fields. When this situation arises, the warning message `Physical node/pkg/core/thread ids not unique` appears (unless the `type specified is nowarnings`).

Windows Processor Groups

On a 64-bit Windows operating system, it is possible for multiple processor groups to accommodate more than 64 processors. Each group is limited in size, up to a maximum value of sixty-four (64) processors.

If multiple processor groups are detected, the default is to model the machine as a 2-level tree, where level 0 are for the processors in a group, and level 1 are for the different groups. Threads are assigned to a group until there are as many OpenMP threads bound to the groups as there are processors in the group. Subsequent threads are assigned to the next group, and so on.

By default, threads are allowed to float among all processors in a group, that is to say, granularity equals the group [granularity=group]. You can override this binding and explicitly use another affinity type like compact, scatter, and so on. If you do so, the granularity must be sufficiently fine to prevent a thread from being bound to multiple processors in different groups.

Using a Specific Machine Topology Modeling Method (KMP_TOPOLOGY_METHOD)

You can set the `KMP_TOPOLOGY_METHOD` environment variable to force OpenMP to use a particular machine topology modeling method.

Value	Description
`cpuid_leaf11`	Decodes the APIC identifiers as specified by leaf 11 of the *cpuid* instruction.
`cpuid_leaf4`	Decodes the APIC identifiers as specified in leaf 4 of the *cpuid* instruction.
`cpuinfo`	If `KMP_CPUINFO_FILE` is not specified, forces OpenMP to parse `/proc/cpuinfo` to determine the topology (Linux only). If `KMP_CPUINFO_FILE` is specified as described above, uses it (Windows or Linux).
`group`	Models the machine as a 2-level map, with level 0 specifying the different processors in a group, and level 1 specifying the different groups (Windows 64-bit only) .
`flat`	Models the machine as a flat (linear) list of processors.
`hwloc`	Models the machine as the Portable Hardware Locality* (hwloc) library does. This model is the most detailed and includes, but is not limited to: numa nodes, packages, cores, hardware threads, caches, and Windows processor groups.

Explicitly Specifying OS Processor IDs (GOMP_CPU_AFFINITY)

NOTE
You must set the `GOMP_CPU_AFFINITY` environment variable before the first parallel region, or certain API calls including `omp_get_max_threads()`, `omp_get_num_procs()` and any affinity API calls, as described in Low Level Affinity API, below.

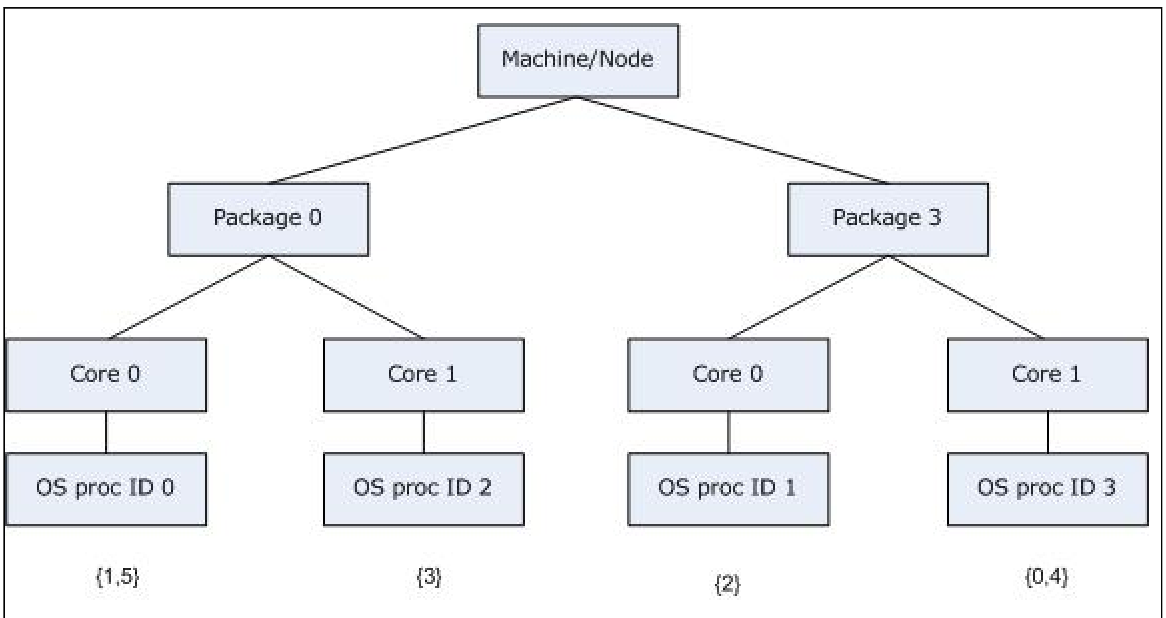
Instead of allowing the library to detect the hardware topology and automatically assign OpenMP threads to processing elements, the user may explicitly specify the assignment by using a list of operating system (OS) processor (proc) IDs. However, this requires knowledge of which processing elements the OS proc IDs represent.

On Linux systems, when using the Intel OpenMP compatibility libraries enabled by the compiler option `-qopenmp-lib compat`, you can use the `GOMP_AFFINITY` environment variable to specify a list of OS processor IDs. Its syntax is identical to that accepted by `libgomp` (assume that *<proc_list>* produces the entire `GOMP_AFFINITY` environment string):

Value	**Description**
<proc_list> :=	<entry> | *<elem>* , <list> | <elem> <whitespace> <list>
<elem> :=	*<proc_spec>* | *<range>*
<proc_spec> :=	*<proc_id>*
<range> :=	*<proc_id>* - *<proc_id>* | *<proc_id>* - *<proc_id>* : <int>
<proc_id> :=	<positive_int>

OS processors specified in this list are then assigned to OpenMP threads, in order of OpenMP Global Thread IDs. If more OpenMP threads are created than there are elements in the list, then the assignment occurs modulo the size of the list. That is, OpenMP Global Thread ID *n* is bound to list element *n* mod *<list_size>*.

Consider the machine previously mentioned: a dual core, dual-package machine without Intel® Hyper-Threading Technology (Intel® HT Technology) enabled, where the OS proc IDs are assigned in the same manner as the example in a previous figure. Suppose that the application creates six OpenMP threads instead of 4 (the default), oversubscribing the machine. If `GOMP_AFFINITY=3,0-2`, then OpenMP threads are bound as shown in the figure below, just as should happen when compiling with `gcc` and linking with `libgomp`:



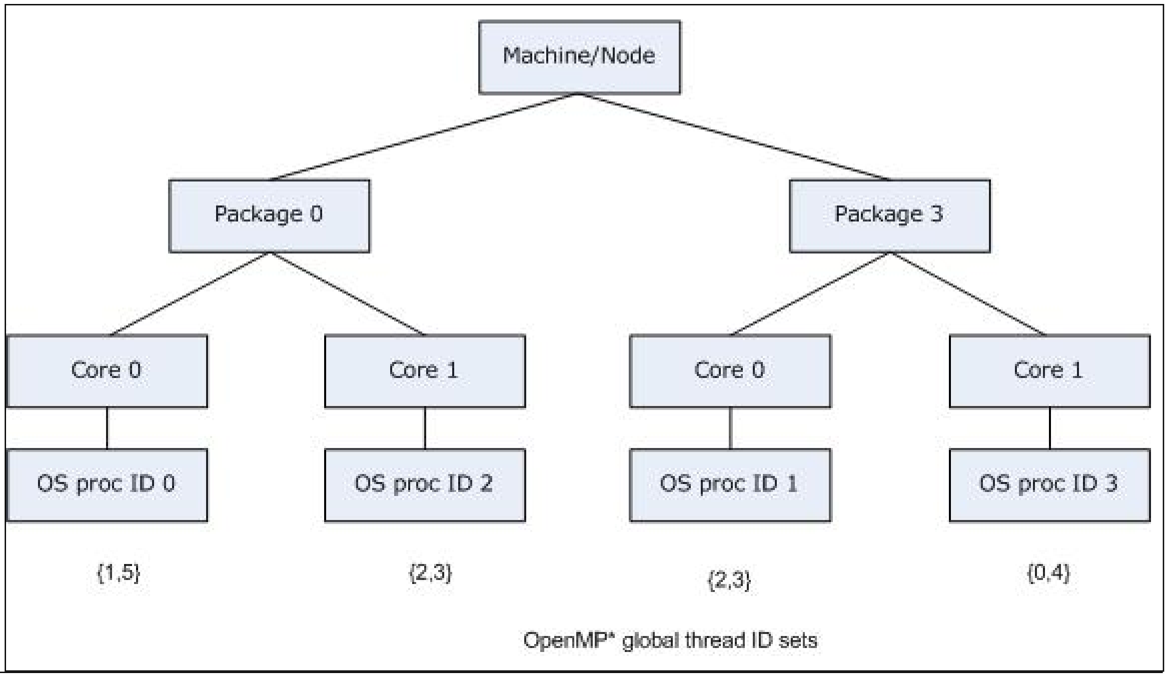
OpenMP* global thread ID sets

The same syntax can be used to specify the OS proc ID list in the proclist=[<proc_list>] modifier in the `KMP_AFFINITY` environment variable string. There is a slight difference: in order to have strictly the same semantics as in the `gcc` OpenMP runtime library `libgomp`: the `GOMP_AFFINITY` environment variable implies `granularity=fine`. If you specify the OS proc list in the `KMP_AFFINITY` environment variable without a `granularity=` specifier, then the default `granularity` is not changed. That is, OpenMP threads are allowed to float between the different thread contexts on a single core. Thus `GOMP_AFFINITY=<proc_list>` is an alias for `KMP_AFFINITY="granularity=fine,proclist=[<proc_list>],explicit"`.

In the `KMP_AFFINITY` environment variable string, the syntax is extended to handle operating system processor ID sets. The user may specify a set of operating system processor IDs among which an OpenMP thread may execute ("float") enclosed in brackets:

Value	Description
<proc_list> :=	<proc_id> | { <float_list> }
<float_list> :=	<proc_id> | <proc_id> , <float_list>

This allows functionality similarity to the `granularity= specifier`, but it is more flexible. The OS processors on which an OpenMP thread executes may exclude other OS processors nearby in the machine topology, but include other distant OS processors. Building upon the previous example, we may allow OpenMP threads 2 and 3 to "float" between OS processor 1 and OS processor 2 by using `KMP_AFFINITY="granularity=verbose,fine,proclist=[3,0,{1,2},{1,2}],explicit"`, as shown in the figure below:



If `verbose` were also specified, the output when the application is executed would include:

KMP_AFFINITY="granularity=verbose,fine,proclist=[3,0,{1,2},{1,2}],explicit"

```
KMP_AFFINITY: Initial OS proc set respected: 0,1,2,3
KMP_AFFINITY: decoding x2APIC ids.
KMP_AFFINITY: 4 available OS procs
KMP_AFFINITY: Uniform topology
KMP_AFFINITY: 2 sockets x 2 cores/socket x 1 threads/core (4 total cores)
KMP_AFFINITY: OS proc to physical thread map:
KMP_AFFINITY: OS proc 0 maps to socket 0 core 0 thread 0
KMP_AFFINITY: OS proc 2 maps to socket 0 core 1 thread 0
KMP_AFFINITY: OS proc 1 maps to socket 3 core 0 thread 0
KMP_AFFINITY: OS proc 3 maps to socket 3 core 1 thread 0
```

KMP_AFFINITY="granularity=verbose,fine,proclist=[3,0,{1,2},{1,2}],explicit"

```
KMP_AFFINITY: pid 41464 tid 41464 thread 0 bound to OS proc set 3
KMP_AFFINITY: pid 41464 tid 41465 thread 1 bound to OS proc set 0
KMP_AFFINITY: pid 41464 tid 41466 thread 2 bound to OS proc set 1,2
KMP_AFFINITY: pid 41464 tid 41467 thread 3 bound to OS proc set 1,2
KMP_AFFINITY: pid 41464 tid 41468 thread 4 bound to OS proc set 3
KMP_AFFINITY: pid 41464 tid 41469 thread 5 bound to OS proc set 0
```

Low Level Affinity API

Instead of relying on the user to specify the OpenMP thread to OS proc binding by setting an environment variable before program execution starts (or by using the `kmp_settings` interface before the first parallel region is reached), each OpenMP thread can determine the desired set of OS procs on which it is to execute and bind to them with the `kmp_set_affinity` API call.

> **Caution**
> When you use this affinity interface you take complete control of the hardware resources on which your threads run. To do that sensibly you need to understand in detail how the logical CPUs, the enumeration of hardware threads controlled by the OS, map to the physical hardware of the specific machine on which you are running. That mapping can be, and likely is, different on different machines, so you risk binding machine-specific information into your code, which can result in explicitly forcing bad affinities when your code runs on a different machine. And if you are concerned with optimization at this level of detail, your code is probably valuable, and therefore will probably move to another machine.
>
> This interface may also allow you to ignore the resource limitations that were set by the program startup mechanism, such as Message Passing Interface (MPI), specifically to prevent multiple OpenMP processes on the same node from using the same hardware threads. Again, this can result in explicitly forcing affinities that cause bad performance, and the OpenMP runtime will neither prevent this from happening, nor warn you when it does. These are expert interfaces and you must use them with caution.
>
> It is recommended, therefore, to use the higher level affinity settings if you possibly can, because they are more portable and do not require this low level knowledge.

The C/C++ API interfaces follow, where the type name `kmp_affinity_mask_t` is defined in `omp.h`:

Syntax	Description
`int kmp_set_affinity (kmp_affinity_mask_t *mask)`	Sets the affinity mask for the current OpenMP thread to *`mask`, where *`mask` is a set of OS proc IDs that has been created using the API calls listed below, and the thread will only execute on OS procs in the set. Returns either a zero (0) upon success or a nonzero error code.
`int kmp_get_affinity (kmp_affinity_mask_t *mask)`	Retrieves the affinity mask for the current OpenMP thread, and stores it in *`mask`, which must have previously been initialized with a call to `kmp_create_affinity_mask()`. Returns either a zero (0) upon success or a nonzero error code.

Syntax	Description
`int kmp_get_affinity_max_proc (void)`	Returns the maximum OS proc ID that is on the machine, plus 1. All OS proc IDs are guaranteed to be between 0 (inclusive) and `kmp_get_affinity_max_proc()` (exclusive).
`void kmp_create_affinity_mask (kmp_affinity_mask_t *mask)`	Allocates a new OpenMP thread affinity mask, and initializes *`mask` to the empty set of OS procs. The implementation is free to use an object of `kmp_affinity_mask_t` either as the set itself, a pointer to the actual set, or an index into a table describing the set. Do not make any assumption as to what the actual representation is.
`void kmp_destroy_affinity_mask (kmp_affinity_mask_t *mask)`	Deallocates the OpenMP thread affinity mask. For each call to `kmp_create_affinity_mask()`, there should be a corresponding call to `kmp_destroy_affinity_mask()`.
`int kmp_set_affinity_mask_proc (int proc, kmp_affinity_mask_t *mask)`	Adds the OS proc ID proc to the set *`mask`, if it is not already. Returns either a zero (0) upon success or a nonzero error code.
`int kmp_unset_affinity_mask_proc (int proc, kmp_affinity_mask_t *mask)`	If the OS proc ID proc is in the set *`mask`, it removes it. Returns either a zero (0) upon success or a nonzero error code.
`int kmp_get_affinity_mask_proc (int proc, kmp_affinity_mask_t *mask)`	Returns 1 if the OS proc ID proc is in the set *`mask`; if not, it returns 0.

Once an OpenMP thread has set its own affinity mask via a successful call to `kmp_set_affinity()`, then that thread remains bound to the corresponding OS proc set until at least the end of the parallel region, unless reset via a subsequent call to `kmp_set_affinity()`.

Between parallel regions, the affinity mask (and the corresponding OpenMP thread to OS proc bindings) can be considered thread private data objects, and have the same persistence as described in the OpenMP Application Program Interface. For more information, see the OpenMP API specification (http://www.openmp.org), some relevant parts of which are provided below:

In order for the affinity mask and thread binding to persist between two consecutive active parallel regions, all three of the following conditions must hold:

- Neither parallel region is nested inside another explicit parallel region.
- The number of threads used to execute both parallel regions is the same.
- The value of the dyn-var internal control variable in the enclosing task region is false at entry to both parallel regions."

Therefore, by creating a parallel region at the start of the program whose sole purpose is to set the affinity mask for each thread, you can mimic the behavior of the `KMP_AFFINITY` environment variable with low-level affinity API calls, if program execution obeys the three aforementioned rules from the OpenMP specification.

The following example shows how these low-level interfaces can be used. This code binds the executing thread to the specified logical CPU:

Example

```
// Force the executing thread to execute on logical CPU i
// Returns 1 on success, 0 on failure.
int forceAffinity(int i)
{
kmp_affinity_mask_t mask;

kmp_create_affinity_mask(&mask);
kmp_set_affinity_mask_proc(i, &mask);

return (kmp_set_affinity(&mask) == 0);
}
```

This program fragment was written with knowledge about the mapping of the OS proc IDs to the physical processing elements of the target machine. On another machine, or on the same machine with a different OS installed, the program would still run, but the OpenMP thread to physical processing element bindings could differ and you might be explicitly force a bad distribution.

OpenMP* Memory Spaces and Allocators

For storage and retrieval variables, OpenMP* provides memory known as memory spaces. Different memory spaces have different traits. Depending on how a variable is to be used and accessed determines which memory space is appropriate for allocation of the variable.

Each memory space has a unique allocator that is used to allocate and deallocate memory in that space. The allocators allocate variables in contiguous space that does not overlap any other allocation in the memory space. Multiple memory spaces with different traits may map to a single memory resource.

The behavior of the allocator is affected by the allocator traits that you specify. The allocator traits, their possible values, and their default values are shown in the following table:

Allocator Trait	Values That Can Be Specified	Default Value
`access`	• `all` • `cgroup` • `pteam` • `thread`	All
`alignment`	A positive integer value that is a power of 2 specifying number of bytes	1 byte
`fallback`	• `abort_fb` • `allocator_fb` • `default_mem_fb` • `null_fb`	`default_mem_fb`
`fb_data`	An allocator handle	None
`partition`	• `blocked` • `environment` • `interleaved` • `nearest`	`environment`
`pinned`	• `true` • `false`	`false`

Allocator Trait	Values That Can Be Specified	Default Value
pool_size	a positive integer value	Implementation defined
sync_hint	• contended • uncontended • private • serialized	contended

The access trait specifies the accessibility of the allocated memory. The following are values you can specify for access:

- all

  This value indicates that the allocated memory must be accessible by all threads in the device where the memory allocation occurs.

  This is the default setting.
- cgroup

  This value indicates that the allocated memory must be accessible by all threads of the same contention group as the thread that requested the allocation. Accessing the allocated memory thread that is not part of the same contention group results in undefined behavior.
- pteam

  This value indicates that the allocated memory is accessible by all threads that bind to the same parallel region as the thread that requests the allocations. Access to the memory by a thread that does not bind to the same parallel region as the thread that allocated the memory results in undefined behavior.
- thread

  This value indicates that the memory allocated is accessible only by the thread that allocated it. Attempts to allocate the memory by another thread result in undefined behavior.

The alignment trait specifies how allocated variables will be aligned. Variables will be byte-aligned to at least the value specified for this trait. The default setting is 1 byte. Alignment can also be affected by directives and OpenMP runtime allocator routines that specify alignment requirements.

The fallback trait indicates how an allocator behaves if it is unable to satisfy an allocation request. The following are values you can specify for fallback:

- abort_fb

  This value indicates that the program terminates if the allocation request fails.
- allocator_fb

  If this value is specified and the allocation request fails, the allocation will be tried by the allocator specified by the fb_data trait.
- default_mem_fb

  This value indicates that a failed allocation request will be retried in the omp_default_mem_space memory space. All traits for the omp_default_mem_space allocator should be set to the default trait values, except the fallback trait should be set to null_fb. This is the default setting.
- null_fb

  This value indicates the allocator returns a zero value when an allocation request fails.

The fb_data trait lets you specify a fall back allocator to be used if the requested allocator fails to satisfy the allocation request. The fallback trait of the failing allocator must be set to allocator_fb in order for the allocator specified by the fb_data trait to be used.

The partition trait describes the partitioning of allocated memory over the storage resources represented by the memory space of the allocator. The following are values you can specify for partition:

- blocked

This value indicates the allocated memory is partitioned into blocks of memory of approximately equal size with one block per storage resource.

- `environment`

  This value indicates the allocated memory placement is determined by the runtime execution environment. This is the default setting.
- `interleaved`

  This value indicates the allocated memory is distributed in a round-robin fashion across the storage resources.
- `nearest`

  This value indicates that the allocated memory will be placed in the storage resource nearest to the thread that requested the allocation.

If the `pinned` trait has the value `true`, the allocator ensures each allocation made by the allocator will remain in the storage resource at the same location where it was allocated until it is deallocated. The default setting is `false`.

The value of `pool_size` is the total number of bytes of storage available to an allocator when there have been no allocations. The following affect `pool_size`:

- If the `access` trait has the value all, the value of `pool_size` is the limit for all allocations for all threads having access to the allocator.
- If the `access` trait of the allocator has the value `cgroup`, the value of `pool_size` is the limit for allocations made from the threads within the same contention group.
- For allocators with the `access` access trait value of `pteam`, the value of `pool_size` is the limit for allocations made within the same parallel team.
- If the `access` trait has the value `thread`, the value of `pool_size` is the limit for allocations made from each thread using the allocator.
- An allocation request for more space than the value of `pool_size` results in the allocator not fulfilling the allocation request.

The `sync_hint` trait describes the way that multiple threads can access an allocator. The following are values you can specify for `sync_hint`:

- `contended` or `uncontended`

  Value `contended` indicates that many threads are anticipated to make simultaneous allocation requests while the value `uncontended` indicates that few threads are anticipated to make simultaneous allocation. The default setting is `contended`.
- `private`

  This value indicates that all allocation requests will come from the same thread. Specifying `private` when this is not the case and two or more threads make allocation requests by the same allocator results in undefined behavior.
- `serialized`

  This value indicates that only one thread will request an allocation at a given time. The behavior is undefined if two threads request an allocation simultaneously by an allocator whose `sync_hint` value is serialized.

There are five predefined memory spaces in OpenMP:

- The system default memory is referred to as `omp_default_mem_space`.
- Large capacity memory is referred to as `omp_large_cap_mem_space`.
- High bandwidth memory is referred to as `omp_high_bw_mem_space`.
- Low latency memory is referred to as `omp_low_lat_mem_space`.
- Memory designed for optimal storage of constant values is referred to as `omp_const_mem_space`.

  It can be initialized with compile-time constant expressions or by using a firstprivate clause.

  Writing to variables in `omp_const_mem_space` results in undefined behavior.

The following table shows the predefined memory allocators, the memory space they are associated with, and the non-default memory trait values they possess.

Allocator Name	Associated Memory Space	Non-Default Trait Values
omp_default_mem_alloc	omp_default_mem_space	fallback=null_fb
omp_large_cap_mem_alloc	omp_large_cap_mem_space	none
omp_low_lat_mem_alloc	omp_low_lat_mem_space	none
omp_high_bw_mem_alloc	omp_high_bw_mem_space	none
omp_const_mem_alloc	omp_const_mem_space	none
omp_cgroup_mem_alloc	implementation/system defined	access=cgroup
omp_pteam_mem_alloc	implementation/system defined	access=pteam
omp_thread_mem_alloc	implementation/system defined	access=thread

OpenMP* Run-time Library Routines

OpenMP* Advanced Issues

This topic discusses how to use the OpenMP* library functions and environment variables and discusses some guidelines for enhancing performance with OpenMP.

OpenMP provides specific function calls, and environment variables. See the following topics to refresh your memory about the primary functions and environment variable used in this topic:

- OpenMP Run-time Library Routines
- OpenMP Environment Variables

To use the function calls, include the `omp.h` header file. This file is installed in the INCLUDE directory during the compiler installation and compile the application using the `/Qopenmp` (Windows*) or `-qopenmp` (Linux* and macOS) option.

The following example demonstrates how to use the OpenMP functions to print the alphabet and illustrates several important concepts:

1. When using functions instead of pragmas, your code must be rewritten; rewrites can mean extra debugging, testing, and maintenance efforts.
2. It becomes difficult to compile without OpenMP support.
3. It is very easy to introduce simple bugs, as in the loop (shown in example) that fails to print all the letters of the alphabet when the number of threads is not a multiple of 26.
4. You lose the ability to adjust loop scheduling without creating your own work-queue algorithm, which is a lot of extra effort. You are limited by your own scheduling, which is mostly likely static scheduling as shown in the example.

```
#include <stdio.h>
#include <omp.h>

int main(void) {
    int i;
    omp_set_num_threads(4);

    #pragma omp parallel private(i)
    {
        // OMP_NUM_THREADS is not a multiple of 26,
```

```
        // which can be considered a bug in this code.
        int LettersPerThread = 26 / omp_get_num_threads();
        int ThisThreadNum = omp_get_thread_num();
        int StartLetter = 'a'+ThisThreadNum*LettersPerThread;
        int EndLetter = 'a'+ThisThreadNum*LettersPerThread+LettersPerThread;

        for (i=StartLetter; i<EndLetter; i++) { printf("%c", i); }
    }
    printf("\n");
    return 0;
}
```

Debugging threaded applications is a complex process because debuggers change the run-time performance, which can mask race conditions. Even print statements can mask issues, because they use synchronization and operating system functions. OpenMP itself also adds some complications, because it introduces additional structure by distinguishing private variables and shared variables and inserts additional code. A debugger that supports OpenMP can help you to examine variables and step through threaded code. You can use Intel® Inspector to detect many hard-to-find threading errors analytically. Sometimes, a process of elimination can help identify problems without resorting to sophisticated debugging tools.

Remember that most mistakes are race conditions. Most race conditions are caused by shared variables that really should have been declared private. Start by looking at the variables inside the parallel regions and make sure that the variables are declared private when necessary. Next, check functions called within parallel constructs. By default, variables declared on the stack are private, but the C/C++ keyword `static` changes the variable to be placed on the global heap and therefore shared for OpenMP loops.

The `default(none)` clause can be used to help find those hard-to-spot variables. If you specify `default(none)`, then every variable must be declared with a data-sharing attribute clause. For example:

```
#pragma omp parallel for default(none) private(x,y) shared(a,b)
```

Another common mistake is using uninitialized variables. Remember that private variables do not have initial values upon entering a parallel construct. Use the `firstprivate` and `lastprivate` clauses to initialize them only when necessary, because doing so adds extra overhead.

If you still can't find the bug, then consider the possibility of reducing the scope. Try a binary-hunt. Force parallel sections to be serial again with `if(0)` on the parallel construct or commenting out the pragma altogether. Another method is to force large chunks of a parallel region to be critical sections. Pick a region of the code that you think contains the bug and place it within a critical section. Try to find the section of code that suddenly works when it is within a critical section and fails when it is not. Now look at the variables, and see if the bug is apparent. If that still doesn't work, try setting the entire program to run in serial by setting the compiler-specific environment variable `KMP_LIBRARY=serial`.

If the code is still not working, and you are not using any OpenMP API function calls, compile it without the `/Qopenmp` (Windows) or `-qopenmp` (Linux and macOS) option to make sure the serial version works. If you are using OpenMP API function calls, use the `/Qopenmp-stubs` (Windows) or `-qopenmp-stubs` (Linux and macOS) option.

Performance

OpenMP threaded application performance is largely dependent upon the following things:

- The underlying performance of the single-threaded code.
- CPU utilization, idle threads, and load balancing.
- The percentage of the application that is executed in parallel by multiple threads.
- The amount of synchronization and communication among the threads.
- The overhead needed to create, manage, destroy, and synchronize the threads, made worse by the number of single-to-parallel or parallel-to-single transitions called fork-join transitions.
- Performance limitations of shared resources such as memory, bus bandwidth, and CPU execution units.
- Memory conflicts caused by shared memory or falsely shared memory.

Performance always begins with a properly constructed parallel algorithm or application. For example, parallelizing a bubble-sort, even one written in hand-optimized assembly language, is not a good place to start. Keep scalability in mind; creating a program that runs well on two CPUs is not as efficient as creating one that runs well on *n* CPUs. With OpenMP, the number of threads is chosen by the compiler, so programs that work well regardless of the number of threads are highly desirable. Producer/consumer architectures are rarely efficient, because they are made specifically for two threads.

Once the algorithm is in place, make sure that the code runs efficiently on the targeted Intel® architecture; a single-threaded version can be a big help. Turn off the `/Qopenmp` (Windows) or `-qopenmp` (Linux and macOS) option to generate a single-threaded version, or build with the `/Qopenmp-stubs` (Windows) or `-qopenmp-stubs` (Linux and macOS) option, and run the single-threaded version through the usual set of optimizations.

Once you have gotten the single-threaded performance, it is time to generate the multi-threaded version and start doing some analysis.

Optimizations are really a combination of patience, experimentation, and practice. Make little test programs that mimic the way your application uses the computer resources to get a feel for what things are faster than others. Be sure to try the different scheduling clauses for the parallel sections of code. If the overhead of a parallel region is large compared to the compute time, you may want to use an `if` clause to execute the section serially.

OpenMP* Implementation-Defined Behaviors

This topic summarizes the behaviors that are described as implementation defined in the OpenMP* API specification.

NOTE
Internal Control Variables (ICVs) mentioned below are discussed in the OpenMP API specification.

Name	Description
`single` construct	The first thread that encounters the single construct executes the structured block.
`teams` construct	The number of teams that are created is equal to 1 if you don't specify the `num_teams` clause.
`dist_schedule` clause, `distribute` construct	If you don't specify the `dist_schedule` clause, then the schedule for the `distribute` construct is `static`.
`omp_set_num_threads` routine	If the argument is not a positive integer, then Intel's OpenMP implementation sets the value of the first element of the `nthreads-var` ICV of the current task to 1.
`omp_set_max_active_levels` routine	If the argument is a negative integer this call is ignored and the last valid setting is used.

Name	Description
`omp_get_max_active_levels` routine	When called from within any explicit parallel region the binding thread set, and binding region, if required, for the `omp_get_max_active_levels` region is the current task region.
`OMP_SCHEDULE` environment variable	If the value of the variable does not conform to the specified format then the value of the `run-sched-var` ICV is set to `static`.
`OMP_NUM_THREADS` environment variable	If any value of the list specified in the environment variable is negative then the whole list is ignored. If any value of the list is zero then this value is set to 1.
`OMP_PROC_BIND` environment variable	If the value is not `true`, `false`, or a comma separated list of `master` (deprecated), `primary`, `close`, or `spread`, then Intel's OpenMP implementation sets the value of `bind-var` ICV to false.
`OMP_DYNAMIC` environment variable	If the value is neither `true` nor `false`, then the implementation sets the value of `dyn-var` ICV to false.
`OMP_NESTED` environment variable	If the value is neither `true` nor `false`, then the implementation sets the value of `nest-var` ICV to false.
`OMP_STACKSIZE` environment variable	If the value does not conform to the specified format or the implementation cannot provide a stack of the specified size, then Intel's OpenMP implementation sets the value of `stacksize-var` ICV to the default size, which is specified as being from 1MB to 4MB depending on the architecture. On Linux* or macOS*, the implementation can set the value of `stacksize-var` ICV up to 256MB, respecting the operating system's stack size limit.
`OMP_MAX_ACTIVE_LEVELS` environment variable	If the value is a negative integer or is greater than the number of parallel levels an implementation can support, then Intel's OpenMP implementation sets the value of the `max-active-levels-var` ICV to 1.
`OMP_THREAD_LIMIT` environment variable	If the requested value is greater than the number of threads an implementation can support, or if the value is a negative integer, then Intel's OpenMP implementation sets the value of the `thread-limit-var` ICV to the maximum number of threads supported on a particular platform. If the requested value is zero then the implementation sets the value of the `thread-limit-var` ICV to 1.
Runtime library definitions	Intel's OpenMP implementation provides both the include file `omp.h` and `omp-tools.h` .

OpenMP* Examples

The following examples show how to use several OpenMP* features.

A Simple Difference Operator

This example shows a simple parallel loop where the amount of work in each iteration is different. Dynamic scheduling is used to improve load balancing.

The `for` pragma has a `nowait` clause because there is an implicit barrier at the end of the parallel region. Therefore it is not necessary to also have a barrier at the end of the `for` region.

```
void for1(float a[], float b[], int n) {
  int i, j;
  #pragma omp parallel shared(a,b,n) {
   #pragma omp for schedule(dynamic,1) private (i,j) nowait
    for (i = 1; i < n; i++)
       for (j = 0; j < i; j++)
         b[j + n*i] = (a[j + n*i] + a[j + n*(i-1)]) / 2.0;
  }
}
```

Two Difference Operators: for Loop Version

This example uses two parallel loops fused to reduce fork/join overhead. The first `for` pragma has a `nowait` clause because all the data used in the second loop is different than all the data used in the first loop.

```
void for2(float a[], float b[], float c[], float d[], int n, int m) {
  int i, j;
  #pragma omp parallel shared(a,b,c,d,n,m) private(i,j) {
    #pragma omp for schedule(dynamic,1) nowait
    for (i = 1; i < n; i++)
      for (j = 0; j < i; j++)
        b[j + n*i] = ( a[j + n*i] + a[j + n*(i-1)] )/2.0;
    #pragma omp for schedule(dynamic,1) nowait
    for (i = 1; i < m; i++)
      for (j = 0; j < i; j++)
        d[j + m*i] = ( c[j + m*i] + c[j + m*(i-1)] )/2.0;
  }
}
```

Two Difference Operators: sections Version

This example demonstrates the use of the `sections` pragma . The logic is identical to the preceding `for` pragma example, but uses a `sections` pragma instead of a `for` pragma . Here the speedup is limited to two because there are only two units of work whereas in the example above there are `(n-1) + (m-1)` units of work.

```
void sections1(float a[], float b[], float c[], float d[], int n, int m) {
  int i, j;
  #pragma omp parallel shared(a,b,c,d,n,m) private(i,j) {
    #pragma omp sections nowait {
      #pragma omp section
       for (i = 1; i < n; i++)
         for (j = 0; j < i; j++)
           b[j + n*i] = ( a[j + n*i] + a[j + n*(i-1)] )/2.0;
      #pragma omp section
       for (i = 1; i < m; i++)
```

```
        for (j = 0; j < i; j++)
          d[j + m*i] = ( c[j + m*i] + c[j + m*(i-1)] )/2.0;
    }
  }
}
```

Update a Shared Scalar

This example demonstrates how to use a `single` construct to update an element of the shared array `a`. The optional `nowait` clause after the first loop is omitted because it is necessary to wait at the end of the loop before proceeding into the `single` construct to avoid a race condition.

```
void sp_1a(float a[], float b[], int n) {
  int i;
  #pragma omp parallel shared(a,b,n) private(i) {
    #pragma omp for
      for (i = 0; i < n; i++)
        a[i] = 1.0 / a[i];
      #pragma omp single
        a[0] = MIN( a[0], 1.0 );
      #pragma omp for nowait
      for (i = 0; i < n; i++)
      b[i] = b[i] / a[i];
  }
}
```

Automatic Parallelization

The auto-parallelization feature of the Intel®C++ Compiler automatically translates serial portions of the input program into equivalent multithreaded code. Automatic parallelization determines the loops that are good worksharing candidates, performs the dataflow analysis to verify correct parallel execution, and partitions the data for threaded code generation as needed in programming with OpenMP* directives. The OpenMP* and auto-parallelization functionality provides the performance gains from shared memory on multiprocessor and dual core systems.

The auto-parallelizer analyzes the dataflow of the loops in the application source code and generates multithreaded code for those loops which can safely and efficiently be executed in parallel.

This behavior enables the potential exploitation of the parallel architecture found in symmetric multiprocessor (SMP) systems.

The guided auto-parallelization feature of the Intel®C++ Compiler helps you locate portions in your serial code that can be parallelized further. You can invoke guidance for parallelization, vectorization, or data transformation using specified compiler options of the `[Q]guide` series.

Automatic parallelization frees developers from having to:

- Find loops that are good worksharing candidates.
- Perform the dataflow analysis to verify correct parallel execution.
- Partition the data for threaded code generation as is needed in programming with OpenMP* directives.

Although OpenMP* directives enable serial applications to transform into parallel applications quickly, you must explicitly identify specific portions of your application code that contain parallelism and add the appropriate compiler directives. Auto-parallelization, which is triggered by the `[Q]parallel` option, automatically identifies those loop structures that contain parallelism. During compilation, the compiler automatically attempts to deconstruct the code sequences into separate threads for parallel processing. No other effort is needed.

NOTE In order to execute a program that uses auto-parallelization on Linux* or macOS systems, you must include the `-parallel` compiler option when you compile and link your program.

NOTE
Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

Serial code can be divided so that the code can execute concurrently on multiple threads. For example, consider the following serial code example.

Example 1: Original Serial Code

```
void ser(int *a, int *b, int *c) {
  for (int i=0; i<100; i++)
    a[i] = a[i] + b[i] * c[i];
}
```

The following example illustrates one method showing how the loop iteration space, shown in the previous example, might be divided to execute on two threads.

Example 2: Transformed Parallel Code

```
void par(int *a, int *b, int *c) {
  int i;
  // Thread 1
  for (i=0; i<50; i++)
    a[i] = a[i] + b[i] * c[i];
  // Thread 2
  for (i=50; i<100; i++)
    a[i] = a[i] + b[i] * c[i];
}
```

Auto-Vectorization and Parallelization

Auto-vectorization detects low-level operations in the program that can be done in parallel, and then converts the sequential program to process 2, 4, 8, or (up to) 16 elements in one operation, depending on the data type. In some cases, auto-parallelization and vectorization can be combined for better performance results.

The following example demonstrates how code can be designed to explicitly benefit from parallelization and vectorization. Assuming you compile the code shown below using the `[Q]parallel` option, the compiler will parallelize the outer loop and vectorize the innermost loop.

Example

```
#include <stdio.h>
#define ARR_SIZE 500 //Define array
int main() {
  int matrix[ARR_SIZE][ARR_SIZE];
  int arrA[ARR_SIZE]={10};
  int arrB[ARR_SIZE]={30};
  int i, j;
  for(i=0;i<ARR_SIZE;i++) {
```

Example

```
     for(j=0;j<ARR_SIZE;j++) { matrix[i][j] = arrB[i]*(arrA[i]%2+10); }
  } printf("%d\n",matrix[0][0]);
}
```

Compiling the example code with the correct options, the compiler should report results similar to the following:

```
vectorization.c(18) : (col. 6) remark: LOOP WAS VECTORIZED.
     vectorization.c(16) : (col. 3) remark: LOOP WAS AUTO-PARALLELIZED.
```

With the relatively small effort of adding OpenMP* directives to existing code you can transform a sequential program into a parallel program. The [Q]openmp option must be specifed to enable the OpenMP directives.

The following example demonstrates one method of using the OpenMP* pragmas within code.

Example

```
#include <stdio.h>
#define ARR_SIZE 100 //Define array
void foo(int ma[][ARR_SIZE], int mb[][ARR_SIZE], int *a, int *b, int *c);
int main() {
  int arr_a[ARR_SIZE];
  int arr_b[ARR_SIZE];
  int arr_c[ARR_SIZE];
  int i,j;
  int matrix_a[ARR_SIZE][ARR_SIZE];
  int matrix_b[ARR_SIZE][ARR_SIZE];
  #pragma omp parallel for
// Initialize the arrays and matrices.
  for(i=0;i<ARR_SIZE; i++) {
    arr_a[i]= i;
    arr_b[i]= i;
    arr_c[i]= ARR_SIZE-i;
    for(j=0; j<ARR_SIZE;j++) {
       matrix_a[i][j]= j;
       matrix_b[i][j]= i;
    }
  }
  foo(matrix_a, matrix_b, arr_a, arr_b, arr_c);
}
void foo(int ma[][ARR_SIZE], int mb[][ARR_SIZE], int *a, int *b, int *c)
{
  int i, num, arr_x[ARR_SIZE];
  #pragma omp parallel for private(num)
// Expresses the parallelism using the OpenMP pragma: parallel for.
// The pragma guides the compiler generating multithreaded code.
// Array arr_X, mb, b, and c are shared among threads based on OpenMP
// data sharing rules. Scalar num si specifed as private
// for each thread.
  for(i=0;i<ARR_SIZE;i++) {
     num = ma[b[i]][c[i]];
     arr_x[i]= mb[a[i]][num];
     printf("Values: %d\n", arr_x[i]); //prints values 0-ARR_SIZE-1
    }
}
```

NOTE
Options that use OpenMP are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

Using Parallelism Reports

To generate a parallelism report, use the `-opt-report-phase=`*par* (Linux* and macOS) or the `/Qopt-report-phase:`*par* option along with the `-opt-report=`*n* or `/Qopt-report:`*n* option. By default the auto-parallelism report generates a medium level of detail, where *n*`=2`. You can use `[Q]opt-report` option along with the `[Q]opt-report-phase` option if you want a greater or lesser level of detail. Specifying a value of '5' generates the maximum diagnostic details.

Run the report by entering commands similar to the following:

Operating System	Command
Linux*	`icpc -c -parallel -opt-report-phase=par -opt-report:5 sample.cpp`
macOS	`icl++ -c -parallel -opt-report-phase=par -opt-report:5 sample.cpp`
Windows*	`icl /c /Qparallel /Qopt-report-phase:par /Qopt-report:5 sample.cpp`

NOTE The `-c` (Linux* and macOS) or `/c` (Windows*) prevents linking and instructs the compiler to stop compilation after the object file is generated. The example is compiled without generating an executable.

The output, by default, produces a file with the same name as the object file, with `.optrpt` extension, and is written into the same directory as the object file. Using the above command-line entries, you will obtain an output file called `sample.optrpt`. Use the `[Q]opt-report-file` option to specify any other name for the output file that captures the report results. Use the arguments *stdout* or *stderr* to send the optimization report to stdout or stderr.

For example, assume you want a full diagnostic report on the following example code:

Example

```
void no_par(void) {
  int i;
  int a[1000];
  for (i=1; i<1000; i++) {
    a[i] = (i * 2) % i * 1 + sqrt(i);
    a[i] = a[i-1] + i;
  }
}
```

The following example output illustrates the diagnostic report generated by the compiler for the example code shown above. In most cases, the comment listed next to the line is self-explanatory.

Example Parallelism Report

```
procedure: no_par
sample.c(13):(3) remark #15048: DISTRIBUTED LOOP WAS AUTO-PARALLELIZED
sample.c(13):(3) remark #15050: loop was not parallelized: existence of parallel dependence
sample.c(19):(5) remark #15051: parallel dependence: proven FLOW dependence between a line 19,
and a line 19
```

For more information on options to generate reports see the Optimization Report Options topic.

Enabling Auto-parallelization

To enable the auto-parallelizer, use the `[Q]parallel` option. This option detects parallel loops capable of being executed safely in parallel, and automatically generates multi-threaded code for these loops.

> **NOTE** You may need to set the `KMP_STACKSIZE` environment variable to an appropriately large size to enable parallelization with this option.

> **NOTE**
> Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

An example of the command using auto-parallelization is as follows:

Commanding auto-parallelization in Linux*

```
icc -c -parallel prog.cpp
```

Commanding auto-parallelization in Windows*

```
icl /c /Qparallel prog.cpp
```

Commanding auto-parallelization in macOS
`icc -c -parallel prog.cpp`

Auto-parallelization uses two specific pragmas: `#pragma parallel` and `#pragma noparallel`.

The format of an auto-parallelization compiler pragma is below:

Syntax
`<prefix> <pragma>`

where `<prefix>` indicates `#pragma`, the `<prefix>` is followed by the pragma name, as in:

Syntax
`#pragma parallel`

The `#pragma parallel` pragma instructs the compiler to ignore dependencies that it assumes may exist and that would prevent correct parallelization in the immediately following loop. However, if dependencies are proven, they are not ignored. In addition, `parallel [always]` overrides the compiler heuristics that estimate the likelihood that parallelization of a loop increases performance. It allows a loop to be parallelized even if the compiler thinks parallelization may not improve performance. If the `ASSERT` keyword is added, as in `#pragma parallel [always [assert]]`, the compiler generates an error-level assertion message saying that the compiler analysis and cost model indicate that the loop cannot be parallelized.

The `#pragma noparallel` pragma disables auto-parallelization.

compiler option

Programming with Auto-parallelization

The auto-parallelization feature implements some concepts of OpenMP*, such as the worksharing construct (with the `PARALLEL for` directive). This section provides details on auto-parallelization.

Guidelines for Effective Auto-parallelization Usage

A loop can be parallelized if it meets the following criteria:

- The loop is countable at compile time: This means that an expression representing how many times the loop will execute (loop trip count) can be generated just before entering the loop.
- There are no `FLOW` (*READ* after *WRITE*), `OUTPUT` (*WRITE* after *WRITE*) or `ANTI` (*WRITE* after *READ*) loop-carried data dependencies. A loop-carried data dependency occurs when the same memory location is referenced in different iterations of the loop. At the compiler's discretion, a loop may be parallelized if any assumed inhibiting loop-carried dependencies can be resolved by run-time dependency testing.

The compiler may generate a run-time test for the profitability of executing in parallel for loop, with loop parameters that are not compile-time constants.

Coding Guidelines

Enhance the power and effectiveness of the auto-parallelizer by following these coding guidelines:

- Expose the trip count of loops whenever possible; use constants where the trip count is known and save loop parameters in local variables.
- Avoid placing structures inside loop bodies that the compiler may assume to carry dependent data, for example, procedure calls, ambiguous indirect references or global references.

Auto-parallelization Data Flow

For auto-parallelization processing, the compiler performs the following steps:

1. **Data flow analysis:** Computing the flow of data through the program.
2. **Loop classification:** Determining loop candidates for parallelization based on correctness and efficiency, as shown by Enabling Auto-parallelization.
3. **Dependency analysis:** Computing the dependency analysis for references in each loop nest.
4. **High-level parallelization:** Analyzing the dependency graph to determine loops that can execute in parallel, and computing run-time dependency.
5. **Data partitioning:** Examining data reference and partition based on the following types of access: *SHARED*, *PRIVATE*, and *FIRSTPRIVATE*.
6. **Multithreaded code generation:** Modifying loop parameters, generating entry/exit per threaded task, and generating calls to parallel run-time routines for thread creation and synchronization.

NOTE
Options that use OpenMP are available for both Intel® and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors than on non-Intel microprocessors includes: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, and thread affinity and binding.

Enabling Auto-parallelization

Enabling Further Loop Parallelization for Multicore Platforms

Parallelizing loops for multicore platforms is subject to certain conditions. Three requirements must be met for the compiler to parallelize a loop:

- The number of iterations must be known before entry into a loop to insure that the work can be divided in advance. A `do while` loop, for example, usually cannot be made parallel.
- There can be no jumps into or out of the loop.
- The loop iterations must be independent (no cross-iteration dependencies).

Correct results must not logically depend on the order in which the iterations are executed. There may be slight variations in the accumulated rounding error, for example, when the same quantities are added in a different order. In some cases, such as summing an array or other uses of temporary scalars, the compiler may be able to remove an apparent dependency by a simple transformation.

Potential aliasing of pointers or array references is another common impediment to safe parallelization. Two pointers are aliased if both point to the same memory location. The compiler may not be able to determine whether two pointers or array references point to the same memory location, for example, if they depend on function arguments, run-time data, or the results of complex calculations.

If the compiler cannot prove that pointers or array references are safe, it will not parallelize the loop, except in limited cases when it is deemed worthwhile to generate alternative code paths to test explicitly for aliasing at run-time.

An alternative way in C to assert that a pointer is not aliased is to use the `restrict` keyword in the pointer declaration, along with the `[Q]restrict` command-line option. The compiler will never parallelize a loop that it can prove to be unsafe.

If you know parallelizing a particular loop is safe and that potential aliases can be ignored, you can instruct the compiler to parallelize the loop using the `#pragma parallel` pragma.

Parallelizing Loops with Cross-iteration Dependencies

Before the compiler can auto-parallelize a loop, it must prove that the loop does not have potential cross-iteration dependencies that prevent parallelization. A cross-iteration dependency exists if a memory location is written to in an iteration of a loop and accessed (read from or written to) in another iteration of the loop. Cross-iteration dependencies often occur in loops that access overlapping array ranges, such as a loop that reads from `a(1:100)` and writes to `a(0:99)`.

Sometimes, even though a loop does not have cross-iteration dependencies, the compiler does not have enough information to prove it and does not parallelize the loop. In such cases, you can assist the compiler by providing additional information about the loop using the `#pragma parallel` pragma. Adding the `#pragma parallel` pragma before a `for` loop informs the compiler that the loop does not have cross-iteration dependencies. Auto-parallelization analysis ignores potential dependencies that it assumes could exist; however, the compiler still may not parallelize the loop if heuristics estimate parallelization is unlikely to increase performance of the loop.

The `#pragma parallel always` pragma has the same effect to ignore potential dependencies as the `#pragma parallel` pragma, but it also overrides the compiler heuristics that estimate the likelihood that parallelization of a loop would increase performance. It allows a loop to be parallelized even when the compiler estimates that parallelization might not improve performance.

The `#pragma noparallel` pragma prevents auto-parallelization of the immediately following `for` loop. Unlike `#pragma parallel`, which is a hint, the `noparallel` pragma is guaranteed to prevent parallelization of the following loop.

These pragmas take effect only if auto-parallelization is enabled by the option `[Q]parallel`.

Parallelizing Loops with Private Clauses

When you use the Guided Auto Parallelism feature, the compiler's auto-parallelizer gives you advice on where to alter your program to enhance parallelization. For instance, you may get advice to check if a condition (that the compiler could not prove) is true, and if true, to insert `#pragma parallel` in your source code so that the associated loop is parallelized when you recompile.

To specify that it is legal for each thread to create a new, private copy (not visible by other threads) of a variable, and replace the original variable in the loop with the new private variable, use the `#pragma parallel` pragma with the *private* clause. The *private* clause allows you to list scalar and array type variables and specify the number of array elements to privatize.

Use the *firstprivate* clause to specify private variables that need to be initialized with the original value before entering the parallel loop.

Use the *lastprivate* clause to specify those variables with a value you want to reuse after it exits a parallelized loop. When you use the *lastprivate* clause to handle a particular privatized variable, the value is copied to the original variable when it exits from the parallelized loop.

> **NOTE**
> Do not use the same variable in both *private* and *lastprivate* clauses for the same loop. You will get an error message.

Parallelizing Loops with External Function Calls

The compiler can only effectively analyze loops with a relatively simple structure. For example, the compiler cannot determine the thread safety of a loop containing external function calls because it does not know whether the function call might have side effects that introduce dependencies. You can invoke interprocedural optimization with the `[Q]ipo` option. Using this option gives the compiler the opportunity to analyze the called function for side effects.

Parallelizing Loops with OpenMP*

When the compiler is unable to automatically parallelize loops you know to be parallel, use OpenMP*. OpenMP* is the preferred solution because you understand the code better than the compiler and can express parallelism at a coarser granularity. Alternatively, automatic parallelization can be effective for nested loops, such as those in a matrix multiply. Moderately coarse-grained parallelism results from threading of the outer loop, allowing the inner loops to be optimized for fine-grained parallelism using vectorization or software pipelining.

Threshold Parameter to Parallelize Loops

If a loop can be parallelized, it does not necessarily mean that it should be parallelized. The compiler uses a threshold parameter to decide whether to parallelize a loop. The `[Q]par-threshold` compiler option adjusts this behavior. The threshold ranges from *0* to *100* , where *0* instructs the compiler to always parallelize a safe loop and *100* instructs the compiler to only parallelize those loops for which a performance gain is highly probable. Use the `[Q]par-report` option to determine which loops were parallelized. The compiler will also report which loops could not be parallelized and indicate probable reason(s) why. See OpenMP* and Parallel Processing Options for more information on the using these compiler options.

The following example illustrates using the options in combination.

Example code

```
void add (int k, float *a, float *b) {
  for (int i = 1; i < 10000; i++) {
   a[i] = a[i+k] + b[i];
  }
}
```

Entering a command-line compiler command similar to the following will result in the compiler issuing parallelization messages:

```
//Linux* and macOS
icpc -c -parallel -opt-report-phase=par -opt-report=3 add.cpp
```

The compiler might report results similar to those listed below:

Sample results

```
add.cpp
procedure:
add serial loop: line 2
anti data dependence assumed from line 2 to line 2, due to "a"
flow data dependence assumed from line 2 to line 2, due to "a"
flow data dependence assumed from line 2 to line 2, due to "a"
```

Because the compiler does not know the value of *k*, the compiler assumes the iterations depend on each other, for example if *k* equals -1, even if the actual case is otherwise. You can override the compiler by inserting the `#pragma parallel` pragma.

Example

```
void add(int k, float *a, float *b) {
  #pragma parallel
  for (int i = 0; i < 10000; i++) {
    a[i] = a[i+k] + b[i];
  }  }
```

Caution
Do not call this function with a value of *k* that is less than 10000; passing a value less than 10000 could lead to incorrect results.

Language Support for Auto-parallelization

This topic addresses specific C++ language features that better help to parallelize code.

Annotating Functions with Declarations

Annotating functions with the declaration:

```
//  (Windows* OS)
__declspec(concurrency_safe(cost(cycles) | profitable)) -OR-//  (Linux* OS)
__attribute__(concurrency_safe(cost(cycles) | profitable))
```

guides the compiler to parallelize more loops and straight-line code.

Using the `concurrency_safe` attribute indicates to the compiler that there are no unaffected side-effects and no illegal (or improperly synchronized) memory access interfences among multiple invocations of the annotated function or between an invocation of this annotated function and other statements in the program, if they are executed concurrently.

NOTE
For every function that is annotated with the `concurrency_safe` attribute, it is your responsibility to ensure that its side effects (if any) are acceptable (or expected), and the memory access interferences are properly synchronized.

The *cost* clause specifies the execution cycles of the annotated function for the compiler to perform parallelization profitability analysis while compiling its enclosing loops or blocks. The *profitable* clause indicates that the loops or blocks that contain calls to the annotated function are profitable to parallelize.

NOTE
The value of *cycles* is a 2-byte unsigned integer (unsigned short), its maximal value is 2^^{16-1}. If the cycle count is greater than 2^^{16-1}, the user should use *profitable* clause.

The following example illustrates the use of this declaration.

Example using __declspec(concurrency_safe(cost(cycles) | profitable))

```
#define N 10
#define M 40
#define NValue N

#if defined(COSTLOW)

// The function cost is ~5 cycles, the loop calling "foo" will not be parallellized
__declspec(concurrency_safe(cost(5)))
#elif defined(COSTHIGH)

// The function cost is ~100 cycles, so the loop calling "foo" will be paralleized
__declspec(concurrency_safe(cost(200)))
#elif defined(PROFITABLE)

// The function is profitable to be executed in parallel, so the loop calling "foo"
// should be paralleized.
__declspec(concurrency_safe(profitable))
#endif

__declspec(noinline)
int foo(float A[], float B[]) {
   for (int i = 0; i < N; i++) {
   B[i] = A[i];
   }
   return N;
}

int testp(float A[], float B[], float* In[], float* Out[]) {
   int i, j;
   for (i = 0; i < M; i++) {
     foo (A, B);
     for (j = 0; j < N; j++) {
       Out[i][j] = In[i][j] + (NValue*j);
     }
   }
   return N;
}

[C:/temp] icl -c -DCOSTLOW -Qparallel -Qpar-report2 -Qansi-alias v.cpp
C:\temp\v.cpp(28): (col. 3) remark: loop was not parallelized: insufficient computational work.

[C:/temp] icl -c -DCOSTHIGH -Qparallel -Qpar-report -Qansi-alias v.cpp
C:\temp\v.cpp(28): (col. 3) remark: LOOP WAS AUTO-PARALLELIZED.

[C:/temp] icl -c -DPROFITABLE -Qparallel -Qpar-report -Qansi-alias v.cpp
C:\temp\v.cpp(28): (col. 3) remark: LOOP WAS AUTO-PARALLELIZED.
```

Vectorization

Vectorization is the process of converting an algorithm from a scalar implementation, which does an operation one pair of operands at a time, to a vector process where a single instruction can refer to a vector (a series of adjacent values).

Automatic Vectorization

The automatic vectorizer (also called the auto-vectorizer) is a component of the compiler that automatically uses SIMD instructions in the Intel® Streaming SIMD Extensions (Intel® SSE, Intel® SSE2, Intel® SSE3 and Intel® SSE4), Supplemental Streaming SIMD Extensions (SSSE3) instruction sets, Intel® Advanced Vector Extensions (Intel® AVX, Intel® AVX2) instruction sets, and Intel® Advanced Vector Extensions 512 (Intel® AVX-512) instruction set. The vectorizer detects operations in the program that can be done in parallel and converts the sequential operations to parallel; for example, the vectorizer converts the sequential SIMD instruction that processes up to 16 elements into a parallel operation, depending on the data type.

Automatic vectorization occurs when the compiler generates packed SIMD instructions to unroll a loop. Because the packed instructions operate on more than one data element at a time, the loop executes more efficiently. This process is referred to as auto-vectorization only to emphasize that the compiler identifies and optimizes suitable loops on its own, without external input. However, it is useful to note that in some cases, certain keywords or directives may be applied in the code for auto-vectorization to occur.

The compiler supports a variety of auto-vectorizing hints that can help the compiler to generate effective vector instructions. Automatic vectorization is supported on IA-32 (for C++ only) and Intel® 64 architectures. Intel® Advisor, a separate tool included in the Intel® oneAPI Base Toolkit, provides a Vectorization Advisor feature that can analyze the compiler's optimization reports and make recommendations for enhancing vectorization.

> **NOTE**
> This option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

Vectorization Programming Guidelines

The goal of including the vectorizer component in the Intel® C++ Compiler Classic is to exploit single-instruction multiple data (SIMD) processing automatically. Users can help by supplying the compiler with additional information; for example, by using auto-vectorizer hints or pragmas.

> **NOTE**
> This option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

Guidelines to Vectorize Innermost Loops

Follow these guidelines to vectorize innermost loops bodies.

Use:

- Straight-line code (a single basic block).

- Vector data only (arrays and invariant expressions on the right hand side of assignments). Array references can appear on the left hand side of assignments.
- Only assignment statements.

Avoid:

- Function calls (other than math library calls).
- Non-vectorizable operations (either because the loop cannot be vectorized, or because an operation is emulated through a number of instructions).
- Mixing vectorizable types in the same loop (leads to lower resource utilization).
- Data-dependent loop exit conditions (leads to loss of vectorization).

To make your code vectorizable, you need to edit your loops. You should only make changes that enable vectorization, and avoid these common changes:

- Loop unrolling, which the compiler performs automatically.
- Decomposing one loop with several statements in the body into several single-statement loops.

Restrictions

There are a number of restrictions that you should consider. Vectorization depends on two major factors: hardware and style of source code.

Factor	Description
Hardware	The compiler is limited by restrictions imposed by the underlying hardware. Intel® Streaming SIMD Extensions (Intel® SSE) has vector memory operations that are limited to stride-1 accesses with a preference to 16-byte-aligned memory references. This means that if the compiler abstractly recognizes a loop as vectorizable, it still might not vectorize it for a distinct target architecture.
Style of source code	The style in which you write source code can inhibit vectorization. For example, a common problem with global pointers is that they often prevent the compiler from being able to prove that two memory references refer to distinct locations. Consequently, this prevents certain reordering transformations.

Many stylistic issues that prevent automatic vectorization by compilers are found in loop structures. The ambiguity arises from the complexity of the keywords, operators, data references, pointer arithmetic, and memory operations within the loop bodies.

By understanding these limitations and by knowing how to interpret diagnostic messages, you can modify your program to overcome the known limitations and enable effective vectorization.

Guidelines for Writing Vectorizable Code

Follow these guidelines to write vectorizable code:

- Use simple `for` loops. Avoid complex loop termination conditions – the upper iteration limit must be invariant within the loop. For the innermost loop in a nest of loops, you could set the upper limit iteration to be a function of the outer loop indices.
- Write straight-line code. Avoid branches such as `switch`, `goto`, or `return` statements; most function calls; or `if` constructs that cannot be treated as masked assignments.
- Avoid dependencies between loop iterations or at the least, avoid read-after-write dependencies.
- Try to use array notations instead of the use of pointers. C programs in particular impose very few restrictions on the use of pointers; aliased pointers may lead to unexpected dependencies. Without help, the compiler often cannot tell whether it is safe to vectorize code containing pointers.
- Wherever possible, use the loop index directly in array subscripts instead of incrementing a separate counter for use as an array address.
- Access memory efficiently:

  - Favor inner loops with unit stride.
  - Minimize indirect addressing.
  - Align your data to 16-byte boundaries (for Intel® SSE instructions).
- Choose a suitable data layout with care. Most multimedia extension instruction sets are rather sensitive to alignment. The data movement instructions of Intel® SSE, for example, operate much more efficiently on data that is aligned at a 16-byte boundary in memory. Therefore, the success of a vectorizing compiler also depends on its ability to select an appropriate data layout which, in combination with code restructuring (like loop peeling), results in aligned memory accesses throughout the program.
- Use aligned data structures: Data structure alignment is the adjustment of any data object in relation with other objects.

  You can use the declaration `__declspec(align)`.

  > **Caution** Use this hint with care. Incorrect usage of aligned data movements result in an exception when using Intel® SSE.

- Use structure of arrays (SoA) instead of array of structures (AoS): An array is the most common type of data structure that contains a contiguous collection of data items that can be accessed by an ordinal index. You can organize this data as an array of structures (AoS) or as a structure of arrays (SoA). While AoS organization is excellent for encapsulation, it can be a hindrance for use of vector processing. To make vectorization of the resulting code more effective, you can also select appropriate data structures.

Dynamic Alignment Optimizations

Dynamic alignment optimizations can improve the performance of vectorized code, especially for long trip count loops. Disabling such optimizations can decrease performance, but it may improve bitwise reproducibility of results, factoring out data location from possible sources of discrepancy.

To enable or disable dynamic data alignment optimizations, specify the option `Qopt-dynamic-align[-]` (Windows) or `[no-]qopt-dynamic-align[-]` (Linux).

Use Aligned Data Structures

Data structure alignment is the adjustment of any data object with relation to other objects. The Intel® C++ Compiler Classic may align individual variables to start at certain addresses to speed up memory access. Misaligned memory accesses can incur large performance losses on certain target processors that do not support them in hardware.

Alignment is a property of a memory address, expressed as the numeric address modulo of powers of two. In addition to its address, a single datum also has a size. A datum is called 'naturally aligned' if its address is aligned to its size, otherwise it is called 'misaligned'. For example, an 8-byte floating-point datum is naturally aligned if the address used to identify it is aligned to eight (8).

A data structure is a way of storing data in a computer so that it can be used efficiently. Often, a carefully chosen data structure allows a more efficient algorithm to be used. A well-designed data structure allows a variety of critical operations to be performed, using as little resources (execution time and memory space) as possible.

```
struct MyData{
   short   Data1;
   short   Data2;
   short   Data3;
};
```

In the example data structure above, if the type `short` is stored in two bytes of memory then each member of the data structure is aligned to a boundary of two bytes. `Data1` would be at offset `0`, `Data2` at offset `2` and `Data3` at offset `4`. The size of this structure is six bytes. The type of each member of the structure usually has a required alignment, meaning that it is aligned on a pre-determined boundary, unless you request otherwise. In cases where the compiler has taken sub-optimal alignment decisions, you can use the declaration `declspec(align(base,offset))`, where `0 <= offset < base` and `base` is a power of two, to allocate a data structure at offset from a certain base.

Consider as an example, that most of the execution time of an application is spent in a loop of the following form:

```
double a[N], b[N];
  ...
for (i = 0; i < N; i++){ a[i+1] = b[i] * 3; }
```

If the first element of both arrays is aligned at a 16-byte boundary, then either an unaligned load of elements from `b` or an unaligned store of elements into `a` must be used after vectorization.

In this instance, peeling off an iteration does not help but you can enforce the alignment shown below. This alignment results in two aligned access patterns after vectorization (assuming an 8-byte size for doubles):

```
__declspec(align(16, 8))  double a[N];
__declspec(align(16, 0))  double b[N];
/* or simply "align(16)"  */
```

If pointer variables are used, the compiler is usually not able to determine the alignment of access patterns at compile time. Consider the following simple `fill()` function:

```
void fill(char *x) {
  int i;
  for (i = 0; i < 1024; i++){ x[i] = 1; }
}
```

Without more information, the compiler cannot make any assumption on the alignment of the memory region accessed by the above loop. At this point, the compiler may decide to vectorize this loop using unaligned data movement instructions or, generate the runtime alignment optimization shown here:

```
peel = x & 0x0f;
if (peel != 0) {
  peel = 16 - peel;
  /* runtime peeling loop */
  for (i = 0; i < peel; i++) { x[i] = 1; }
}

/* aligned access */
for (i = peel; i < 1024; i++) { x[i] = 1; }
```

Runtime optimization provides a generally effective way to obtain aligned access patterns at the expense of a slight increase in code size and testing. If incoming access patterns are aligned at a 16-byte boundary, you can avoid this overhead with the hint `__assume_aligned(x, 16);` in the function to convey this information to the compiler.

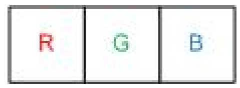
For example, suppose you can introduce an optimization in the case where a block of memory with address `n2` is aligned on a 16-byte boundary. You could use `_assume(n2%16==0)`.

Caution Incorrect use of aligned data movements result in an exception for Intel® SSE.

Use Structure of Arrays Versus Array of Structures

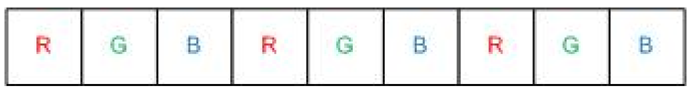
The most common and well-known data structure is the array that contains a contiguous collection of data items, which can be accessed by an ordinal index. This data can be organized as an array of structures (AoS) or as a structure of arrays (SoA). While AoS organization works excellently for encapsulation, for vector processing it works poorly.

You can select appropriate data structures to make vectorization of the resulting code more effective. To illustrate this point, compare the traditional array of structures (AoS) arrangement for storing the `r`, `g`, `b` components of a set of three-dimensional points with the alternative structure of arrays (SoA) arrangement for storing this set.



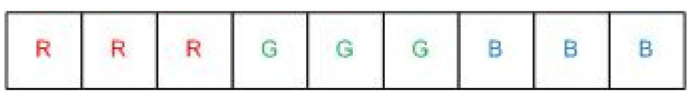
For example, a point structure with data in an AoS arrangement:

```
struct Point{
   float r;
   float g;
   float b;
}
```



For example, a points structure with data in a SoA arrangement:

```
struct Points{
   float* x;
   float* y;
   float* z;
}
```



With the AoS arrangement, a loop that visits all components of an RGB point before moving to the next point exhibits a good locality of reference. This is because all elements in the fetched cache lines are used. The disadvantage of the AoS arrangement is that each individual memory reference in such a loop exhibits a non-unit stride, which, in general, adversely affects vector performance. Furthermore, a loop that visits only one component of all points exhibits less satisfactory locality of reference because many of the elements in the fetched cache lines remain unused.

With the SoA arrangement, the unit-stride memory references are more amenable to effective vectorization and still exhibit good locality of reference within each of the three data streams. Consequently, an application that uses the SoA arrangement may outperform an application based on the AoS arrangement when compiled with a vectorizing compiler. This performance difference may not be obviously apparent during the early implementation phase.

Before you start vectorization, try out some simple rules:

- Make your data structures vector-friendly.
- Make sure that inner loop indices correspond to the outermost (last) array index in your data (row-major order).
- Use structure of arrays over array of structures.

For instance when dealing with three-dimensional coordinates, use three separate arrays for each component (SoA), instead of using one array of three-component structures (AoS). To avoid dependencies between loops that will eventually prevent vectorization, use three separate arrays for each component (SoA), instead of one array of three-component structures (AoS). When you use the AoS arrangement, each iteration produces one result by computing XYZ, but it can at best use only 75% of the SSE unit because the fourth component is not used. Sometimes, the compiler may use only one component (25%). When you use the SoA arrangement, each iteration produces four results by computing XXXX, YYYY and ZZZZ, using 100% of the SSE unit. A drawback for the SoA arrangement is that your code will likely be three times as long.

If your original data layout is in AoS format, you may want to consider a conversion to SoA before the critical loop:

- Use the smallest data types that give the needed precision to maximize potential SIMD width. (If only 16-bits are needed, using a `short` rather than an `int` can make the difference between 8-way or four-way SIMD parallelism.)
- Avoid mixing data types to minimize type conversions.
- Avoid operations not supported in SIMD hardware.
- Use all the instruction sets available for your processor. Use the appropriate command line option for your processor type, or select the appropriate IDE option (Windows only):
  - **Project** > **Properties** > **C/C++** > **Code Generation** > **Intel Processor-Specific Optimization**, if your application runs only on Intel® processors.
  - **Project** > **Properties** > **C/C++** > **Code Generation** > **Enable Enhanced Instruction Set**, if your application runs on compatible, non-Intel processors.
- Vectorizing compilers usually have some built-in efficiency heuristics to decide whether vectorization is likely to improve performance. The Intel® C++ Compiler Classic disables vectorization of loops with many unaligned or non-unit stride data access patterns. If experimentation reveals that vectorization improves performance, you can override this behavior using the `#pragma vector always` hint before the loop. The compiler vectorizes any loop regardless of the outcome of the efficiency analysis (provided that vectorization is safe).

compiler option

Use Automatic Vectorization

Automatic vectorization is supported on IA-32and Intel® 64 architectures. The information below will guide you in setting up the auto-vectorizer.

Vectorization Speedup

Where does the vectorization speedup come from? Consider the following sample code, where `a`, `b`, and `c` are integer arrays:

```
for (i=0;i<=MAX;i++)
   c[i]=a[i]+b[i];
```

If vectorization is not enabled, and you compile using the `O1`, `-no-vec-` (Linux), or `/Qvec-` (Windows) option, the compiler processes the code with unused space in the SIMD registers, even though each register can hold three additional integers. If vectorization is enabled (compiled using `O2` or higher options), the compiler may use the additional registers to perform four additions in a single instruction. The compiler looks for vectorization opportunities whenever you compile at default optimization (`O2`) or higher.

NOTE
This option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

Tip
This tip is only for the Intel®C++ (icc) Classic Compiler. To allow comparisons between vectorized and non-vectorized code, disable vectorization using the `-no-vec` (Linux or macOS) or `/Qvec-` (Windows) option; enable vectorization using the `O2` option.

To learn if a loop was vectorized or not, enable generation of the optimization report using the options `qopt-report=1 qopt-report-phase=vec` (Linux and macOS) or `Qopt-report:1 Qopt-report-phase:vec` (Windows) options. These options generate a separate report in an `*.optrpt` file that includes optimization messages. In Microsoft Visual Studio, the program source is annotated with the report's messages, or you can read the resulting `.optrpt` file using a text editor. A message appears for every loop that is vectorized, for example:

```
icl /Qopt-report:1 /Qopt-report-phase:vec  Multiply.c
Multiply.c(92): (col. 5) remark: LOOP WAS VECTORIZED.
```

The source line number (92 in the above example) refers to either the beginning or the end of the loop.

To get details about the type of loop transformations and optimizations that took place, use the `[Q]opt-report-phase` option by itself or along with the `[Q]opt-report` option.

To get information on if the loop was vectorized using the Microsoft Visual Studio IDE, select **Project** > **Properties** > **C/C++** > **Diagnostics** > **Optimization Diagnostic Level** as **Level 1 (/Qopt-report:1)** and **Optimization Diagnostic Phase** as **Loop Nest Optimization (/Qopt-report-phase:loop)**. To get a diagnostic message for every loop that was not vectorized, with a brief explanation of why the loop was not vectorized, select `/Qopt-report-phase:vec`.

Linux

To evaluate performance enhancement, run `vec_samples`:

1. Source an environment script such as `compilervars.sh` or the `compilervars.csh` in the `<installdir>/bin` directory and use the attribute appropriate for the architecture.
2. Navigate to the `<install-dir>\Samples\<locale>\C++\` directory. This application multiplies a vector by a matrix using the following loop:

```
for (j = 0;j < size2; j++) { b[i] += a[i][j] * x[j]; }
```

3. Build and run the application, first without enabling auto-vectorization. The default `O2` optimization enables vectorization, so you need to disable it with a separate option.

```
icc -O2 -no-vec  Multiply.c -o NoVectMult
./NoVectMult
```

4. Build and run the application, this time with auto-vectorization.

```
icx -O2 -qopt-report=3 -vec Multiply.c -o VectMult
./VectMult
```

Windows

To evaluate performance enhancement, run `vec_samples`:

1. Under the **Start** menu item for your product, select an icon under **Compiler and Performance Libraries** > **Command Prompt with Intel Compiler** for Classic Compilers or

2. Navigate to the `<install-dir>\Samples\<locale>\C++\`directory. On Windows, unzip the sample project `vec_samples.zip` to a writable directory. This small application multiplies a vector by a matrix using the following loop:

```
for (j = 0;j < size2; j++) { b[i] += a[i][j] * x[j]; }
```

3. Build and run the application, first without enabling auto-vectorization. The default `O2` optimization enables vectorization, so you need to disable it with a separate option.

```
icl /O2 /Qvec- Multiply.c /FeNoVectMult
NoVectMult
```

4. Build and run the application, this time with auto-vectorization.

```
icl /O2 /Qopt-report:3 /Qvec Multiply.c /FeVectMult
VectMult
```

When you compare the timing of the two runs, you may see that the vectorized version runs faster. The time for the non-vectorized version is only slightly faster than would be obtained by compiling with the `O1` option.

Obstacles to Vectorization

The following issues do not always prevent vectorization, but frequently cause the compiler to decide that vectorization would not be worthwhile.

- **Non-contiguous memory access:** Four consecutive integers or floating-point values, or two consecutive doubles, may be loaded directly from memory in a single SSE instruction. But if the four integers are not adjacent, they must be loaded separately using multiple instructions, which is considerably less efficient. The most common examples of non-contiguous memory access are loops with non-unit stride or with indirect addressing, shown in the examples below. The compiler rarely vectorizes these loops, unless the amount of computational work is larger compared to the overhead from non-contiguous memory access.

```
// arrays accessed with stride 2
for (int i=0; i<SIZE; i+=2)  b[i] += a[i] * x[i];

// inner loop accesses a with stride SIZE
for (int j=0; j<SIZE; j++)  {
  for (int i=0; i<SIZE; I++)   b[i] += a[i][j] * x[j];
}

// indirect addressing of x using index array
  for (int i=0; i<SIZE; i+=2)  b[i] += a[i] * x[index[i]];
```

  The typical message from the vectorization report is: `vectorization possible but seems inefficient`, although indirect addressing may also result in the following report: `existence of vector dependence`.
- **Data dependencies:** Vectorization entails changes in the order of operations within a loop, since each SIMD instruction operates on several data elements at once. Vectorization is only possible if this change of order does not change the results of the calculation.
  - The simplest case is when data elements that are written (stored to) do not appear in any other iteration of the individual loop. In this case, all the iterations of the original loop are independent of each other, and can be executed in any order, without changing the result. The loop may be safely executed using any parallel method, including vectorization.
  - When a variable is written in one iteration and read in a subsequent iteration, there is a read-after-write dependency, also known as a flow dependency, for example:

```
A[0]=0;
for (j=1; j<MAX; j++)  A[j]=A[j-1]+1;
          // this is equivalent to:
   A[1]=A[0]+1;
```

```
   A[2]=A[1]+1;
   A[3]=A[2]+1;
   A[4]=A[3]+1;
```

The value of `j` is propagated to all `A[j]`. This cannot safely be vectorized: if the first two iterations are executed simultaneously by a SIMD instruction, the value of `A[1]` is used by the second iteration before it has been calculated by the first iteration.

- When a variable is read in one iteration and written in a subsequent iteration, this is a write-after-read dependency, also known as an anti-dependency, for example:

```
for (j=1; j<MAX; j++)  A[j-1]=A[j]+1;
          // this is equivalent to:
   A[0]=A[1]+1;
   A[1]=A[2]+1;
   A[2]=A[3]+1;
   A[3]=A[4]+1;
```

This write-after-read dependency is not safe for general parallel execution, since the iteration with the write may execute before the iteration with the read. No iteration with a higher value of `j` can complete before an iteration with a lower value of `j`, and so vectorization is safe (it gives the same result as non-vectorized code).

The following example may not be safe, since vectorization might cause some elements of `A` to be overwritten by the first SIMD instruction before being used for the second SIMD instruction.

```
for (j=1; j<MAX; j++)  {
  A[j-1]=A[j]+1;
}

   // this is equivalent to:
   A[0]=A[1]+1;
   A[1]=A[2]+1;
   A[2]=A[3]+1;
   A[3]=A[4]+1;
```

- Read-after-read situations are not really dependencies, and do not prevent vectorization or parallel execution. If a variable is unwritten, it does not matter how often it is read.
- Write-after-write, or output dependencies, where the same variable is written to in more than one iteration, are generally unsafe for parallel execution, including vectorization.
- One important exception that contains all of the above types of dependency is:

```
sum=0;
for (j=1; j<MAX; j++)  sum = sum + A[j]*B[j]
```

Although `sum` is both read and written in every iteration, the compiler recognizes such reduction idioms, and is able to vectorize them safely. The loop in the first example was another example of a reduction, with a loop-invariant array element in place of a scalar.

These types of dependencies between loop iterations are sometimes known as loop-carried dependencies.

The above examples are of proven dependencies. The compiler cannot safely vectorize a loop if there is even a potential dependency. For example:

```
for (i = 0; i < size; i++) { c[i] = a[i] * b[i]; }
```

In the above example, the compiler needs to determine whether, for some iteration `i`, `c[i]` might refer to the same memory location as `a[i]` or `b[i]` for a different iteration. Such memory locations are sometimes said to be aliased. For example, if `a[i]` pointed to the same memory location as `c[i-1]`, there would be a read-after-write dependency. If the compiler cannot exclude this possibility, it will not vectorize the loop unless you provide the compiler with hints.

Help the Compiler Vectorize

Sometimes the compiler has insufficient information to decide to vectorize a loop. There are several ways to provide additional information to the compiler:

- **Pragmas:**
  - `#pragma ivdep`: may be used to tell the compiler that it may safely ignore any potential data dependencies. (The compiler will not ignore proven dependencies). Use of this pragma when there are dependencies may lead to incorrect results.

    There are cases where the compiler cannot tell by a static dependency analysis that it is safe to vectorize. Consider the following loop:

```
void copy(char *cp_a, char *cp_b, int n) {
  for (int i = 0; i < n; i++) { cp_a[i] = cp_b[i]; }
}
```

Without more information, a vectorizing compiler must conservatively assume that the memory regions accessed by the pointer variables `cp_a` and `cp_b` may (partially) overlap, which can cause potential data dependencies that prohibit straightforward conversion of this loop into SIMD instructions. At this point, the compiler may decide to keep the loop serial or generate a runtime test for overlap, where the loop in the true-branch can be converted into SIMD instructions:

```
if (cp_a + n < cp_b || cp_b + n < cp_a)
          /* vector loop */
  for (int i = 0; i < n; i++) cp_a[i] = cp_b [I];
  else
          /* serial loop */
  for (int i = 0; i < n; i++) cp_a[i] = cp_b[i];
```

Runtime data-dependency testing provides a way to exploit implicit parallelism in C or C++ code at the expense of a slight increase in code size and testing overhead. If the function copy is only used in specific ways, you can help the compiler:

- If the function is mainly used for small values of `n` or for overlapping memory regions, you can prevent vectorization and the corresponding runtime overhead by inserting a `#pragma novector` hint before the loop.
- Conversely, if the loop is guaranteed to operate on non-overlapping memory regions, you can provide this information to the compiler by means of a `#pragma ivdep` hint before the loop. This tells the compiler that conservatively assumed data dependencies that prevent vectorization can be ignored and results in vectorization of the loop without runtime data-dependency testing.

```
#pragma ivdep
void copy(char *cp_a, char *cp_b, int n) {
  for (int i = 0; i < n; i++) { cp_a[i] = cp_b[i]; }
}
```

NOTE You can also use the `restrict` keyword.

- `#pragma loop count (n)`: gives the typical trip count of the loop. This helps the compiler decide if vectorization is worthwhile, or if it should generate alternative code paths for the loop.
- `#pragma vector always`: asks the compiler to vectorize the loop.
- `#pragma vector align`: asserts that data within the following loop is aligned (to a 16-byte boundary, for Intel® SSE instruction sets).
- `#pragma novector`: asks the compiler not to vectorize a particular loop.
- `#pragma vector nontemporal`: gives a hint to the compiler that data will not be reused, and to use streaming stores that bypass cache.

- **Keywords:** The `restrict` keyword is used to assert that the memory referenced by a pointer is not aliased. The keyword requires the use of the `[Q]restrict` or `[Q]std=c99` compiler option. The example under `#pragma ivdep` above can also be handled using the `restrict` keyword.

  You may use the `restrict` keyword in the declarations of `cp_a` and `cp_b`, as shown below, to inform the compiler that each pointer variable provides exclusive access to a certain memory region. The `restrict` qualifier in the argument list lets the compiler know that there are no other aliases to the memory where the pointers point. The pointer where it is used provides the only means of accessing the memory in the scope where the pointers live. Even if the code gets vectorized without the `restrict` keyword, the compiler checks for aliasing at runtime, if the `restrict` keyword was used. You may have to use an extra compiler option, such as `[Q]restrict` option for the Intel® C++ Classic Compiler.

```
void copy(char * __restrict cp_a, char * __restrict cp_b, int n) {
  for (int i = 0; i < n; i++) cp_a[i] = cp_b[i];
}
```

  This method is best used when the exclusive access property holds for the pointer variables in your code with many loops, because it avoids annotating each of the vectorizable loops individually. Both the loop-specific `#pragma ivdep` hint, and the pointer variable-specific `restrict` hint must be used with care because incorrect usage may change the semantics intended in the original program.

  Another example is the following loop that may also not get vectorized because of a potential aliasing problem between pointers `a`, `b`, and `c`:

```
void add(float *a, float *b, float *c) {
  for (int i=0; i<SIZE; i++) { c[i] += a[i] + b[i]; }
}
```

  If the `restrict` keyword is added to the parameters, the compiler assumes that you will not access the memory in question with any other pointer and vectorize the code properly:

```
// let the compiler know, the pointers are safe with restrict
void add(float * __restrict a, float * __restrict b, float * __restrict c) {
  for (int i=0; i<SIZE; i++) { c[i] += a[i] + b[i]; }
}
```

  The down-side of using `restrict` is that not all compilers support this keyword, so your source code may lose portability. If you care about source code portability you may want to consider using the `[Q]ansi-alias` compiler option instead. Compiler options work globally, so you must make sure they do not cause harm to other code fragments.
- **Options/switches:** You can use options to enable different levels of optimizations to achieve automatic vectorization:
  - **Interprocedural optimization (IPO):** Enable IPO using the `[Q]ip` option within a single source file, or using `[Q]ipo` option across source files. You provide the compiler with additional information (trip counts, alignment, or data dependencies) about a loop. Enabling IPO may also allow inlining of function calls.
  - **Disambiguation of pointers and arrays:** Use the options `-fno-alias` (Linux or macOS) or `/Oa` (Windows) to assert there is no aliasing of memory references, that is, the same memory location is not accessed via different arrays or pointers. Other options make more limited assertions, for example, `-fargument-noalias` (Linux or macOS) or `/Qalias-args-` (Windows) asserts that function arguments cannot alias each other (they cannot overlap).

    The `/Qansi-alias` (`-fargument-alias`) options allow the compiler to assume strict adherence to the aliasing rules in the ISO C standard. Use these options responsibly; if you use these options when memory is aliased it may lead to incorrect results.

NOTE When you specify the `[Q]ansi-alias` option, the ansi-alias checker is enabled by default. To disable the ansi-alias checker, you must specify `-no-ansi-alias-check` (Linux and macOS) or `/Qansi-alias-check` (Windows).

Use the `[Q]ansi-alias-check` option to enable the ansi-alias checker. The ansi-alias checker checks the source code for potential violations of ANSI aliasing rules and disables unsafe optimizations related to the code for those statements that are identified as potential violations.

- **High-level optimizations (HLO):** Enable HLO with option `O3`. This enables additional loop optimizations that make it easier for the compiler to vectorize the transformed loops. The HLO report, obtained using the `[Q]opt-report-phase[:]loop` option or the corresponding IDE selection, tells you if some of these additional transformations occurred.

Vectorization and Loops

This topic provides more information on the interaction between the auto-vectorizer and loops.

Interactions with Loop Parallelization

Combine the [Q]parallel and [Q]x options to instruct the Intel® C++ Compiler to attempt both Automatic Parallelization and automatic loop vectorization in the same compilation.

NOTE
Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

NOTE
This option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

In most cases, the compiler will consider outermost loops for parallelization and innermost loops for vectorization. If deemed profitable, however, the compiler may even apply loop parallelization and vectorization to the same loop.

See Programming with Auto-parallelization and Programming Guidelines for Vectorization.

In some rare cases, a successful loop parallelization (either automatically or by means of OpenMP directives) may affect the messages reported by the compiler for a non-vectorizable loop in a non-intuitive way; for example, in the cases where the `/Qopt-report:2 /Qopt-report-phase:vec` (Windows) or `-qopt-report=2 -qopt-report-phase=vec` (Linux and macOS) options indicate that loops were not successfully vectorized.

Types of Vectorized Loops

For integer loops, the 128-bit Intel® Streaming SIMD Extensions (Intel® SSE) and the Intel® Advanced Vector Extensions (Intel® AVX) provide SIMD instructions for most arithmetic and logical operators on 32-bit, 16-bit, and 8-bit integer data types, with limited support for the 64-bit integer data type.

Vectorization may proceed if the final precision of integer wrap-around arithmetic is preserved. A 32-bit shift-right operator, for instance, is not vectorized in 16-bit mode if the final stored value is a 16-bit integer. Also, note that because the Intel® SSE and the Intel® AVX instruction sets are not fully orthogonal (shifts on byte operands, for instance, are not supported), not all integer operations can actually be vectorized.

For loops that operate on 32-bit single-precision and 64-bit double-precision floating-point numbers, Intel® SSE provides SIMD instructions for the following arithmetic operators:

- Addition (+)
- Subtraction (-)
- Multiplication (*)
- Division (/)

Additionally, Intel® SSE provide SIMD instructions for the binary `MIN` and `MAX` and unary `SQRT` operators. SIMD versions of several other mathematical operators (like the trigonometric functions `SIN`, `COS`, and `TAN`) are supported in software in a vector mathematical run-time library that is provided with the compiler.

To be vectorizable, loops must be:

- **Countable:** The loop trip count must be known at entry to the loop at runtime, though it need not be known at compile time (that is, the trip count can be a variable but the variable must remain constant for the duration of the loop). This implies that exit from the loop must not be data-dependent.
- **Single entry and single exit:** as is implied by stating that the loop must be countable. Consider the following example of a loop that is not vectorizable, due to a second, data-dependent exit:

```
void no_vec(float a[], float b[], float c[]){
  int i = 0.;
  while (i < 100) {
    a[i] = b[i] * c[i];
    //  this is a data-dependent exit condition:
    if (a[i] < 0.0)
    break;
    ++i;
  }
}
```

  Which results in the following message when the code is compiled:

```
> icc -c -O2 -qopt-report=2 -qopt-report-phase=vec two_exits.cpp
two_exits.cpp(4) (col. 9): remark: loop was not vectorized: nonstandard loop is not a
vectorization candidate.
```

- **Contain straight-line code:** SIMD instruction perform the same operation on data elements from multiple iterations of the original loop, therefore, it is not possible for different iterations to have different control flow; that is, they must not branch. It follows that `switch` statements are not allowed. However, `if` statements are allowed if they can be implemented as masked assignments, which is usually the case. The calculation is performed for all data elements but the result is stored only for those elements for which the mask evaluates to true. Consider the following example that may be vectorized:

```
#include <math.h>
void quad(int length, float *a, float *b, float *c, float *restrict x1, float *restrict x2) {
  for (int i=0; i<length; i++) {
    float s = b[i]*b[i] - 4*a[i]*c[i];
    if ( s >= 0 ) {
      s = sqrt(s) ;
      x2[i] = (-b[i]+s)/(2.*a[i]);
```

```
      x1[i] = (-b[i]-s)/(2.*a[i]);
    } else {
      x2[i] = 0.;
      x1[i] = 0.;
    }
  }
}
```

Which results in the following message when the code is compiled:

```
> icc -c -restrict -qopt-report=2 -qopt-report-phase=vec quad.cpp
quad5.cpp(5) (col. 3): remark: LOOP WAS VECTORIZED.
```

- **Innermost loop of a nest:** The only exception is if an original outer loop is transformed into an inner loop as a result of some other prior optimization phase, such as unrolling, loop collapsing or interchange, or an original outermost loop is transformed to an innermost loop due to loop materialization.
- **Without function calls:** Even a `print` statement is sufficient to prevent a loop from getting vectorized. The vectorization report message is typically: non-standard loop is not a vectorization candidate. The two major exceptions are for intrinsic math functions and for functions that may be inlined.

Intrinsic math functions are allowed, because the compiler runtime library contains vectorized versions of these functions. See below for a list of these functions; most exist in both float and double versions:

- `acos`
- `acosh`
- `asin`
- `asinh`
- `atan`
- `atan2`
- `atanh`
- `cbrt`
- `ceil`
- `cos`
- `cosh`
- `erf`
- `erfc`
- `erfinv`
- `exp`
- `exp2`
- `fabs`
- `floor`
- `fmax`
- `fmin`
- `log`
- `log2`
- `log10`
- `pow`
- `round`
- `sin`
- `sinh`
- `sqrt`
- `tan`
- `tanh`
- `trunc`

The loop in the following example may be vectorized because `sqrt()` is vectorizable and `func()` gets inlined. Inlining is enabled at default optimization for functions in the same source file. An inlining report may be obtained by setting the options `/Qopt-report:2 /Qopt-report-phase:ipo` (Windows) or `-qopt-report=2 -qopt-report-phase=ipo` (Linux).

```
float func(float x, float y, float xp, float yp) {
  float denom;
  denom = (x-xp)*(x-xp) + (y-yp)*(y-yp);
  denom = 1./sqrtf(denom);
  return denom;
}

float trap_int(float y, float x0, float xn, int nx, float xp, float yp) {
  float x, h, sumx;
  int i;
  h = (xn-x0) / nx;
  sumx = 0.5*( func(x0,y,xp,yp) + func(xn,y,xp,yp) );
  for (i=1;i<nx;i++) {
    x = x0 + i*h;
    sumx = sumx + func(x,y,xp,yp);
  }
  sumx = sumx * h;
  return sumx;
}
```

Which results in the following message when the code is compiled:

```
> icc -c -qopt-report=2 -qopt-report-phase=vec trap_integ.c
trap_int.c(16) (col. 3): remark: LOOP WAS VECTORIZED.
```

Statements in the Loop Body

The vectorizable operations are different for floating-point and integer data.

Integer Array Operations

The statements within the loop body may contain *char*, *unsigned char*, *short*, *unsigned short*, *int*, and *unsigned int*. Calls to functions such as `sqrt` and `fabs` are also supported. Arithmetic operations are limited to addition, subtraction, bitwise `AND`, `OR`, and `XOR` operators, division (via run-time library call), multiplication, `min`, and `max`. You can mix data types but this may potentially cost you in terms of lowering efficiency. Some example operators where you can mix data types are multiplication, shift, or unary operators.

Other Operations

No statements other than the preceding floating-point and integer operations are allowed. In particular, note that the special `__m64__m128`, and `__m256` data types are not vectorizable. The loop body cannot contain any function calls. Use of Intel® SSE intrinsics (for example, `_mm_add_ps`) or Intel® AVX intrinsics (for example, `_mm256_add_ps`) are not allowed.

Loop Constructs

Loops can be formed with the usual `for` and `while` constructs. Loops must have a single entry and a single exit to be vectorized. The following examples illustrate loop constructs that can and cannot be vectorized. The non-vectorizable structure example shows a loop that cannot be vectorized because of the inherent potential for an early exit from the loop.

Vectorizable structure:

```
void vec(float a[], float b[], float c[]) {
  int i = 0;
  while (i < 100) {
// The if branch is inside body of loop.
    a[i] = b[i] * c[i];
    if (a[i] < 0.0)
        a[i] = 0.0;
        i++;
  }
}
```

Non-vectorizable structure:

```
void no_vec(float a[], float b[], float c[]) {
  int i = 0;
  while (i < 100) {
    if (a[i] < 50)
// The next statement is a second exit
// that allows an early exit from the loop.
      break;
    ++i;
  }
}
```

Loop Exit Conditions

Loop exit conditions determine the number of iterations a loop executes. For example, fixed indexes for loops determine the iterations. The loop iterations must be countable and the number of iterations must be expressed as one of the following:

- A constant.
- A loop invariant term.
- A linear function of outermost loop indices.

In the case where a loops exit depends on computation, the loops are not countable. The examples below show loop constructs that are countable and non-countable. The non-countable loop example demonstrates a loop construct that is non-countable due to dependency loop variant count value.

Countable loop, example one:

```
void cnt1(float a[], float b[], float c[],
          int n, int lb) {
// Exit condition specified by "N-1b+1"
  int cnt=n, i=0;
  while (cnt >= lb) {
```

```
// lb is not affected within loop.
    a[i] = b[i] * c[i];
    cnt--;
    i++;
  }
}
```

Countable loop, example two:

```
void vec(float a[], float b[], float c[]) {
  int i = 0;
  while (i < 100) {
// The if branch is inside body of loop.
    a[i] = b[i] * c[i];
    if (a[i] < 0.0)
        a[i] = 0.0;
        i++;
  }
}
```

Non-countable loop:

```
void no_cnt(float a[], float b[], float c[]) {
  int i=0;
// Iterations dependent on a[i].
  while (a[i]>0.0) {
    a[i] = b[i] * c[i];
    i++;
  }
}
```

Strip-mining and Cleanup

Strip-mining, also known as loop sectioning, is a loop transformation technique for enabling SIMD-encoding of loops, as well as a means of improving memory performance. By fragmenting a large loop into smaller segments or strips, this technique transforms the loop structure in two ways:

- By increasing the temporal and spatial locality in the data cache if the data is reusable in different passes of an algorithm.
- By reducing the number of iterations of the loop by a factor of the length of each vector, or number of operations being performed per SIMD operation. With the Intel® Streaming SIMD Extensions (Intel® SSE), the vector or strip-length is reduced by four times: four floating-point data items per single Intel® SSE single-precision floating-point SIMD operation are processed.

First introduced for vectorizers, this technique consists of the generation of code when each vector operation is done for a size less than or equal to the maximum vector length on a given vector machine.

The compiler automatically strip-mines your loop and generates a cleanup loop. For example, assume the compiler attempts to strip-mine the loop before vectorization. After vectorization, the compiler might handle the strip mining and loop cleaning by restructuring the loop.

Before vectorization:

```
i=0;
while(i<n) {
  // Original loop code
  a[i]=b[i]+c[i];
  ++i;
}
```

After vectorization:

```
// The vectorizer generates the following two loops
i=0;
while(i<(n-n%4)) {
  // Vector strip-mined loop
  // Subscript [i:i+3] denotes SIMD execution
  a[i:i+3]=b[i:i+3]+c[i:i+3];
  i=i+4;
}
while(i<n) {
  // Scalar clean-up loop
  a[i]=b[i]+c[i];
  ++i;
}
```

Loop Blocking

It is possible to treat loop blocking as strip-mining in two or more dimensions. Loop blocking is a useful technique for memory performance optimization. The main purpose of loop blocking is to eliminate as many cache misses as possible. This technique transforms the memory domain into smaller chunks rather than sequentially traversing through the entire memory domain. Each chunk should be small enough to fit all the data for a given computation into the cache, maximizing data reuse.

Consider the following example, loop blocking allows arrays *A* and *B* to be blocked into smaller rectangular chunks so that the total combined size of two blocked (*A* and *B*) chunks is smaller than cache size, which can improve data reuse.

The transformed loop after blocking example illustrates loop blocking the `add` function (from the original loop example). In order to benefit from this optimization, you might have to increase the cache size.

Original loop:

```
#include <time.h>
#include <stdio.h>
#define MAX 7000

void add(int a[][MAX], int b[][MAX]);
int main() {
int i, j;
int A[MAX][MAX];
int B[MAX][MAX];
time_t start, elaspe;
int sec;

//Initialize array
for(i=0;i<MAX;i++) {
  for(j=0;j<MAX; j++) {
    A[i][j]=j;
    B[i][j]=j;
  }
}

 start= time(NULL);
 add(A, B);
 elaspe=time(NULL);
 sec = elaspe - start;
 printf("Time %d",sec); //List time taken to complete add function
}
```

```
void add(int a[][MAX], int b[][MAX]) {
 int i, j;
 for(i=0;i<MAX;i++) {
  for(j=0; j<MAX;j++ {
     a[i][j] = a[i][j] + b[j][i]; //Adds two matrices
    }
  }
}
```

Transformed loop after blocking:

```
#include <stdio.h>
#include <time.h>
#define MAX 7000
void add(int a[][MAX], int b[][MAX]);

int main() {
  #define BS 8  //Block size is selected as the loop-blocking factor.
  int i, j;
  int A[MAX][MAX];
  int B[MAX][MAX];
  time_t start, elaspe;
  int sec;

//initialize array
for(i=0;i<MAX;i++) {
  for(j=0;j<MAX;j++) {
    A[i][j]=j;
    B[i][j]=j;
  }
}
start= time(NULL);

add(A, B);
elapse=time(NULL);
sec = elapse - start;
printf("Time %d",sec); //Display time taken to complete loopBlocking function
}

void add(int a[][MAX], int b[][MAX]) {
  int i, j, ii, jj;
  for(i=0;i<MAX;i+=BS) {
   for(j=0; j<MAX;j+=BS) {
     for(ii=i; ii<i+BS; ii++) {   //outer loop
       for(jj=j;jj<j+BS; jj++) {  //Array B experiences one cache miss
                                  //for every iteration of outer loop
         a[ii][jj] = a[ii][jj] + b[jj][ii]; //Add the two arrays
        }
      }
    }
  }
}
```

Loop Interchange and Subscripts with Matrix Multiply

Loop interchange is often used for improving memory access patterns. Matrix multiplication is commonly written as shown in the typical matrix multiplication example.

The use of *B*(*K*,*J*) is not a stride-1 reference and therefore will not be vectorized efficiently.

If the loops are interchanged, all the references become stride-1 as shown in the matrix multiplication with stride-1 example.

Typical matrix multiplication:

```
void matmul_slow(float *a[], float *b[], float *c[]) {
  int N = 100;
  for (int i = 0; i < N; i++)
    for (int j = 0; j < N; j++)
      for (int k = 0; k < N; k++)
        c[i][j] = c[i][j] + a[i][k] * b[k][j];
}
```

Matrix multiplication with stride-1:

```
void matmul_fast(float *a[], float *b[], float *c[]) {
  int N = 100;
  for (int i = 0; i < N; i++)
    for (int k = 0; k < N; k++)
      for (int j = 0; j < N; j++)
        c[i][j] = c[i][j] + a[i][k] * b[k][j];
}
```

Interchanging is not always possible because of dependencies, which can lead to different results.

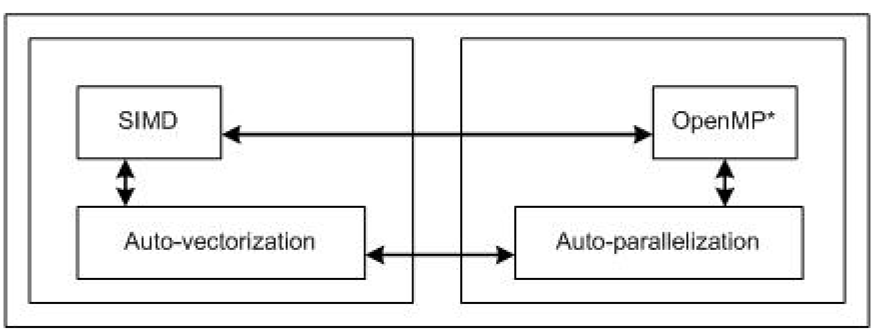
Explicit Vector Programming

This section contains information about explicit vector programming.

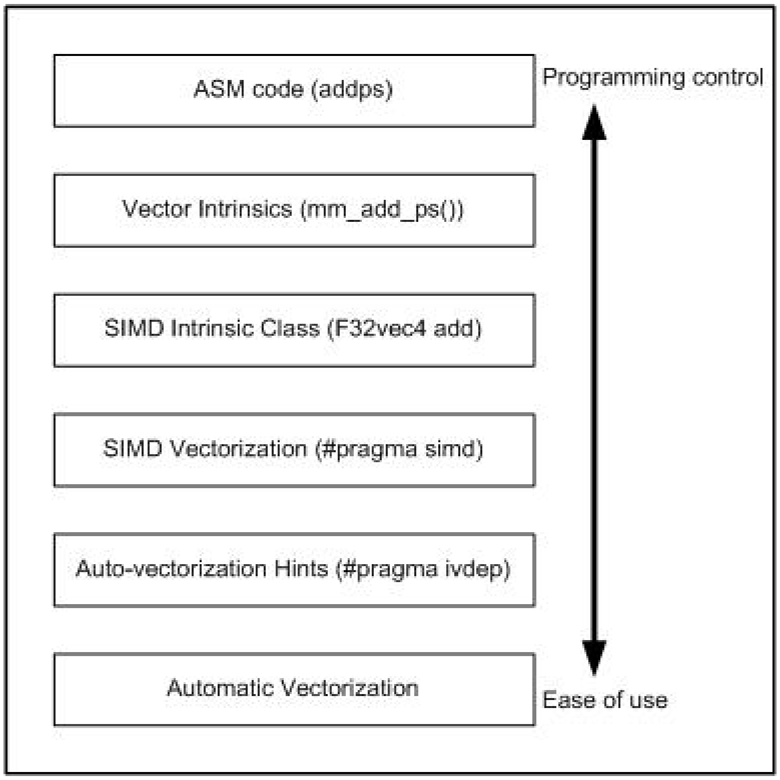
User-mandated or SIMD Vectorization

User-mandated or SIMD vectorization supplements automatic vectorization just like OpenMP parallelization supplements automatic parallelization. The following figure illustrates this relationship. User-mandated vectorization is implemented as a single-instruction-multiple-data (SIMD) feature and is referred to as SIMD vectorization.

NOTE
The SIMD vectorization feature is available for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.



The following figure illustrates how SIMD vectorization is positioned among various approaches that you can take to generate vector code that exploits vector hardware capabilities. The programs written with SIMD vectorization are very similar to those written using auto-vectorization hints. You can use SIMD vectorization to minimize the number of code changes that you may have to go through in order to obtain vectorized code.



SIMD vectorization uses the `#pragma omp simd` pragma to effect loop vectorization. You must add this pragma to a loop and recompile to vectorize the loop using the option `-qopenmp-simd` (Linux and macOS) or `Qopenmp-simd` (Windows).

Consider an example in C++ where the function `add_floats()` uses too many unknown pointers for the compiler's automatic runtime independence check optimization to kick in. You can give a data dependence assertion using the auto-vectorization hint via `#pragma ivdep` and let the compiler decide whether the auto-vectorization optimization should be applied to the loop. Or you can now enforce vectorization of this loop by using `#pragma omp simd` .

Vectorization without #pragma omp simd:

```
[D:/simd] cat example1.c
void add_floats(float *a, float *b, float *c, float *d, float *e, int n) {
 int i;
 for (i=0; i<n; i++){
  a[i] = a[i] + b[i] + c[i] + d[i] + e[i];
 }
}
```

```
[D:/simd] icl -nologo -c -Qopt-report2 -Qopt-report-file=stderr -Qopt-report-phase=vec -Qopenmp-simd example1.c
example1.c

Begin optimization report for: add_floats(float *, float *, float *, float *, float *, int)

    Report from: Vector optimizations [vec]

LOOP BEGIN at C:\Users\test\run\example1.c(3,2)
```

```
   remark #15344: loop was not vectorized: vector dependence prevents vectorization. First
dependence is shown below. Use level 5 report for details
   remark #15346: vector dependence: assumed FLOW dependence between a[i] (4:3) and b[i] (4:3)
LOOP END

LOOP BEGIN at C:\Users\test\run\example1.c(3,2)
<Remainder>
LOOP END
===========================================================================
```

Vectorization with #pragma omp simd:

```
[D:/simd] cat example1.c
void add_floats(float *a, float *b, float *c, float *d, float *e, int n) {
    int i;
    #pragma omp simd
    for (i=0; i<n; i++){
        a[i] = a[i] + b[i] + c[i] + d[i] + e[i];
        }
}
```

```
[D:/simd] icl -nologo -c -Qopt-report2 -Qopt-report-file=stderr -Qopt-report-phase=vec -Qopenmp-
simd example1.c
example1.c

Begin optimization report for: add_floats(float *, float *, float *, float *, float *, int)

    Report from: Vector optimizations [vec]

LOOP BEGIN at C:\iUsers\test\run\example1.c(4,2)
<Peeled loop for vectorization>
LOOP END

LOOP BEGIN at C:\iUsers\test\run\example1.c(4,2)
   remark #15301: OpenMP SIMD LOOP WAS VECTORIZED
LOOP END

LOOP BEGIN at C:\iUsers\test\run\example1.c(4,2)
<Alternate Alignment Vectorized Loop>
LOOP END

LOOP BEGIN at C:\iUsers\test\run\example1.c(4,2)
<Remainder loop for vectorization>
   remark #15301: REMAINDER LOOP WAS VECTORIZED
LOOP END

LOOP BEGIN at C:\iUsers\test\run\example1.c(4,2)
<Remainder loop for vectorization>
LOOP END
===========================================================================
```

The difference between using `#pragma omp simd` and auto-vectorization hints is that with `#pragma omp simd`, the compiler generates a warning when it is unable to vectorize the loop. With auto-vectorization hints, actual vectorization is still under the discretion of the compiler, even when you use the `#pragma vector always` hint.

`#pragma omp simd` has optional clauses to guide the compiler on how vectorization must proceed. Use these clauses appropriately so that the compiler obtains enough information to generate correct vector code. For more information on the clauses, see the `#pragma omp simd` description.

Additional Semantics

Note the following points when using the omp simd pragma.

- A variable may belong to zero or one of the following: private, linear, or reduction.
- Within the vector loop, an expression is evaluated as a vector value if it is private, linear, reduction, or it has a sub-expression that is evaluated to a vector value. Otherwise, it is evaluated as a scalar value (that is, broadcast the same value to all iterations). Scalar value does not necessarily mean loop invariant, although that is the most frequently seen usage pattern of scalar value.
- A vector value may not be assigned to a scalar L-value. It is an error.
- A scalar L-value may not be assigned under a vector condition. It is an error.
- The `switch` statement is not supported.

NOTE
You may find it difficult to describe vector semantics using the SIMD pragma for some auto-vectorizable loops. One example is `MIN`/`MAX` reduction in C since the language does not have `MIN`/`MAX` operators.

Using `vector` Declaration

Consider the following C++ example code with a loop containing the math function, `sinf()`.

NOTE All code examples in this section are applicable for C/C++ on Windows only.

Loop Where the Math Function Is Auto-vectorized

```
[D:/simd] cat example2.c
void vsin(float *restrict a, float *restrict b, int n) {
int i;
for (i=0; i<n; i++) {
  a[i] = sinf(b[i]);
  }
}
```

```
[D:/simd] icl -nologo -c -Qrestrict -Qopt-report2 -Qopt-report-file=stderr -Qopt-report-
phase=vec example2.c
example2.c

Begin optimization report for: vsin(float *restrict, float *restrict, int)

    Report from: Vector optimizations [vec]

LOOP BEGIN at C:\Users\test\run\example2.c(3,1)
<Peeled loop for vectorization>
LOOP END

LOOP BEGIN at C:\Users\test\run\example2.c(3,1)
   remark #15300: LOOP WAS VECTORIZED
LOOP END

LOOP BEGIN at C:\Users\test\run\example2.c(3,1)
<Alternate Alignment Vectorized Loop>
LOOP END

LOOP BEGIN at C:\Users\test\run\example2.c(3,1)
```

```
<Remainder loop for vectorization>
LOOP END
===========================================================================
```

When you compile the above code, the loop with `sinf()` function is auto-vectorized using the appropriate Short Vector Math Library (SVML) library function provided by the Intel® C++ Compiler. The auto-vectorizer identifies the entry points, matches up the scalar math library function to the SVML function, and invokes it.

However, within this loop if you have a call to your function, `foo()`, that has the same prototype as `sinf()`, the auto-vectorizer fails to vectorize the loop because it does not know what `foo()` does unless it is inlined to this call site.

Loop With User-Defined Function Is Not Auto-vectorized

```
[D:/simd] cat example2.c
float foo(float);
void vfoo(float *restrict a, float *restrict b, int n){
    int i;
    for (i=0; i<n; i++){
        a[i] = foo(b[i]);
        }
}
```

```
[D:/simd] icl -nologo -c -Qrestrict -Qopt-report2 -Qopt-report-file=stderr -Qopt-report-
phase=vec example2.c
example2.c

Begin optimization report for: vsin(float *restrict, float *restrict, int)

    Report from: Vector optimizations [vec]

Non-optimizable loops:

LOOP BEGIN at C:\Users\test\run\example2.c(3,1)
   remark #15543: loop was not vectorized: loop with function call not considered an
optimization candidate.
LOOP END
```

In such cases, you can use the `__declspec(vector)` (Windows) or `__attribute__((vector))` (Linux) declaration to vectorize the loop. All you need to do is add the `vector` declaration to the function declaration, and recompile both the caller and callee code, and the loop and function are vectorized.

Loop with User-Defined Function with SIMD Declaration Is Vectorized

```
[D:/simd] cat example3.c
// foo() and vfoo() do not have to be in the same compilation unit as long
// as both see the same "#pragma omp declare simd" lines.
#pragma omp declare simd
float foo(float);
void vfoo(float *restrict a, float *restrict b, int n){
    int i;
    for (i=0; i<n; i++) { a[i] = foo(b[i]); }
}

float foo(float x) { ... }
```

```
[D:/simd] bash-3.2$ icl -nologo -c -Qopenmp-simd -Qrestrict -Qopt-report1 -Qopt-report-
file=stderr -Qopt-report-phase=vec example3.c
example3.c
```

```
Begin optimization report for: vfoo(float *restrict, float *restrict, int)

    Report from: Vector optimizations [vec]

LOOP BEGIN at C:\Users\test\run\example3.c(7,5)
<Peeled loop for vectorization>
LOOP END

LOOP BEGIN at C:\Users\test\run\example3.c(7,5)
   remark #15300: LOOP WAS VECTORIZED
LOOP END

LOOP BEGIN at C:\Users\test\run\example3.c(7,5)
<Alternate Alignment Vectorized Loop>
LOOP END

LOOP BEGIN at C:\Users\test\run\example3.c(7,5)
<Remainder loop for vectorization>
LOOP END
===========================================================================

Begin optimization report for: foo.._simdsimd3__xmm4nv(float)

    Report from: Vector optimizations [vec]

remark #15347: FUNCTION WAS VECTORIZED with xmm, simdlen=4, unmasked, formal parameter types:
(vector)
===========================================================================

    Report from: Vector optimizations [vec]

remark #15347: FUNCTION WAS VECTORIZED with xmm, simdlen=4, masked, formal parameter types:
(vector)
===========================================================================
```

Restrictions on Using a #pragma omp declare simd Declaration

Vectorization depends on two major factors: hardware and the style of source code. When using the vector declaration, the following features are not allowed:

- Thread creation and joining through , OpenMP `parallel/for/sections/task/target/teams`, and explicit threading API calls.
- Locks, barriers, atomic construct, critical sections (These are allowed inside `#pragma omp ordered simd` blocks).
- Inline ASM code, VM, and Vector Intrinsics (for example, SVML intrinsics).
- Using setjmp, longjmp, SHE and computed `GOTO`.
- EH is not allowed and all vector functions are considered noexcept.
- The `switch` statement (in some cases this may be supported and converted to `if` statements, but this is not reliable).
- The `exit()/abort()` calls.

Non-vector function calls are generally allowed within vector functions but calls to such functions are serialized lane-by-lane and so might perform poorly. Also for SIMD-enabled functions it is not allowed to have side effects except writes by their arguments. This rule can be violated by non-vector function calls, so be careful executing such calls in SIMD-enabled functions.

Formal parameters must be of the following data types:

- (un)signed 8, 16, 32, or 64-bit integer
- 32- or 64-bit floating point
- 64- or 128-bit complex
- A pointer (C++ reference is considered a pointer data type)

Function Annotations and the SIMD Directive for Vectorization

SIMD-enabled Functions

SIMD-enabled functions (formerly called elemental functions) are a general language construct to express a data parallel algorithm. A SIMD-enabled function is written as a regular C/C++ function, and the algorithm describes the operation on one element, using scalar syntax. The function can then be called as a regular C/C++ function to operate on a single element or it can be called in a data parallel context to operate on many elements.

If you are using SIMD-enabled functions and need to link a compiler object file with an object file from a previous version of the compiler (for example, 13.1), you need to use the `[Q]vecabi` compiler option, specifying the `legacy` keyword.

How SIMD-enabled Functions Work

When you write a SIMD-enabled function, the compiler generates short vector variants of the function that you requested, which can perform your function's operation on multiple arguments in a single invocation. The short vector variant may be able to perform multiple operations as fast as the regular implementation performs a single one by using the vector instruction set architecture (ISA) in the CPU. When a call to a SIMD-enabled function occurs in a SIMD loop or another SIMD-enabled function, the compiler replaces the scalar call with the best fit from the available short-vector variants of the function.

In addition, when invoked from a `pragma omp` construct, the compiler may assign different copies of the SIMD-enabled functions to different threads (or workers), executing them concurrently. The result is that your data parallel operation executes on the CPU using both the parallelism available in the multiple cores and the parallelism available in the vector ISA. In other words, if the short vector function is called inside a parallel loop, (a vectorized auto-parallelized loop) you can achieve both vector-level and thread-level parallelism.

Declare a SIMD-enabled Function

You need to use the appropriate syntax from below in your code for the compiler to generate the short vector function:

Linux and macOS

Use the `__attribute__((vector (clauses)))` declaration:

```
__attribute__((vector (clauses))) return_typesimd_enabled_function_name(parameters)
```

Alternately, you can use the following OpenMP pragma, which requires the `[q or Q]openmp` or `[q or Q]openmp-simd` compiler option:

```
#pragma omp declare simd clauses
```

Windows

Use the `__declspec(vector (clauses))` declaration:

```
__declspec(vector (clauses)) return_type simd_enabled_function_name(parameters)
```

The clauses in the vector declaration may be used for achieving better performance by overriding defaults. These clauses at SIMD-enabled function definition declare one or several short vector variants for a SIMD-enabled function. Multiple vector declarations with different set of clauses may be attached to one function in order to declare multiple different short vector variants available for a SIMD-enabled function.

The clauses are defined as follows:

Clause	Definition
processor(cpuid)	Tells the compiler to generate a vector variant using the instructions, the caller/callee interface, and the default vector length selection scheme suitable to the specified processor. Use of this clause is highly recommended, especially for processors with wider vector register support (example: `core_2nd_gen_avx` and newer). `cpuid` takes one of the following values: • `core_4th_gen_avx_tsx` • `core_4th_gen_avx` • `core_3rd_gen_avx` • `core_2nd_gen_avx` • `core_aes_pclmulqdq` • `core_i7_sse4_2` • `atom` • `core_2_duo_sse4_1` • `core_2_duo_ssse3` • `pentium_4_sse3` • `pentium_m` • `pentium_4` • `haswell` • `broadwell` • `skylake` • `skylake_avx512` • `knl` • `knm`
vectorlength(n) / *simdlen(n)* (for `omp declare simd`)	Where `n` is a vector length that is a power of 2, no greater than 32. The *simdlen* clause tells the compiler that each routine invocation at the call site should execute the computation equivalent to `n` times the scalar function execution. When omitted the compiler selects the vector length automatically depending on the routine return value, parameters, and/or the processor clause. When multiple vector variants are called from one vectorization context (for example,

<table>
<tr><th>Clause</th><th>Definition</th></tr>
<tr><td></td><td>two different functions called from the same vector loop), explicit use of identical simdlen values are advised to achieve good performance.</td></tr>
<tr><td>linear(list_item[, list_item...]), where list_item is one of:
param[:step]
val(param[:step])
ref(param[:step])
uval(param[:step])</td><td> The linear clause tells the compiler that for each consecutive invocation of the routine in a serial execution, the value of param is incremented by step, where param is a formal parameter of the specified function or the C++ keyword this. The linear clause can be used on parameters that are either scalar (non-arrays and of non-structured types), pointers, or C++ references. step is a compile-time integer constant expression, which defaults to 1 if omitted. If more than one step is specified for a particular parameter, a compile-time error occurs. Multiple linear clauses will be merged as a union. The meaning of each variant of the clause is as follows: linear(param[:step]): For parameters that are not C++ references: the clause tells the compiler that on each iteration of the loop from which the routine is called the value of the parameter will be incremented by step. The clause can also be used for C++ references for backward compatibility, but it is not recommended.
linear(val(param[:step])): For parameters that are C++ references: the clause tells the compiler that on each iteration of the loop from which the routine is called the referenced value of the parameter will be incremented by step.
linear(uval(param[:step])): For C++ references: means the same as linear(val()). It differs from linear(val()) so if linear(val()) a vector of references is passed to vector variant of the routine but in case of linear(uval()) only one reference is passed (and thus linear(uval()) is better to use in terms of performance).
linear(ref(param[:step])) :For C++ references: means that the reference itself is linear, i.e. the referenced values (that form a vector for calculations) are located sequentially, like in array with the distance between elements equal to step.</td></tr>
<tr><td>uniform(param [, param,]…)</td><td>Where param is a formal parameter of the specified function or the C++ keyword this.</td></tr>
</table>

Clause	Definition
	The *uniform* clause tells the compiler that the values of the specified arguments can be broadcast to all iterations as a performance optimization. It is often useful in generating more favorable vector memory references. An acknowledgment of a *uniform* clause may allow broadcast operations to be hoisted out of the caller loop. Evaluate carefully the performance implications. Multiple uniform clauses are merged as a union.
mask / nomask	The *mask* and *nomask* clauses tell the compiler to generate only masked or unmasked (respectively) vector variants of the routine. When omitted, both masked and unmasked variants are generated. The masked variant is used when the routine is called conditionally.
inbranch / notinbranch	The *inbranch* and *notinbranch* clauses are used with `#pragma omp declare simd`. The *inbranch* clause works the same as the *mask* clause above and the *notinbranch* clause works the same as the *nomask* clause above.

Write the code inside your function using existing C/C++ syntax and relevant built-in functions (see the section on `__intel_simd_lane()` below).

Usage of Vector Function Specifications

You may define several vector variants for one routine with each variant reflecting a possible usage of the routine. Encountering a call, the compiler matches vector variants with actual parameter kinds and chooses the best match. Matching is done by priorities. In other words, if an actual parameter is the loop invariant and the `uniform` clause was specified for the corresponding formal parameter, then the variant with the `uniform` clause has a higher priority. Linear specifications have the following order, from high priority to low: `linear(uval())`, `linear()`, `linear(val())`, `linear(ref())`. Consider the following example loops with the calls to the same routine.

```
// routine prototype
#pragma omp declare simd                           // universal but slowest definition matches
the use in all three loops
#pragma omp declare simd linear(in1) linear(ref(in2)) uniform(mul) // matches the use in the
first loop
#pragma omp declare simd linear(ref(in2))                             // matches the use in the
second and the third loops
#pragma omp declare simd linear(ref(in2)) linear(mul)              // matches the use in the
second loop
#pragma omp declare simd linear(val(in2:2))                           // matches the use in the
third loop
extern int func(int* in1, int& in2, int mul);

int *a, *b, mul, *c;
int *ndx, nn;
...
// loop examples
   for (int i = 0; i < nn; i++) {
       c[i] = func(a + i, *(b + i), mul); // in the loop, the first parameter is changed
```

```
linearly,
                                          // the second reference is changed linearly too
                                          // the third parameter is not changed
   }

   for (int i = 0; i < nn; i++) {
       c[i] = func(&a[ndx[i]], b[i], i + 1); // the value of the first parameter is
unpredictable,
                                             // the second reference is changed linearly
                                             // the third parameter is changed linearly
   }

   #pragma omp simd
   for (int i = 0; i < nn; i++) {
       int k = i * 2;  // during vectorization, private variables are transformed into arrays: k-
>k_vec[vector_length]
       c[i] = func(&a[ndx[i]], k, b[i]); // the value of the first parameter is unpredictable,
                                         // the second reference and value can be considered
linear
                                         // the third parameter has unpredictable value
                                         // (the #pragma simd linear(val(in2:2))) will be chosen
from the two matching variants)
  }
```

SIMD-enabled Functions and C++

You should use SIMD-enabled functions in modern C++ with caution: C++ imposes strict requirements on compilation and execution environments that may not compose well with semantically-rich language extensions such as SIMD-enabled functions. There are three key aspects of C++ that interrelate with SIMD-enabled functions concept: exception handling, dynamic polymorphism, and the C++ type system.

SIMD-enabled Functions and Exception Handling

Exceptions are currently not supported in SIMD contexts: exceptions cannot be thrown and/or caught in SIMD loops and SIMD-enabled functions. Therefore, all SIMD-enabled functions are considered `noexcept` in C++11 terms. This affects not only short vector variants of a function, but its original scalar routine as well. This is enforced when the function is compiled: it is checked against throw construct and against function calls throwing exceptions. It is also enforced when the SIMD-enabled function call is compiled.

SIMD-enabled Functions and Dynamic Polymorphism

Vector attributes can be applied to virtual functions of classes with some limitations during polymorphic virtual function calls. The syntax of vector declarations is the same as for regular SIMD-enabled class methods: attach vector declarations as described above to the method declarations inside the class declaration.

Vector function attributes for virtual methods are inherited. If a vector attribute is specified for an overriding virtual function, it must match that of the overridden function. Even if the virtual method implementation is overridden in a derived class the vector declarations are inherited and applied. A set of vector variants is produced for the override according to vector variants set on parent. This rule also applies when the parent does not have any vector variants. If a virtual method is introduced as non-SIMD-enabled (no vector declarations supplied), it cannot become SIMD-enabled in the derived class even if the derived class contains its own implementation of the virtual method.

Matching vector variants for a virtual method is done by the declared (static) type of an object for which the method is called. The actual (dynamic) type of an object may either coincide with the static type or be inherited from it.

Unlike regular function calls which transfer control to one target function, the call target of a virtual function depends on the dynamic type of the object for which the method is called and accomplished indirectly via the virtual function table of a class. In a single SIMD chunk, the virtual method may be invoked for objects of multiple classes, for example, elements of a polymorphic collection. This requires multiple calls to different targets within a single SIMD chunk. This works as follows:

1. If a SIMD-enabled virtual function call is matched to a variant with a uniform *this* parameter, multiple calls are not needed. The compiler makes an indirect call to the matched vector variant of a virtual method of the object's dynamic class.
2. If a SIMD-enabled virtual function call is matched to a variant with a non-uniform *this* parameter, all objects in a SIMD chunk may still share virtual method implementation. This is checked and a single, indirect call to the matched vector variant of the target virtual method implementation is invoked.
3. Otherwise, lanes sharing virtual call targets are masked-in and a masked vector variant corresponding to the match is invoked in a loop for each unique virtual call target. If a masked variant is not provided for matching a vector variant and a *this* parameter is not declared uniform, the match will be rejected.

The following example illustrates SIMD-enabled virtual functions:

```
struct Base {
#pragma omp declare simd
#pragma omp declare simd uniform(this)
   virtual int process(int);
};

struct Child1 : Base {
   // int process(int); is inherited
};

struct Child11 : Child1 {
  int process(int); // Overrides implementation, inherits vector declarations
};

struct Child2 : Base {
  int process(int); // Overrides implementation, inherits vector declarations
};

int main() {
    int arr[100];
    Base* c2 = new Child2();
    Base* objs[100];
    int res = 0;

// SIMD-enabled virtual function call for uniform object
#pragma omp simd reduction(+:res)
    for (int i = 0; i < 100; i++) {
      res += c2->process(arr[i]);  // Variant with uniform this is matched
                                   // call to vector variant of
                                   // Child2::process() is invoked
   }

// Initialize polymorphic array of objects
    for (int i = 0; i < 100; i++) {
       if (i % 16 < 4) objs[i] = new Base();
       else if (i % 16 < 8) objs[i] = new Child1();
       else if (i % 12 < 12) objs[i] = new Child11();
       else objs[i] = new Child2();
   }

// SIMD-enabled virtual function call for non-uniform objects
```

```
#pragma omp simd reduction(+:res) simdlen(8)
    for (int i = 0; i < 100; i++) {
       res += objs[i]->process(arr[i]);  // Variant with non-uniform this is
                                         // matched
       // Base and Child1 share the same 'process' implementation, so call
       // targets for each even chunk [i*16:i*16+7] are the same even though
       // this pointers are different for all elements of objs[] array.

       // Odd chunks [i*16+8:i*16+15] consist of objects of classes Child11
       // and Child2 and so require calls to their respective implementations
       // of process() virtual functions. Masked vector variant for
       // Child11::process() is called with mask 0b00001111 (lower lanes of a
       // chunk) and masked vector variant for Child2::process() is called
       // with mask 0b11110000 (upper lanes of a chunk).
   }

   return res;
}
```

The following are limitations to SIMD-enabled virtual function support:

- Multiple inheritance, including virtual inheritance, is not supported for classes having SIMD-enabled virtual methods. This is because calls to virtual functions in multiple inheritance cases may be done through special functions called thunks, which adjust the 'this' pointer and/or virtual function table pointer. The current implementation doesn't support thunks for SIMD-enabled virtual calls because in this case thunks should themselves become SIMD-enabled functions that are not implemented.
- It is not possible to get the address of a SIMD-enabled virtual method. Support of SIMD-enabled virtual functions would require additional information, so their binary representation is different. Such cases will not be handled properly by code expecting a regular pointer to the virtual member.

SIMD-enabled Functions and the C++ Type System

Vector attributes are attributes in the C++11 sense and so are not part of a functional type of SIMD-enabled functions. Vector attributes are bound to the function itself, an instance of a functional type. This has the following implications:

- Template instantiations having SIMD-enabled functions as template parameters won't catch vector attributes, so it is impossible to preserve vector attributes in function wrapper templates like `std::bind` which add indirection. This indirection may sometimes be optimized away by compiler and the resulting direct call will have all vector attributes associated.
- There is no way to overload or specialize templates by vector attributes.
- There is no way to write functional traits to capture vector attributes for the sake of template metaprogramming.

The example below depicts various situations where this situation may be observed:

```
template <int f(int)>   // Function value template - captures exact function
                        // not a function type
int caller1(int x[100]) {
   int res = 0;
#pragma omp simd reduction(+:res)
   for (int i = 0; i < 100; i++) {
      res += f(x[i]);   // Exact function put here upon instantiation
   }
   return res;
}

template <typename F>  // Generic functional type template - captures
                       // object type for functors or entire functional type
```

```
                       // for functions. If vector attributes were part of
                       // a functional type they might be captured and applied
                       // but currently they are not.
int caller2(F f, int x[100]) {
   int res = 0;
#pragma omp simd reduction(+:res)
   for (int i = 0; i < 100; i++) {
      res += f(x[i]);  // Will call matching function 'f' indirectly
                       // Will call matching f.operator() directly
   }
   return res;
}

template <typename RET, typename ARG>  // Type-decomposing template
                                       // captures argument and return types.
                                       // Vector attributes would be lost
                                       // even if they were part of a
                                       // functional type.
int caller3(RET (*f)(ARG), int x[100]) {
   int res = 0;
#pragma omp simd reduction(+:res)
   for (int i = 0; i < 100; i++) {
      res += f(x[i]);  // Will call matching function 'f' indirectly
   }
   return res;
}

#pragma omp declare simd
int function(int x); // SIMD-enabled function
int nv_function(int x);                 // Regular scalar function

struct functor {                        // Functor class with
#pragma omp declare simd                      // SIMD-enabled operator()
   int operator()(int x);
};

int arr[100];

int main() {
   int res;
#pragma noinline
   res = caller1<function>(arr); // This will be instantiated for
                                 // function() and call short vector variant
#pragma noinline
   res += caller1<nv_function>(arr); // This will be separately instantiated
                                     // for nv_function()
#pragma noinline
   res += caller2(function, arr); // This will be instantiated for
                                  // int(*)(int) type and will call scalar
                                  // function() indirectly
#pragma noinline
   res += caller2(nv_function, arr); // This will call the same
                                     // instantiation as above on nv_function

#pragma noinline
   res += caller2(functor(), arr); // This will be instantiated for
                                   // functor type and will call short vector
```

```
                                   // variant of functor::operator()
#pragma noinline
   res += caller3(function, arr); // This will be instantiated for
                                  // <int, int> types and will call scalar
                                  // function() indirectly
#pragma noinline
   res += caller3(nv_function, arr); // This will call the same
                                     // instantiation as above on nv_function
   return res;
}
```

NOTE If calls to `caller1`, `caller2` and `caller3` are inlined, the compiler is able to replace indirect calls by direct calls in all cases. In this case `caller2(function, arr)` and `caller3(function, arr)` both call short vector variants of a function as result of the usual replacement of direct calls to function() by matching short vector variants in the SIMD loop.

Invoke a SIMD-enabled Function with Parallel Context

Typically, the invocation of a SIMD-enabled function provides arrays wherever scalar arguments are specified as formal parameters.

The following two invocations will give instruction-level parallelism by having the compiler issue special vector instructions.

```
a[:] = ef_add(b[:],c[:]);    //operates on the whole extent of the arrays a, b, c
```

```
a[0:n:s] = ef_add(b[0:n:s],c[0:n:s]); //use the full array notation construct to also specify n
as an extend and s as a stride
```

NOTE The array notation syntax, as well as calling the SIMD-enabled function from the regular `for` loop, results in invoking the short vector function in each iteration and using the vector parallelism but the invocation is done in a serial loop, without using multiple cores.
Use of array notation syntax and SIMD-enabled functions in a regular `for` loop results in invoking the short vector function in each iteration and using the vector parallelism, but the invocation is done in a serial loop without using multiple cores.

Use the __intel_simd_lane() Built-in Function

When called from within a vectorized loop, the `__intel_simd_lane()` built-in function will return a number between 0 and *vectorlength* - 1 that reflects the current "lane id" within the SIMD vector. `__intel_simd_lane()` will return zero if the loop is not vectorized. Calling `__intel_simd_lane()` outside of an explicit vector programming construct is discouraged. It may prevent auto-vectorization and such a call often results in the function returning zero instead of a value between 0 and *vectorlength*-1.

To see how `__intel_simd_lane()` can be used, consider the following example:

```
void accumulate(float *a, float *b, float *c, d){
  *a+=sin(d);
  *b+=cos(d);
  *c+=log(d);
}
```

```
for (i=low; i<high; i++){
    accumulate(&suma, &sumb, &sumc, d[i]);
}
```

The gather-scatter type memory addressing caused by the references to arrays A, B, and C in the SIMD-enabled function `accumulate()` will significantly hurt performance making the whole conversion useless. To avoid this penalty, you may use the `__intel_simd_lane()` built-in function as follows:

```
#pragma omp declare simd uniform(a,b,c) aligned(a,b,c)
void accumulate(float *a, float *b, float *c, float d){
// No need to take "loop index". No need to know VL.
  a[__intel_simd_lane()]+=sin(d);
  b[__intel_simd_lane()]+=cos(d);
  c[__intel_simd_lane()]+=log(d);
}

#define VL 16 // actual SIMD code may use vectorlength of 4 but it's okay.
float a[VL] = {0.0f};
float b[VL] = {0.0f};
float c[VL] = {0.0f};
#pragma omp simd for simdlen(VL)
for (i=low; i<high; i++){
    // If low is known to be zero at compile time, "i & (VL-1)"
    // would accomplish what __intel_simd_lane() is intended for,
    // but only on the caller side.
    accumulate(a, b, c, d[i]);
}
for(i=0;i<VL;i++){
    suma += a[i];
    sumb += b[i];
    sumc += c[i];
}
```

With the use of `__intel_simd_lane()`, the references to the arrays in `accumulate()` will have unit-stride.

Limitations

The following language constructs are not allowed within SIMD-enabled functions:

- The `GOTO` statement.
- The `switch` statement with 16 or more `case` statements.
- Operations on `classes` and `structs` (other than member selection).
- Any OpenMP construct.

SIMD-enabled Function Pointers

SIMD-enabled functions (formerly called elemental functions) are a general language construct to express a data parallel algorithm. A SIMD-enabled function is written as a regular C/C++ function, and the algorithm within describes the operation on one element, using scalar syntax. The function can then be called as a regular C/C++ function to operate on a single element or it can be called in a data parallel context to operate on many elements.

In some cases it is desirable to have a pointer for SIMD-enabled functions, but without special effort, the vector nature of a function will be lost: function pointers will point to the scalar function and there will be no way to call the short vector variants existing for this scalar function.

In order to support indirect calls to vector variants of SIMD-enabled functions, SIMD-enabled function pointers were introduced. A SIMD-enabled function pointer is a special kind of pointer incompatible with a regular function pointer. They refer to an entire set of short vector variants as well as the scalar function. This incompatibility incurs the risk of inappropriate misuse, especially in C++ code. Therefore vector function pointer support is disabled by default.

To enable support of SIMD-enabled function pointers use the following compiler switches: `Qsimd-function-pointers` on Windows or `simd-function-pointers` on Linux/macOS.

Such pointers may hold the address of a SIMD-enabled function in a way that enables indirect calls to the appropriate vector variants of the function from a SIMD loop or another SIMD-enabled function.

When disabled with `Qsimd-function-pointers-` on Windows or `no-simd-function-pointers` on Linux/macOS vector attributes (`__declspec(vector)` or `__attribute__((vector))` or `#pragma omp declare simd`) can only be placed on function declarations and definitions. Other placements will result in a warning message and then be ignored.

How SIMD-enabled Function Pointers Work

When you write a SIMD-enabled function, the compiler generates short vector variants of the function that you requested, which can perform your function's operation on multiple arguments in a single invocation. The short vector variants may be able to perform multiple operations as fast as the regular implementation performs just one such operation by utilizing the vector instruction set architecture (ISA) in the CPU. When a call to SIMD-enabled function occurs in a SIMD loop or another SIMD-enabled function, the compiler replaces the scalar call with the best fit short vector variant of the function among those available.

Indirect SIMD-enabled function calls are handled similarly, but the set of available variants should be associated with the function pointer variable, not the target function, because actual call targets are unknown at the indirect call. That means all SIMD-enabled functions to be referenced by a SIMD-enabled function pointer should have a set of variants that match the set of variants declared for the pointer.

Declare a SIMD-enabled Function Pointer Variable

In order for the compiler to generate a pointer to a SIMD-enabled function, you need to provide an indication in your code.

Linux and macOS

Use the `__attribute__((vector (clauses)))` attribute, as follows:

```
__attribute__((vector (clauses))) return_type (*function_pointer_name) (parameters)
```

Alternately, you can use OpenMP `#pragma omp declare simd`, which requires the `[q or Q]openmp` or `[q or Q]openmp-simd` compiler option.

Windows

Use the `__declspec(vector (clauses))` attribute, as follows:

```
__declspec(vector (clauses)) return_type (*function_pointer_name) (parameters)
```

The clauses are described in the previous topic on SIMD-enabled functions.

Usage of Vector Function Attributes on Pointers

You may associate several vector attributes with one SIMD-enabled function pointer which reflects all the variants available for the target functions to be called through the pointer. The attributes usually reflect a possible use of the function pointer in the loops. Encountering an indirect call, the compiler matches the vector variants declared on the function pointer with the actual parameter kinds and chooses the best match.

Matching is done exactly the same way as with direct calls (see the previous topic on SIMD-enabled functions). Consider the following example of the declaration of vector function pointers and loops with indirect calls.

```
// pointer declaration
#pragma omp declare simd                           // universal but slowest definition matches
the use in all three loops
#pragma omp declare simd linear(in1) linear(ref(in2)) uniform(mul)   // matches the use in the
first loop
#pragma omp declare simd linear(ref(in2))                            // matches the use in the
second and the third loops
#pragma omp declare simd linear(ref(in2)) linear(mul)                // matches the use in the
second loop
#pragma omp declare simd linear(val(in2:2))                          // matches the use in the
third loop
int (*func)(int* in1, int& in2, int mul);

int *a, *b, mul, *c;
int *ndx, nn;
...
// loop examples
   for (int i = 0; i < nn; i++) {
       c[i] = func(a + i, *(b + i), mul); // in the loop, the first parameter is changed
linearly,
                                          // the second reference is changed linearly too
                                          // the third parameter is not changed
   }

   for (int i = 0; i < nn; i++) {
       c[i] = func(&a[ndx[i]], b[i], i + 1); // the value of the first parameter is
unpredictable,
                                             // the second reference is changed linearly
                                             // the third parameter is changed linearly
   }

   #pragma omp simd
   for (int i = 0; i < nn; i++) {
       int k = i * 2;  // during vectorization, private variables are transformed into arrays: k-
>k_vec[vector_length]
       c[i] = func(&a[ndx[i]], k, b[i]); // the value of the first parameter is unpredictable,
                                         // the second reference and value can be considered
linear
                                         // the third parameter has unpredictable value
                                         // (the __declspec(vector(linear(val(in2:2)))) will be
chosen from the two matching variants)
   }
```

Before any use in a call, the function pointer should be assigned either the address of a function or another function pointer. Just as with function pointers, vector function pointers should be compatible at assignment and initialization. The compatibility rules are described below.

Vector Function Pointer Compatibility

Pointer assignment compatibility is defined as following:

1. If a SIMD-enabled function pointer is assigned the address of a function, the function should be compatible with the pointer in the usual C/C++ sense, it should be SIMD-enabled, and the set of vector variants declared for the function should be a superset of those declared for the pointer. This includes initializations and passing addresses of SIMD-enabled functions as parameters.

2. If a SIMD-enabled function pointer is assigned another function pointer, the source pointer should be compatible with the destination function pointer in the general C/C++ sense, it should be SIMD-enabled, and the set of vector variants declared for the source pointer should be exactly the same as those declared for destination pointer. This includes initializations and passing SIMD-enabled function pointers as parameters.
3. If a regular (non-SIMD-enabled) function pointer is assigned the address of a SIMD-enabled function, the address of a scalar function is assigned. Vector variants cannot be called through the pointer and it cannot be reinterpreted as or converted into a SIMD-enabled function pointer as discussed in rule 2.
4. If a regular (non-SIMD-enabled) function pointer is assigned a SIMD-enabled function pointer matching in the C/C++ sense, the implicit dynamic casting of the right-hand side of the assignment (RHS) is performed by extracting the address of a scalar function and this address is assigned. Vector variants cannot be called through these pointers and it cannot be reinterpreted as or converted into a SIMD-enabled function pointer as discussed in rule 2.

NOTE
SIMD-enabled function pointers and regular function pointers are binary-incompatible and handled differently. Mixing them may lead to severe unpredictable results. The compiler does its best to check compatibility where it is allowed by C/C++ language standards, but in certain cases it cannot check, such as passing function pointers to undeclared functions or as variable arguments. It is best to refrain from using SIMD-enabled function pointers in these contexts. Additional complexities with respect to the C++ type system are described in the *SIMD-enabled Function Pointers and the C++ Type System* section below.

A SIMD-enabled function pointer may be assigned to a scalar function pointer with a cast as described in rule 4 above, but a SIMD-enabled function pointer cannot refer to a scalar function pointer.

```
// pointer declarations
#pragma omp declare simd
int (*ptr1)(int*, int);
#pragma omp declare simd
int (*ptr1a)(int*, int);

#pragma omp declare simd
#pragma omp declare simd linear(a)
typedef int (*fptr_t2)(int* a, int b);

typedef int (*fptr_t3)(int*, int);

fptr_t2 ptr2, ptr2a;
fptr_t3 ptr3;

// function declarations
#pragma omp declare simd
int func1(int* x, int b);

#pragma omp declare simd
#pragma omp declare simd linear(x)
int func2(int* x, int b);

#pragma omp declare simd
#pragma omp declare simd linear(x)
int func3(float* x, int b);

//----------------------------------------
  // allowed assignments
  ptr1 = func1;  // same prototype and vector spec
```

```
  ptr2 = func2;  // same prototype and vector spec
  ptr1a = ptr1;  // same prototype and vector spec
  ptr1a = func2; // same prototype vector spec on function includes all vector spec on pointer

  ptr3 = func1; // scalar pointer with same prototype - use scalar func1
  ptr3 = func2; // scalar pointer with same prototype - use scalar func2
  ptr3 = ptr1;  // scalar pointer with same prototype - implicit conversion from vector to
scalar pointer
  ptr3 = ptr2;  // scalar pointer with same prototype - implicit conversion from vector to
scalar pointer

  // disallowed assignments
  ptr2 = func1; // vector spec on function does not have all specs on pointer
  ptr2 = func3; // prototype mismatch although vector spec matched
  ptr1 = func3; // prototype mismatch although vector spec matched
  ptr3 = func3; // prototype mismatch
  ptr1 = ptr2;  // pointers should have the same vector spec
  ptr2 = ptr3;  // pointers should have the same vector spec
```

Call Sequence

Unlike regular function calls, which transfer control to a target function, the call target of an indirect call depends on the dynamic content of the function pointer. In a loop, call targets may be different on different iterations of a vectorized loop or on different lanes of a SIMD-enabled function executing the call. When vectorized, such an indirect call may involve multiple calls to different targets within a single SIMD chunk. This works as follows:

1. If the vector function pointer is uniform (refer to the OpenMP specification) or if it can be determined to be uniform by the compiler, then multiple calls are not needed. The compiler makes a single indirect call to a matched vector variant accessible by the pointer.
2. If the vector function pointer is not known to be uniform at compile time, all values of the pointer in a SIMD chunk may still be the same. This is checked at run time and a single indirect call to a matched vector variant is invoked.
3. Otherwise, lanes sharing the same function pointer value (call target) are masked-in and a masked vector variant corresponding to the matched one is invoked in the loop for each unique call target. If the masked variant is not provided for the matching vector variant and the function pointer is not proven to be uniform by compiler the match will be rejected and the compiler may serialize the call, or in other words, generate several scalar calls.

```
// pointer typedefs
#pragma omp declare simd
typedef int (*fptr_t1)(int*, int);

// function declarations
#pragma omp declare simd
int func1(int* x, int b);

// uses of vector function pointers
fptr_t1 *fptr_array;   // array of vector function pointers
void foo(int N, int *x, int y){
  fptr_t1 ptr1 = func1;
#pragma omp simd
  for (int i = 0; i < N; i++) {
    ptr1(x+i, y);  // ptr1 is uniform by OpenMP rule.
    fptr_t1 ptr1a = ptr1;
    ptr1a(x+i, y); // compiler can prove ptr1a is uniform.
    fptr_t1 ptr1b = fptr_array[i];
```

```
    ptr1b(x+i,y);  // ptr1b may or may not be uniform.
  }
}
```

SIMD-enabled Function Pointers and the C++ Type System

Use caution when using SIMD-enabled function pointers in modern C++: C++ imposes strict requirements on compilation and execution environments which may not compose well with semantically-rich language extensions such as SIMD-enabled function pointers. Vector specifications on SIMD-enabled function pointers are attributes in C++11 sense and so are not part of a pointer type even though they make that pointer binary incompatible with another pointer of the same type but without the attribute. Vector specifications are not bound to a pointer type, but instead are bound to the variable or function argument (which is an instance of a pointer type) itself. For a given function pointer, the type of the pointer is the same with or without SIMD-enabled function pointer decoration. This has the following important implications:

- Vector attributes put on a function argument are not reflected in C++ name mangling, so the functions differ only in the vector attributes of a functional pointer argument (or lack thereof) will have the same name and will be treated the same by the C++ linker. This may result in a parameter of incorrect vectorness (having the vector attribute or not) being passed into the function. In some cases there is no way for the compiler to detect this situation, so you're strongly encouraged to distinctly name functions having SIMD-enabled function pointers as parameters.
- The incorrect interpretation of function pointers is extremely dangerous because it may lead to the execution of unwanted code or non-code. To identify these situations the compiler issues the following warning if a vector function pointer is used as a C++ function parameter: Warning #3757: this use of a vector function type is not fully supported. If you are sure that no ambiguity is possible—for example, the function accepting the vector function pointer has a distinct name and is fully declared before all uses—you may ignore this warning. Otherwise, ensure that no ambiguity is possible. To prevent such situations the warning can be converted to an error using the command line switch `-diag-error=3757`.
- Template instantiations having SIMD-enabled pointer types as template parameters won't catch vector attributes. The template will be instantiated a parameter matching the non-SIMD-enabled pointer type. All variables, class members, and function arguments bound to the template argument type will be regular function pointers. The use of such templates with a SIMD-enabled function pointer as a template function parameter, template class method parameter, or RHS of template class member assignment will lead to a dynamic cast to the non-SIMD-enabled function pointer and loss of vectorness.
- There is no way to overload or achieve template specialization by the vector attributes of a functional pointer
- There is no way to write functional traits to capture vector attributes for the sake of template metaprogramming.

```
// pointer typedefs and pointer declarations
typedef int
(*fptr_t)(int*, int);

#pragma omp declare simd
typedef int (*fptr_t1)(int*, int);

#pragma omp declare simd
#pragma omp declare simd linear(x)
typedef int (*fptr_t2)(int* a, int b);

fptr_t ptr
fptr_t1 ptr1
fptr_t2 ptr2

// function prototype that only differs in SIMD-enabled function decoration
// All these will have identical mangled names.
void foo(fptr_t);
```

```
void foo(fptr_t1);
void foo(fptr_t2);

// template instantiation
template <typename T>
void bar(T);
…
  bar(fptr);          // bar<fptr_t>
  bar(fptr1);         // bar<fptr_t>
  bar(fptr2);         // bar<fptr_t>
```

Indirect Invocation of a SIMD-enabled Function with Parallel Context

Typically, the invocation of a SIMD-enabled function directly or indirectly provides arrays wherever scalar arguments are specified as formal parameters.

The following invocations will give instruction-level parallelism by having the compiler issue special vector instructions.

```
#pragma omp declare simd
float (**vf_ptr)(float, float);

//operates on the whole extent of the arrays a, b, c
a[:] = vf_ptr[:] (b[:],c[:]);

// use the full array notation construct to also specify n
// as an extend and s as a stride
a[0:n:s] = vf_ptr[0:n:s] (b[0:n:s],c[0:n:s]);
```

NOTE The array notation syntax, as well as calling the SIMD-enabled function from the regular `for` loop, results in invoking the short vector variant in each iteration and utilizing the vector parallelism but the invocation is done in a serial loop, without utilizing multiple cores.

Vectorize a Loop Using the _Simd Keyword

In this section we introduce the `_Simd` keyword, which provides an alternative to the `simd` pragma. Just like the `simd` pragma, the `_Simd` keyword modifies a serial `for` loop for vectorization. The syntax is as follows:

```
_Simd [_Safelen(constant-expression)][_Reduction (reduction-identifier : list)]
```

The `_Simd` keyword and any clauses should come after the `for` keyword as in this example:

```
for _Simd (int i=0; i<10; i++){
  // loop body
}
```

Differences between the `simd` pragma and `_Simd` keyword:

- Omission of the `private` and `lastprivate` clauses of the `simd` pragma construct because C and C++ already have variable-scoping rules that allow a programmer to cleanly declare a private variable within the scope of a loop iteration

- The `linear` clause is omitted because the ability to increment multiple variables makes it unnecessary. See the following example:

```
float add_floats(float *a, float *b, int n){
  int i=0;
  int j=0;
  float sum=0;

  for _Simd _Reduction(+:sum) (i=0; i<n; i++, j+=2){
    a[i] = a[i] + b[j];
    sum += a[i];
  }
  return sum;
}
```

To ensure that your loop is vectorized keep the following in mind:

- The countable loop for the _Simd keyword has to conform to the for-loop style of an OpenMP* canonical loop form except that multiple variables may be incremented in the incr-expr (See the OpenMP* specification at www.openmp.org).
- The loop control variable must be a signed integer type.
- The vector values should be signed 8-, 16-, 32-, or 64-bit integers, single or double-precision floating point numbers, or single or double-precision complex numbers.
- You cannot use any control constructs to jump into or out of a SIMD loop. That includes the `break`, `return`, `goto`, and `throw` constructs.
- A SIMD loop may contain another loop (`for`, `while`, `do-while`) in it, but `goto` out of such inner loops is not supported. You may use `break` and `continue` with the inner loop.
- A SIMD loop performs memory references unconditionally. Therefore, all address computations must result in valid memory addresses, even though such locations may not be accessed if the loop is executed sequentially

simd Enforces vectorization of loops.

Function Annotations and the SIMD Directive for Vectorization

This topic presents specific C++ language features that better help to vectorize code.

> **NOTE**
> The SIMD vectorization feature is available for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x`.

The `__declspec(align(`*n*`))` declaration enables you to overcome hardware alignment constraints. The auto-vectorization hints address the stylistic issues due to lexical scope, data dependency, and ambiguity resolution. The SIMD feature's pragma allows you to enforce vectorization of loops.

You can use the `__declspec(vector)` `__attribute__(vector)` and the `__declspec(vector[clauses])` `__attribute__(vector(`*clauses*`))` declarations to vectorize user-defined functions and loops. For SIMD usage, the `vector` function is called from a loop that is being vectorized.

The C/C++ extensions for Array Notations `map` operations can be defined to provide general data parallel semantics, where you do not express the implementation strategy. You can write the same operation regardless of the size of the problem. The implementation uses the construct by combining SIMD, loops and tasking to implement the operation. With these semantics, you can choose more elaborate programming and express a single dimensional operation at two levels. You can use both task constructs and array operations to force a preferred parallel and vector execution.

The usage model of the `vector` declaration takes a small section of code generated for the function (*vectorlength*) of the array and exploits SIMD parallelism. The implementation of task parallelism is done at the call site.

The following table summarizes the language features that help vectorize code.

Language Feature	Description
`__declspec(align(`*n*`))`	Directs the compiler to align the variable to an *n*-byte boundary. Address of the variable is *address* `mod n=0`.
`__declspec(align(`*n*`,off))`	Directs the compiler to align the variable to an *n*-byte boundary with offset off within each *n*-byte boundary. Address of the variable is *address* `mod n=off`.
`__declspec(vector)` (Windows*) `__attribute__(vector)` (Linux* and macOS)	Combines with the `map` operation at the call site to provide the data parallel semantics. When multiple instances of the vector declaration are invoked in a parallel context, the execution order among them is not sequenced.
`__declspec(vector[`*clauses*`])` (Windows*) `__attribute__(vector(`*clauses*`))` (Linux* and macOS)	Combines with the `map` operation at the call site to provide the data parallel semantics with the following values for *clauses*: • processor clause: *processor(cpuid)* • vector length clause: *vectorlength(n)* • linear clause: *linear(param1:step1 [, param2:step2]…)* • uniform clause: *uniform(param [, param,]…)* • mask clause: *[no]mask* When multiple instances of the vector declaration are invoked in a parallel context, the execution order among them is not sequenced.
`restrict`	Permits the disambiguator flexibility in alias assumptions, which enables more vectorization.
`__declspec(vector_variant(`*clauses*`))` (Windows*) `__attribute__(vector_variant(`*clauses*`))` (Linux* and macOS)	Provides the ability to vectorize user-defined functions and loops. The *clauses* are as follows: • implements clause (required): *implements (function declarator) [, simd-clauses])* • simd-clauses (optional): one or more of the clauses allowed for the vector attribute
`__assume_aligned(`*a*`,`*n*`)`	Instructs the compiler to assume that array *a* is aligned on an *n*-byte boundary; used in cases where the compiler has failed to obtain alignment information.
`__assume(`*cond*`)`	Instructs the compiler to assume that the represented condition is true where the keyword appears. Typically used for conveying

Language Feature	Description
	properties that the compiler can take advantage of for generating more efficient code, such as alignment information.
Auto-vectorization Hints	
`#pragma ivdep`	Instructs the compiler to ignore assumed vector dependencies.
`#pragma vector {aligned|unaligned|always|temporal|nontemporal}`	Specifies how to vectorize the loop and indicates that efficiency heuristics should be ignored. Using the `assert` keyword with the `vector {always}` pragma generates an error-level assertion message if the compiler efficiency heuristics indicate that the loop cannot be vectorized. Use `#pragma ivdep!` to ignore the assumed dependencies.
`#pragma novector`	Specifies that the loop should never be vectorized.

NOTE
Some pragmas are available for both Intel® microprocessors and non-Intel microprocessors, but may perform additional optimizations for Intel® microprocessors than for non-Intel microprocessors.

User-Mandated Pragma	
`#pragma simd`	Enforces vectorization of loops.
omp simd	Transforms the loop into a loop that will be executed concurrently using SIMD instructions.

Guided Auto Parallelism

NOTE This feature has been deprecated.

The Guided Auto Parallelism (GAP) feature of the Intel®C++ Compiler is a tool that offers selective advice to improve the performance of serially-coded applications by suggesting changes that take advantage of the compiler's ability to automatically vectorize and parallelize code and improve the efficiency of data operations. Despite having the words “auto parallelism” in the name, this tool does not require a threaded code implementation to improve the execution performance of the code, or require that the code is already threaded or parallel.

Advanced optimization techniques, such as inter-procedural analysis or profile-guided feedback, are not needed to use this feature. Using the `[Q]guide` set of options in addition to the compiler options normally used is sufficient to enable the GAP feature, with the requirement that you must compile with `O2` or higher optimization levels. The compiler does not generate any object files or executables during the GAP run.

In debug mode (`/Zi` on Windows*, `-g` on Linux*), the compiler's optimization level defaults to `/Od` (on Windows*) or `-O0` (on Linux* and macOS); thus `O2` (or a higher level optimization) must be specified explicitly on the command-line.

NOTE Use the `[Q]diag-disable` option along with the `[Q]guide` option to direct the compiler to suppress specific diagnostic messages.
For example, the options: `//` **`(Windows*)`**`/Qguide, /Qdiag-disable:30534` and `//` **`(Linux* and macOS)`** `-guide, -diag-disable:30534` tell the compiler not to emit the 30534 diagnostic. The `[Q]diag-disable` mechanism works the same way as it does for compiler-warnings.

If you decide to follow the advice offered by the GAP tool by making the suggested code changes and/or using the suggested compiler options, you must then recompile the program without the `[Q]guide` option.

Any advice generated by the compiler when using the GAP tool is optional; it can be implemented or rejected. The advice typically falls under three broad categories:

- **Advice for source modifications:** The compiler advises you to make source changes that are localized to a loop-nest or a routine. For example, the tool may recommend that you use a local-variable for the upper-bound of a loop, (instead of a class member) or that you should initialize a local variable unconditionally at the top of the loop-body, or you may be told to add the `restrict` keyword to pointer-arguments of a function definition (if appropriate).
- **Advice to apply pragmas:** The compiler advises you to apply a new pragma on a certain loop-level if the pragma semantics can be satisfied (you must verify this). In many cases, you may be able to apply the pragma (thus implicitly asserting new program/loop properties) that the compiler can take advantage of to perform enhanced optimizations.
- **Advice to add compiler options:** The compiler advises you to add command-line options that assert new properties; for example, you may be asked to use the `[Q]ansi-alias` option or `/Qalias-args` (Windows*) or `-fargument-alias` (on Linux*) compiler options.

NOTE These suggested compiler options apply to the entire file. It is your responsibility to check that the properties asserted by these options are valid for the entire file, and not just the loop in question.

If you use GAP options along with option `[Q]parallel`, the compiler may suggest options to further parallelize your application. The compiler may also offer advice on enabling other optimizations of your application, including vectorization.

If you use the GAP options without enabling auto parallelism (without using the `[Q]parallel` option), the compiler may only suggest enabling optimizations such as vectorization for your application. This approach is recommended when you wish to improve the performance of a single-threaded code without the use of parallelization or when you want to improve the performance of threaded applications that do not rely on the compiler for auto parallelism.

Using Guided Auto Parallelism

The Guided Auto Parallelism feature of the Intel® C++ Compiler is a tool offering selective advice to improve the performance of serially-coded applications. The tool suggests changes that take advantage of the compiler's ability to automatically vectorize and parallelize code as well as improve the efficiency of data operations. The tool does not require that you implement threaded code to improve the execution performance of your code, nor does it require that your code is already threaded or parallel code.

To invoke this tool, use the compiler option `[Q]guide`*[=n]*. Using this option causes the compiler to generate messages suggesting ways to optimize the performance of your application. You can also use more specific compiler options such as `[Q]guide-vec`, `[Q]guide-par`, and `[Q]guide-data-trans` , to perform individual guided optimizations for vectorizing, parallelizing, and data transformation of your application.

When any guided auto parallelism option is used, the compiler provides only diagnostic advice. Object files or executables are not created in this mode. See the table below for descriptions of the options.

Syntax	Description
`[Q]guide`	Allows you to set a level of guidance for auto-vectorization and data transformation analysis. To obtain guidance for auto parallelism, you must use the `[Q]parallel` option along with the `[Q]guide` option.
`[Q]guide-par`	Allows you to set a level of guidance only for auto parallelism analysis. **NOTE** You must use the `[Q]parallel` option along with the `[Q]guide-par` option to get this advice.
`[Q]guide-vec`	Allows you to set a level of guidance for auto-vectorization analysis only.
`[Q]guide-data-trans`	Allows you to set a level of guidance for data transformation analysis only.

For all of the above options, the optional argument *n* specifies the level of guidance. The argument *n* takes the values `1-4`. When *n* is not specified, the default is `4`. If you specify *n*=`1` or `2`, a standard level of guidance is provided.

When you use *n*=`3` or *n*=`4`, you may get advanced messages. For example, you may get messages about how to optimize a particular loop-nest or get a message on how exception-handling inside a loop-nest affects optimizations for that loop-nest. Or you may get a message on how to provide extra information to the compiler on cost-modeling (expected values of trip-counts, and so on).

If you simultaneously specify a level of guidance for the general `[Q]guide` option and also for one or more of the other specific guide options, the level of guidance (*n*) for the specific guide option overrides the general `[Q]guide` option setting.

If you do not specify a level of guidance for the general `[Q]guide` option, but do set a level of guidance for one or more of the specific guide options, the `[Q]guide` option is set equal to the greatest value passed to the specific guide options.

Capturing Guidance Messages

The guided auto parallelism tool analyzes all of your serial code or individual parts of your code and generates advisory messages. By default, messages that are generated by the guided auto parallelism tool are output to `stderr`.

To capture messages in a file, use the options listed in the following table.

NOTE
The options listed in the following table must be used with the `[Q]guide`, `[Q]guide-par`, `[Q]guide-vec`, or `[Q]guide-data-trans` options. If not, they are ignored.

Syntax	Description
`[Q]guide-file`	Gathers all messages generated during a guided auto-parallelization run into the specified file.
`[Q]guide-file-append`	Allows you to specify the file into which all messages generated during a guided auto parallelism run should be appended.

For the above options, the *file_name* argument can also include a path. If a path is not specified, the file is created in the current working directory. If there is already a file named *file_name*, it is overwritten when you use the `[Q]guide-file` option. If you do not include an extension as part of the *file_name*, the extension `.guide` is appended.

Configuring Code Regions for GAP Messages

To limit guided auto parallelism analysis to specific regions (hotspots) in your application, use the option mentioned in the table below.

Syntax	Description
`[Q]guide-opts`	Allows you to analyze specified code elements, identified by *string*.

You must use the `[Q]guide-opts` option along with one of the guided auto parallelism options, such as `[Q]guide`, `[Q]guide-vec`, `[Q]guide-par`, and `[Q]guide-data-trans` . Use the *string* parameter to provide information about known areas of interest (hotspots). The *string* parameter takes one or more of the following variables: *filename*, *routine*, *range*. The compiler parses the *string* parameter and generates syntax errors if there are any.

Windows* Syntax

`/Qguide-opts:`*`string`*

Linux* and macOS Syntax

`-guide-opts=`*`string`*

Follow these guidelines when using the *string* parameter:

- Use only valid file names, routine names, and line numbers. The guided auto parallelism tool ignores invalid values and issues a diagnostic message stating what was ignored.
- Enclose routine names within single quotation marks. Specify original source names (demangled names) as routine names. A routine name alone may not always be sufficient to uniquely identify a routine. You may need to specify additional parameter information to uniquely identify the routine. For example:

Linux* and macOS:

```
-guide-
opts="foo.cpp,'CLHEP::StaticRandomSta::restore(std::basic_istream<char,std::char_traits<char>>&)'
"
-guide-opts="bar.f90,'module_1::routine_name`"
-guide-opts="baz.c,'c_routine_name'"
```

Windows*:

```
/Qguide-
opts:"foo.cpp,'CLHEP::StaticRandomSta::restore(std::basic_istream<char,std::char_traits<char>>&)'
"
/Qguide-opts:"bar.f90,'module_1::routine_name`"
/Qguide-opts:"baz.c,'c_routine_name'"
```

For any specified routine name, the GAP tool first tries to uniquely identify the routine using specified routine information. If that is not possible, then it selects all routines with the specified routine name. The GAP tool uses the parameter information, if specified, to narrow the selection.

- When inlining is involved, use the callee line numbers. The generated messages also use the callee line numbers.

Guided Auto Parallelism Messages

The Guided Auto Parallelism (GAP) messages provide advice that should improve optimizations.

The messages provide suggestions for:

- Automatic parallelization of loop nests
- Automatic vectorization of inner loops
- Data transformation

You must decide whether to follow a particular suggestion. For example, if the advice is to apply a particular pragma, you must understand the semantics of the pragma and carefully consider whether it can be safely applied to the loop (or loop nest) in question.

If you apply the pragma improperly, the compiler may generate incorrect code, causing the application to execute incorrectly.

If you do not fully understand the suggested advice, please refer to the relevant topics in the compiler documentation before applying that advice.

Once you apply the suggested advice, the compiler assumes that it is correct and it does not perform any checks or issue any warnings.

In general, messages that relate to loops tend to target vectorization and/or parallelization of loops. If you are not familiar with loop optimizations, please refer to the compiler documentation on this kind of optimization.

Loop Constructs

GAP Message (Diagnostic ID 30506)

Message

If the following operations(s) can be safely performed unconditionally, the loop at line %d will be vectorized by adding a "%s ivdep" statement right before the loop: %s.

Advice

Add "#pragma ivdep" before the specified loop.

This pragma enables the vectorization of the loop at the specified line. Insure that any conditional divide, sqrt, and inverse sqrt operations will not alter the exception semantics expected by the program when they are performed unconditionally.

Example

Consider the following:

```
void foo(float *a, int n) {
  int i;
  for (i=0; i<n; i++) {
    if (a[i] > 0) {
      a[i] = 1 / a[i];
    }
  }
  return;
}
```

In this case, the compiler is unable to vectorize the loop if compiled with floating-point exception semantics (such as `/fp:except option`) because the condition "a[i] > 0" may be guarding floating-point exceptions for the divide.

If you determine it is safe to do so, you can add the pragma as follows:

```
void foo(float *a, int n) {
  int i;
#pragma ivdep
  for (i=0; i<n; i++) {
    if (a[i] > 0) {
      a[i] = 1 / a[i];
    }
  }
  return;
}
```

Verify

Confirm that the program operands have safe values for all iterations.

GAP Message (Diagnostic ID 30513)

Message

Insert a "%s ivdep" statement right before the loop at line %d to vectorize the loop.

Advice

Add "#pragma ivdep" before the specified loop. This pragma enables the vectorization of the loop at the specified line by ignoring some of the assumed cross-iteration data dependencies.

Example

Consider the following:

```
void foo(float *a, int x, int n) {
  int i;
  for (i=0; i<n; i++) {
    a[i] = a[i+x]+1;
  }
  return;
}
```

In this case, the compiler is unable to vectorize the loop because x could be -1, where each iteration is dependent on the previous iteration. If x is known to be positive, you can vectorize this loop.

If you determine it is safe to do so, you can add the pragma as follows:

```
void foo(float *a, int x, int n) {
  int i;
#pragma ivdep
  for (i=0; i<n; i++) {
    a[i] = a[i+x]+1;
  }
  return;
}
```

Verify

Confirm that any arrays in the loop do not have unsafe cross-iteration dependencies. A cross-iteration dependency exists if a memory location is modified in an iteration of the loop and accessed by a read or a write statement in another iteration of the loop. Make sure that there are no such dependencies, or that any cross-iteration dependencies can be safely ignored.

GAP Message (Diagnostic ID 30515)

Message

Assign a value to the variable(s) "%s" at the beginning of the body of the loop in line %d. This will allow the loop to be vectorized.

Advice

You should unconditionally initialize the scalar variables at the beginning of the specified loop. This allows the vectorizer to privatize those variables for each iteration and vectorize the loop. You must ensure that all the uses of those variables see the same values before and after the source code change.

Example

Consider the following:

```
void foo(float *a, int n) {
  int i;
  float b;
  for (i=0; i<n; i++) {
    if (a[i] > 0) {
      b = a[i];
      a[i] = 1 / a[i];
    }
    if (a[i] > 1) {
      a[i] += b;
    }
  }
  return;
}
```

In this case, the compiler is unable to vectorize the loop because it failed to privatize the variable *b*. Vectorization is assisted when assignment to *b* occurs in each iteration where the value of *b* is used. One of the ways to do this is to assign the value in every iteration.

If you determine it is safe to do so, you can modify the program code as follows:

```
void foo(float *a, int n) {
  int i;
  float b;
  for (i=0; i<n; i++) {
    b = a[i];
    if (a[i] > 0) {
      a[i] = 1 / a[i];
    }
    if (a[i] > 1) {
      a[i] += b;
    }
  }
  return;
}
```

Verify

Confirm that in the original program, any variables read in any iteration of the loop have been defined earlier in the same iteration.

GAP Message (Diagnostic ID 30519)

Message

Insert a "%s parallel" statement right before the loop at line %d to parallelize the loop.

Advice

Add "#pragma parallel" before the specified loop. This pragma enables the parallelization of the loop at the specified line by ignoring assumed cross-iteration data dependencies.

Example

Consider the following:

```
void foo(float *a, int m, int n) {
  int i;
  for (i=0; i<n; i++) {
    a[i] = a[i+m]+1;
  }
  return;
}
```

In this case, the compiler is unable to parallelize the loop without further information about *m*. For example, if *m* is negative, then each iteration will be dependent on the previous iteration. However, if *m* is known to be greater than *n*, you can parallelize the loop.

If you determine it is safe to do so, you can add the pragma as follows:

```
void foo(float *a, int m, int n) {
  int i;
#pragma parallel
  for (i=0; i<n; i++) {
    a[i] = a[i+m]+1;
  }
  return;
}
```

Verify

Confirm that any arrays in the loop do not have cross-iteration dependencies. A cross-iteration dependency exists if a memory location is modified in an iteration of the loop and accessed by a read or a write statement in another iteration of the loop.

GAP Message (Diagnostic ID 30521)

Message

Assign a value to the variable(s) "%s" at the beginning of the body of the loop in line %d. This will allow the loop to be parallelized.

Advice

Check to see if you can unconditionally initialize the scalar variables at the beginning of the specified loop. If so, do the code change for such initialization (standard), or list the variables in the private clause of a parallel pragma (advanced). This allows the parallelizer to privatize those variables for each iteration and to parallelize the loop.

Example

Consider the following:

```
#define N 100000
double A[N], B[N];

void foo(int cond1, int cond2){
  int i, t=7;
  for (i=0; i<N; i++){
    if (cond1) {
      t = i+1;
    }
```

```
    if (cond2) {
      t = i-1;
    }
    A[i] = t;
  }
}
```

In this case, the compiler does not parallelize the loop because it cannot privatize the variable *t* without further information. If you know that cond1 or cond2 is true, or both cond1 and cond2 are true, then you can assist the parallelizer by ensuring that any iteration that uses *t* also writes to *t* before its use in the same iteration. One of the ways to do this is to assign a value to *t* at the top of each iteration.

If you determine it is safe to do so, you can modify the program code as follows:

```
#define N 100000
double A[N], B[N];

void foo(int cond1, int cond2){
  int i, t=7;
  for (i=0; i<N; i++){
    t=0;
    if (cond1) {
      t = i+1;
    }
    if (cond2) {
      t = i-1;
    }
    A[i] = t;
  }
}
```

Verify

Confirm that in the original program, any variables read in any iteration of the loop have been defined earlier in the same iteration.

See Also

GAP Message (Diagnostic ID 30523)

GAP Message (Diagnostic ID 30522)

Message

Insert a "%s parallel private(%s)" statement right before the loop at line %d to parallelize the loop.

Advice

Add "#pragma parallel private" before the specified loop. This pragma enables the parallelization of the loop at the specified line.

Example

Consider the following:

```
float A[10][10000];
float B[10][10000];
float C[10][10000];
void foo(
 int n,
 int m1,
```

```
 int m2
)
{
  int i,j;
  float W[10000];
  for (i =0; i < n; i++) {
    for (j =0; j < m1; j++)
      W[j]  =  A[i][j] * B[i][j];
    for (j =0; j < m2; j++)
      C[i][j] += W[j] + 1.0;
  }
}
```

In this case, the compiler does not parallelize the loop since it cannot determine whether m1 >= m2.

If you know that this property is true, and that no element of W is fetched before it is written to after the loop, then you can use the recommended pragma.

If you determine it is safe to do so, you can add the pragma as follows:

```
float A[10][10000];
float B[10][10000];
float C[10][10000];
void foo(
 int n,
 int m1,
 int m2
)
{
  int i,j;
  float W[10000];
#pragma parallel private (W)
  for (i =0; i < n; i++) {
    for (j =0; j < m1; j++)
      W[j]  =  A[i][j] * B[i][j];
    for (j =0; j < m2; j++)
      C[i][j] += W[j] + 1.0;
  }
}
```

Verify

Before an element of an array can be read in the loop, there must have been a previous write to it during the same loop iteration. In addition, if an element is read after the loop, there must have been a previous write to it before the read after the loop.

GAP Message (Diagnostic ID 30523)

Message

Assign a value to the variable(s) "%s" at the beginning of the body of the loop in line %d. This will allow the loop to be parallelized.

Advice

Check to see if you can unconditionally initialize the scalar variables at the beginning of the specified loop. If so, do the code change for such initialization (standard), or list the variables in the private clause of a parallel pragma (advanced). This allows the parallelizer to privatize those variables for each iteration and to parallelize the loop.

Example

Consider the following:

```
#define N 100000
double A[N], B[N];
```

```
void foo(int cond1, int cond2){
  int i, t=7;
  for (i=0; i<N; i++){
    if (cond1) {
      t = i;
    }
    if (cond2) {
      A[i] = t;
    }
  }
}
```

In this case, the compiler does not parallelize the loop because it cannot privatize the variable *t* without further information. If you know that cond2 always implies cond1, then you can assist the parallelizer by ensuring that any iteration that uses *t*, also writes to *t* before it is used in the same iteration. One of the ways to do this is to assign a value to *t* at the top of every iteration. Another way is to list the variables to be privatized in the private clause of a parallel pragma.

If you determine it is safe to do so, you can add the pragma as follows:

```
#define N 100000
double A[N], B[N];

void foo(int cond1, int cond2){
  int i, t=7;
#pragma private (t)
  for (i=0; i<N; i++){
    if (cond1) {
      t = i;
    }
    if (cond2) {
      A[i] = t;
    }
  }
}
```

Verify

Confirm that in the original program, any variables read in any iteration of the loop have been defined earlier in the same iteration or have been privatized by means of the private clause of a parallel pragma.

GAP Message (Diagnostic ID 30521)

GAP Message (Diagnostic ID 30525)

Message

Insert a "%s loop count min(%d)" statement right before the loop at line %d to parallelize the loop.

Advice

Add "#pragma loop count" before the specified loop. This pragma indicates the minimum trip count (number of iterations) of the loop that enables the parallelization of the loop.

The minimum trip count required to parallelize the loop may differ depending on the target architecture, and this will be reflected in the message generated.

Example

Consider the following:

```
#define N 10000
float A[N], B[N];

void foo(int n) {
  int i;
  for (i =0; i < n; i++) {
      A[i] = A[i] + B[i] * B[i] + 1.5;
  }
}
```

In this case, the compiler may not parallelize the loop because it is not sure that n is large enough for the parallelization to be beneficial.

If you determine it is safe to do so, you can add the pragma as follows:

```
#define N 10000
float A[N], B[N];

void foo(int n) {
  int i;
#pragma loop count min(128)
  for (i =0; i < n; i++) {
      A[i] = A[i] + B[i] * B[i] + 1.5;
  }
}
```

Verify

Confirm that the loop has the minimum number of iterations, as specified in the diagnostic message.

See Also

Guided Auto Parallelism Messages provides advice for improving optimizations

GAP Message (Diagnostic ID 30526)

Message

To parallelize the loop at line %d, annotate the routine %s with %s.

Advice

If the loop contains a call to a function, the compiler cannot parallelize the loop without more information about the function being called.

However, if the function being called in the loop is a const function or a concurrency-safe function, then the call does not inhibit parallelization of the loop.

Example

Consider the following:

```
#define N 10000
double A[N], B[N];
int bar(int);
void foo(){
  int i;
  for (i=0;i<N;i++){
    A[i] = B[i] * bar(i);
  }
}
```

In this case, the compiler does not parallelize the loop because it is not safe to do so without further information about routine `bar`, which is being called.

If you determine it is safe to do so, you can modify the program code as follows:

```
#define N 10000
double A[N], B[N];
__declspec(const) int bar(int);
void foo(){
  int i;
  for (i=0;i<N;i++){
    A[i] = B[i] * bar(i);
  }
}
```

If you determine it is safe to do so, an alternative way you can modify the program code is as follows:

```
#define N 10000
double A[N], B[N];
__declspec(concurrency_safe(profitable)) int bar(int);
void foo(){
  int i;
  for (i=0;i<N;i++){
    A[i] = B[i] * bar(i);
  }
}
```

Verify

Confirm the routine satisfies the semantics of this annotation. A weaker annotation able to achieve a similar effect is `__declspec(concurrency_safe(profitable)`.

See Also

GAP Message (Diagnostic ID 30528)

`__declspec(concurrency_safe)` declaration

`__declspec(const)` declaration

GAP Message (Diagnostic ID 30528)

Message

Add "%s" to the declaration of routine "%s" in order to parallelize the loop at line %d. Adding "%s" achieves a similar effect.

Advice

Confirm that the routine specified is indeed a const function or a concurrency-safe function before following the advice to add the annotation.

If the routine is not one of these kinds of functions, try to inline it with #pragma forceinline recursive. This action may or may not be beneficial.

Example

Consider the following:

```
#define N 10000
double A[N], B[N];
int bar(int);
void foo(){
  int i;
  for (i=0;i<N;i++){
    A[i] = B[i] * bar(i);
  }
}
```

In this case, the compiler does not parallelize the loop because it is not safe to do so without further information about routine `bar`, which is being called.

If you determine it is safe to do so, you can add the pragma as follows:

```
#define N 10000
double A[N], B[N];
void foo(){
  int i;
#pragma forceinline recursive
  for (i=0;i<N;i++){
    A[i] = B[i] * bar(i);
  }
}
```

Verify

Confirm that the routine satisfies the semantics of this declaration. Another way to help the loop being parallelized is to inline the routine with the forceinline recursive pragma, but this method does not guarantee parallelization.

GAP Message (Diagnostic ID 30526)

GAP Message (Diagnostic ID 30531)

Message

Store the value of the upper-bound expression of the loop at line %d into a temporary local variable, and use this variable as the new upper-bound expression of the loop. To do this, insert a statement of the form "temp = upper-bound of loop" right before the loop, where "temp" is the newly created local variable. Choose a variable name that is unique, then replace the loop's original upper-bound expression with "temp".

Advice

Use a local-variable for the loop upper-bound if the upper-bound does not change during the execution of the loop. This enables the compiler to recognize the loop as a proper counted do loop, which enables various loop optimizations including vectorization and parallelization.

This message appears when the compiler cannot output the exact upper-bound variable to be replaced.

Example

Consider the following:

```
class FooClass  {
public:
    const int getValue() { return m_numTimeSteps;}
        void Foo2(double*  vec);
private:
        int m_numTimeSteps;
};
void FooClass::Foo2(double*  vec)
{
        // this will not vectorize
        for (int k=0; k < m_numTimeSteps; k++)
                vec[k] = 0.0;

        // this will not vectorize
        for (int k=0; k < getValue(); k++)
                vec[k] = 0.0;

        // this will vectorize
        int ub1 = m_numTimeSteps;
        for (int k=0; k < ub1; k++)
                vec[k] = 0.0;

        // this will vectorize
        int ub2 = getValue();
        for (int k=0; k < ub2; k++)
                vec[k] = 0.0;
}
```

Verify

Confirm that the value of the upper-bound expression does not change throughout the entire execution of the loop.

See Also

GAP Message (Diagnostic ID 30532)

GAP Message (Diagnostic ID 30532)

Message

Store the value of the upper-bound expression (%s) of the loop at line %d into a temporary local variable, and use this variable as the new upper-bound expression of the loop. To do this, insert a statement of the form "temp = %s" right before the loop, where "temp" is the newly created local variable. Choose a variable name that is unique, then replace the loop's original upper-bound expression with "temp".

Advice

Use a local-variable for the loop upper-bound if the upper-bound does not change during the execution of the loop. This enables the compiler to recognize the loop as a proper counted do loop, which in turn enables various loop optimizations including vectorization and parallelization.

This message appears when the compiler can output the exact upper-bound variable to be replaced.

Example

Consider the following:

```
typedef struct  {
    float*      data;
} Vector;

typedef struct {
    int         len;
} NetEnv;
```

```
// This one does not vectorize
void
mul(
    NetEnv*     ne,
    Vector*     rslt,
    Vector*     den,
    Vector*     num)
{
    float*      r;
    float*      d;
    float*      n;
    int i;

    r = rslt->data;
    d = den->data;
    n = num->data;

    for (i = 0; i < ne->len; ++i) {
        r[i] = n[i] * d[i];
    }
    return;
}
```

In this case, the compiler is unable to vectorize the loop at setting `O2`, the default.

If you determine it is safe to do so, you can modify the program code as follows:

```
typedef struct {
    float*      data;
} Vector;

typedef struct {
    int         len;
} NetEnv;

// This one vectorizes
void
mul(
    NetEnv*     ne,
    Vector*     rslt,
    Vector*     den,
    Vector*     num)
{
    float*      r;
    float*      d;
    float*      n;
    int i, local_len;
```

```
    r = rslt->data;
    d = den->data;
    n = num->data;

    local_len = ne->len;
    for (i = 0; i < local_len; ++i) {
        r[i] = n[i] * d[i];
    }
    return;
}
```

Verify

Confirm that the value of the upper-bound expression does not change throughout the entire execution of the loop.

GAP Message (Diagnostic ID 30531)

GAP Message (Diagnostic ID 30533)

Message

Compile with the %s option to vectorize and/or parallelize the loop at line %d.

Advice

Use the `[q or Q]opt-subscript-in-range` option for the specified file during compilation.

This option helps the compiler vectorize and parallelize the loop at the specified line. You must verify that the loops in the file do not contain very large integers and are not likely to generate very large integers in intermediate computations. A very large integer is loosely defined as follows: On an *n*-bit machine, a very large integer is typically >= 2^{n-2}. For example, on a 32-bit machine, a very large integer would be >= 2^{30}.

Example

Consider the following:

```
int f(int* A, int upper1, int upper2){
  long extra = 100.0;
  int return_val = 0;
  int val;
  for(int j=0; j < upper1; j++){
    for(int i = 0; i < upper2; i++){
      val = A[i*extra];
      return_val += val;
    }
  }
  return return_val;
}
```

If you determine it is safe to do so, compiling this example with the `[q or Q]opt-subscript-in-range` option results in vectorization of the innermost loop.

Verify

Confirm that no loop in the program contains or generates very large integers (typically very large integers are >= 2^{30}).

GAP Message (Diagnostic ID 30534)

Message

Add %s option for better type-based disambiguation analysis by the compiler if appropriate (the option will apply for the entire compilation). This will improve optimizations for the loop at line %d.

Advice

Use option `[Q]ansi-alias` for the specified file. This option will help the compiler to optimize the loop at the specified line. You must verify that the ANSI rules are followed for the entire file. gcc assumes this property by default in default setting `O2`; the Intel compiler does not. This option is particularly useful for C++ programs since it enables type-based disambiguation between pointers and other elemental datatypes (that in turn enables optimizations such as vectorization and parallelization).

Option `[Q]ansi-alias` enables or disables use of ANSI aliasing rules optimizations, and assert that the program adheres to these rules.

ANSI-aliasing rules are described in the Standards documentation:

- C: ISO/IEC 9899, chapter 6.5 paragraph 7
- C++: ISO/IEC 14882, chapter 3.10, paragraph 15

Example

Consider the following:

```
#include <stddef.h>

template<typename T>
class blocked_range {
    T my_begin;
    T my_end;
public:
    blocked_range();
    T begin() const {return my_begin;}
    T end() const {return my_end;}
};

class ApplyMatAdd {
    double *const A, *const B, *const C;
    const size_t size;
public:
    ApplyMatAdd(double *A_, double *B_, double *C_, size_t size_) : A(A_), B(B_), C(C_),
size(size_) {}
    void operator()( const blocked_range<size_t>& range ) const;
};

void ApplyMatAdd::operator()( const blocked_range<size_t>& range ) const {
    for (size_t i=range.begin(); i<range.end(); ++i) {
        for (size_t j=0; j<size; ++j) {
            C[i*size + j] = A[i*size + j] + B[i*size + j];
        }
    }
}
```

In this case, the compiler is unable to vectorize the innermost loop at setting `O2`, the default.

If you determine it is safe to do so, you can compile the above example with the `[Q]ansi-alias` option, which enables vectorization of the innermost loop.

Verify

Make sure that the semantics of this option are obeyed for the entire compilation.

GAP Message (Diagnostic ID 30535)

Message

Removing Exception-Handling code associated with the loop-body may enable more optimizations for the loop at line %d.

Advice

Loop optimizations could not be performed because of exception-handling code inside the loop body. You can remove the exception-handling code or use different libraries, etc.

Example

Consider the following:

```
#include <boost/numeric/ublas/vector.hpp>
#include <boost/numeric/ublas/io.hpp>

namespace ublas = boost::numeric::ublas;

int main () {
  unsigned size = 1000;
  ublas::vector<double> dest(size), src(size), arg(src);

  for (int i = 0; i < size; ++ i) {
    src(i) = i * 1.2;
    arg(i) = i * 2.3;
  }

  // Loop to be vectorized
  dest = src + 1.5 * arg;

  return 0;
};
```

In this case, the compiler is unable to vectorize the loop at setting `O2`, the default. Remove the exception-handling code or recode using different libraries.

Verify

Make sure that the restructured code without exception-handling code inside the loop-body follows original program semantics.

GAP Message (Diagnostic ID 30536)

Message

Add %s option for better type-based disambiguation analysis by the compiler, if appropriate (the option will apply for the entire compilation). This will improve optimizations such as vectorization for the loop at line %d.

Advice

Use option `-fnoargument-alias` (Linux* OS and macOS) or `/Qno-alias-args` (Windows* OS) for the specified file. This option will help the compiler to optimize the loop at the specified line. The user has to verify that there is no argument-aliasing for routines in this file before applying this option for the current file. This option is particularly useful for C++ programs since it enables type-based disambiguation between pointers that are passed in as arguments, which in turn enables optimizations such as vectorization and parallelization.

Option `-fargument-alias` (Linux* OS and macOS) and `/Qalias-args` (Windows* OS) enable or disable the C/C++ rule that function arguments may be aliased. When disabling the rule, you assert that this is safe.

Example

Consider the following example that demonstrates a violation of `-fnoargument-alias` or `/Qno-alias-args`:

```
void f(double *p, double *q, double *r) {
  int i;
  for (i = 0; i < n; i++)
    p[i] = q[i] + r[i];
}

int n, m;
double A[100], B[100];
...
f(&A[n], &A[m], &B[0]);
```

Since both pointers *p* and *q* will be pointing to the same array *A*, there may be overlap depending on the values of *n* and *m*.

Also, you cannot use the restrict keyword for parameters *p* and *q* in the function f for this test case.

You must analyze all the callers of function *f* in the current file and make sure that such overlap does not exist before applying `-fnoargument-alias` or `/Qno-alias-args` or the restrict qualifier. Note that such call sites may occur in other files as well.

Verify

Make sure that the semantics of this option is obeyed for the entire compilation.

Another way to get the same effect is to add the "restrict" keyword to each pointer-typed formal parameter of the routine "%s". This allows optimizations such as vectorization to be applied to the loop at line %d. Make sure that semantics of the "restrict" pointer qualifier is satisfied; in the routine, all data accessed through the pointer must not be accessed through any other pointer.

See Also

GAP Message (Diagnostic ID 30537)

GAP Message (Diagnostic ID 30537)

Message

Add the "restrict" keyword to each pointer-typed formal parameter of the routine "%s". This allows optimizations such as parallelization and vectorization to be applied to the loop at line %d.

Advice

Rather than using option -fnoargument-alias (Linux* OS and macOS) or /Qno-alias-args (Windows* OS), which affects the entire file, you can add the restrict qualifier to the pointer arguments to this routine. This change is more localized since it affects only the routines where the keyword is applied.

The restrict qualifier is part of C standard C99. This qualifier can be applied to a data pointer to indicate that during the scope of that pointer declaration, all data accessed through it will be accessed only through that pointer but not through any other pointer. So, the restrict keyword enables the compiler to perform certain optimizations based on the premise that a given object cannot be changed through another pointer. You must ensure that restrict-qualified pointers are used as they are intended to be used. Otherwise, undefined behavior may result.

The Intel® Compiler requires that you also specify option `[Q]restrict` when compiling non-C99 programs.

Example

Consider the following:

```
void matrix_mul_matrix(int  N, float * C,  float  *A,  float  *B) {
  int  i,j,k;

  for (i=0; i<N; i++) {
    for (j=0; j<N; j++) {
      C[i*N+j]=0;
      for(k=0;k<N;k++) {
        C[i*N+j]+=A[i*N+k] * B[k*N+j];
      }
    }
  }
}
```

In this case, the compiler is unable to apply loop optimizations such as loop-interchange and vectorization at default setting `O2`.

If you determine it is safe to do so, you can modify the program code as follows:

```
void matrix_mul_matrix(int  N, float * restrict C,  float  * restrict A,  float
 * restrict B) {
  int  i,j,k;

  for (i=0; i<N; i++) {
    for (j=0; j<N; j++) {
      C[i*N+j]=0;
      for(k=0;k<N;k++) {
        C[i*N+j]+=A[i*N+k] * B[k*N+j];
      }
    }
  }
}
```

Note that instead of using the restrict qualifier, you could have specified `-fnoargument-alias` or `/Qno-alias-args` before compiling the code.

Verify

Make sure that semantics of the "restrict" pointer qualifier is satisfied: in the routine, all data accessed through the pointer must not be accessed through any other pointer.

See Also

GAP Message (Diagnostic ID 30536)

GAP Message (Diagnostic ID 30538)

Message

Moving the block of code that consists of a function-call (line %d), if-condition (line %d), and an early return (line %d) to outside the loop may enable parallelization of the loop at line %d.

Advice

Move the function call and an associated return from inside the loop (perhaps by inserting them before the loop) to help parallelize the loop.

This kind of function-leading-to-return inside a loop usually handles some error-condition inside the loop. If this error check can be done before starting the execution of the loop without changing the program semantics, the compiler may be able to parallelize the loop thus improving performance.

Example

Consider the following:

```
extern int num_nodes;
typedef struct TEST_STRUCT {
    // Coordinates of city1
    float latitude1;
    float longitude1;

    // Coordinates of city2
    float latitude2;
    float longitude2;
} test_struct;

extern int *mark_larger;
extern float *distances, **matrix;
extern test_struct** nodes;
extern test_struct ***files;
extern void init_node(test_struct *node, int i);
extern void process_nodes(void);
float compute_max_distance(void);

extern int check_error_condition(int width);

#include <math.h>
#include <stdio.h>

void process_nodes(int width)
{
  float const R = 3964.0;
  float temp, lat1, lat2, long1, long2, result, pat2;
  int m, j, temp1 = num_nodes;

      nodes = files[0];
      m = 1;

#pragma loop count min(4)
#pragma parallel
      for (int k=0; k < temp1; k++) {

            if (check_error_condition(width)) {
```

```
                return;
            }

         lat1 = nodes[k]->latitude1;
            lat2 = nodes[k]->latitude2;

            long1 = nodes[k]->longitude1;
            long2 = nodes[k]->longitude2;

            // Compute the distance between the two cities
            temp = sin(lat1) * sin(lat2) + cos(lat1) * cos(lat2) *
                                              cos(long1-long2);
            result = 2.0 * R * atan(sqrt((1.0-temp)/(1.0+temp)));

            pat2 = 0;
            for(j=0; j<width; j++) {
              pat2 += distances[j];
              matrix[k][j] = distances[k]+j;
            }
            // Store the distance computed in the distances array
            if (result > distances[k]) {
                distances[k] = result + pat2;
            }
      }
}
```

In this case, the compiler is unable to parallelize the loop at line 38.

If you determine it is safe to do so, you can modify the above code as follows:

```
extern int num_nodes;
typedef struct TEST_STRUCT {
    // Coordinates of city1
    float latitude1;
    float longitude1;

    // Coordinates of city2
    float latitude2;
    float longitude2;
} test_struct;

extern int *mark_larger;
extern float *distances, **matrix;
extern test_struct** nodes;
extern test_struct ***files;
extern void init_node(test_struct *node, int i);
extern void process_nodes(void);
float compute_max_distance(void);

extern int check_error_condition(int width);

#include <math.h>
#include <stdio.h>

void process_nodes(int width) {
  float const R = 3964.0;
  float temp, lat1, lat2, long1, long2, result, pat2;
  int m, j, temp1 = num_nodes;
```

```
      nodes = files[0];
      m = 1;

      if (check_error_condition(width)) {
      return;
      }

#pragma loop count min(4)
#pragma parallel
      for (int k=0; k < temp1; k++) {

         lat1 = nodes[k]->latitude1;
            lat2 = nodes[k]->latitude2;

            long1 = nodes[k]->longitude1;
            long2 = nodes[k]->longitude2;

            // Compute the distance between the two cities
            temp = sin(lat1) * sin(lat2) + cos(lat1) * cos(lat2) *
                                               cos(long1-long2);
            result = 2.0 * R * atan(sqrt((1.0-temp)/(1.0+temp)));

            pat2 = 0;
            for(j=0; j<width; j++) {
              pat2 += distances[j];
              matrix[k][j] = distances[k]+j;
            }
            // Store the distance computed in the distances array
            if (result > distances[k]) {
                distances[k] = result + pat2;
            }
      }
}
```

Verify

Confirm that the function call does not rely on any computation inside the loop and that restructuring the code as suggested above, retains the original program semantics.

GAP Message (Diagnostic ID 30753)

Message

Convert array of struct "%s" into a new struct whose fields are arrays of the corresponding fields in the original struct. This improves performance due to better data locality.

Advice

You should apply full peeling to a class or structure. This is done by splitting a class or structure into separate fields. This should improve performance by better utilizing the processor cache. This message is generated only when the entire application is built with Interprocedural Optimization (IPO). This transformation requires that you change all access to any peeled structure and its fields in the entire application. In some cases, it may not be easy to change source code to apply full peeling.

Example

Consider the following:

```
// peel.c
#include <stdio.h>
#include <stdlib.h>

#define N 100000
int a[N];
double b[N];
struct S3 {
    int *pi;
    double d;
    int j;
};

struct S3 *sp;

void init_hot_s3_i() {

    int ii = 0;

    for (ii = 0; ii < N; ii++) {
        sp[ii].pi = &a[ii];
    }
}
void init_hot_s3_d() {
    int ii = 0;

    for (ii = 0; ii < N; ii++) {
        sp[ii].d = b[ii];
    }
}
void init_hot_s3_j() {
    int ii = 0;

    for (ii = 0; ii < N; ii++) {
        sp[ii].j = 0;
    }
}
void dump_s3() {
    int ii;

    for (ii = 0; ii < N; ii++) {
        printf("i= %d ", *(sp[ii].pi));
        printf("d= %g \n", sp[ii].d);
        printf("j= %g \n", sp[ii].j);
    }
}

main() {

   sp = (struct S3 *)calloc(N, sizeof(struct S3));
   init_hot_s3_i();
   init_hot_s3_d();
   init_hot_s3_j();
   dump_s3();
}
```

In this case, the compiler tells you to convert struct "S3".

If you determine it is safe to do so, you can modify the program code as follows:

```
#include <stdio.h>
#include <stdlib.h>

#define N 100000
int a[N];
double b[N];
struct S3 {
    int *pi;
};
struct new_d {
    double d;
};
struct new_j {
    int j;
};

struct S3 *sp;
struct new_d *sp_d;
struct new_j *sp_j;

void init_hot_s3_i() {

    int ii = 0;

    for (ii = 0; ii < N; ii++) {
        sp[ii].pi = &a[ii];
    }
}
void init_hot_s3_d() {
    int ii = 0;

    for (ii = 0; ii < N; ii++) {
        sp[ii].d = b[ii];
    }
}
void init_hot_s3_j() {
    int ii = 0;

    for (ii = 0; ii < N; ii++) {
        sp[ii].j = 0;
    }
}
void dump_s3() {
    int ii;

    for (ii = 0; ii < N; ii++) {
        printf("i= %d ", *(sp[ii].pi));
        printf("d= %g \n", sp[ii].d);
        printf("j= %g \n", sp[ii].j);
    }
}

main() {

   sp = (struct S3 *)calloc(N, sizeof(struct S3));
```

```
   init_hot_s3_i();
   init_hot_s3_d();
   init_hot_s3_j();
   dump_s3();
}
```

Verify

Make sure that the restructured code satisfies the original program semantics.

GAP Message (Diagnostic ID 30754)

Message

Aligning the fields '%s' in the structure '%s' on an 8-byte boundary may improve performance. Default alignment of double precision floating point data is 4-byte on the Linux IA32 platform. [ALTERNATIVE] Reordering fields of the structure may help to align double precision floating point data on an 8-byte boundary. [ALTERNATIVE] Another way is to use __attribute__((aligned(8))) for the fields '%s' in the structure '%s' to allocate the fields on an 8-byte boundary.

This messsage is only available on Linux* systems.

Advice

You must reorder the fields of a class or structure type to make "double" fields 8-byte aligned. On Linux* systems on IA-32 architecture, "double" fields are not required to be 8-byte aligned. This should enable optimizations like vectorization to generate better code. You must verify that the application code does not rely on the structure fields to be laid out in a specific order.

Example

Consider the following:

```
//alignment.c
#include <stdlib.h>
#include <stdio.h>

#define N 1000

struct S {
    int i;
    double d1;
    double d2;
    double d3;
};

struct S *sp;

static struct S*
alloc_s(int num) {
    struct S * temp;

    temp = calloc(num, sizeof(struct S));
    return temp;
}

struct S temp;
```

```
static void
swap_s(int i, int j) {
    memcpy(&temp, sp + i, sizeof(struct S));
    memcpy(sp + i, sp + j, sizeof(struct S));
    memcpy(sp+ j, &temp, sizeof(struct S));
}

static void
init_s(int num) {
    int ii;

    for (ii = 0; ii < num; ii++) {
        sp[ii].i = ii;
        sp[ii].d1 = (double) ii + 1;
        sp[ii].d2 = (double) ii + 2;
        sp[ii].d3 = (double) ii + 3;
    }
}

main() {
    int ii;
    double d = 0.0;

    sp = alloc_s(N);

    for(ii = 0; ii < N -1; ii += 2) {
        swap_s(ii, ii+1);
    }

    for (ii = 0; ii < N ; ii++) {
        sp[ii].d1 = sp[ii].d1 * sp[ii].d2 * sp[ii].d3;
        d += sp[ii].d1;
    }

    for (ii = 0; ii < N ; ii++) {
        printf(" %d:  %g   %g  %g  \n", sp[ii].i, sp[ii].d1, sp[ii].d2, sp[ii].d3);
    }
}
```

In this case, when the program is compiled, the compiler generates a message saying that aligning the fields 'd1, d2, d3' in the structure 'S' on an 8-byte boundary may improve performance.

Alternatively, '__attribute__((aligned(8)))' can be used to align 'd1, d2, d3' on an 8-byte boundary. One possible way to do this is shown below:

```
struct S {
    int i;
    __attribute__((aligned(8)))  double d1;
    double d2;
    double d3;
};
```

Verify

Make sure that the restructured code satisfies the original program semantics. Note that size of the structure may change due to the alignment changes. Make sure that the change in the structure layout satisfies the original program semantics.

GAP Message (Diagnostic ID 30755)

Message

Reordering the fields of the structure '%s' will improve data locality. Suggested field order: '%s'.

Advice

You should reorder the fields of the class or structure type in the specified order. This should improve performance by better utilizing the processor cache.

You must verify that the application code does not rely on the structure fields to be laid out in a specific order. For example, if the application code uses the address of a field to access other fields, it may stop working once the field reordering is applied. Note also that such code is not considered valid.

Example

Consider the following:

```
//field_reord.c
struct str {
    int a1, b1, carr[100], c1, d1, e1;
};

extern struct str sp[];

int hot_func1() {
    int i, ret = 0;

    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret += sp[i].c1;
    }
    return ret;
}

int hot_func2() {
    int ret = 0, i;
    for (i = 0; i < 100000; i++) {
        ret += sp[i].a1;
        ret -= sp[i].e1;
    }
    return ret;
}

int hot_func3() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].carr[10];
    }
    return ret + sp[0].b1 + sp[0].d1;
}
```

In this case, when the program is compiled, the compiler generates a message saying that reordering the fields of the structure 'str' will improve data locality and that the suggested field order is 'a1, c1, e1, carr, b1, d1'.

For the above example, the only changes in `field_reord.c` to reorder fields of the structure 'str' as advised are the following:

```
//field_reord.c
struct str {
    int a1, c1, e1, carr[100], b1, d1;
};
...
```

Verify

The suggestion is based on the field references in the current compilation. Please make sure that the restructured code satisfies the original program semantics.

GAP Message (Diagnostic ID 30756)

Message

Split the structure '%s' into two parts to improve data locality. Frequently accessed fields are '%s'; performance may improve by putting these fields into one structure and the remaining fields into another structure. Alternatively, performance may also improve by reordering the fields of the structure. Suggested field order: '%s'.

Advice

This message is issued when both structure splitting and field reordering transformations are applicable. Structure splitting transformation is expected to lead to higher performance gains if the transformation can be successfully applied. However, field reordering transformation is usually simple enough to apply, but the downside is that the performance gain seen may be lower.

You must verify that the structure meets the requirements for applying the splitting or reordering transformation. Some of these requirements are described in the description of these individual transformations.

Example

Consider the following:

```
//str_split_reord.c
struct str {
    int a1, b1, carr[100], c1, e1;
};

#define N 1000000

struct str *sp;

void allocate_str_mem() {
    sp = malloc(N * sizeof(struct str));
}

int hot_func1() {
    int i, ret = 0;

    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret += sp[i].c1;
    }
    sp->carr[0] = ret;
```

```
    return ret;
}

int hot_func2() {
    int ret = 0, i;
    for (i = 0; i < 100000; i++) {
        ret += sp[i].a1;
        ret -= sp[i].e1;
    }
    return ret;
}

int hot_func3() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].b1;
    }
    return ret;
}
```

In this case, a message is displayed that is similar to the following:

drive: program-name: remark #30756: (DTRANS) Split the structure 'str' into two parts to improve data locality. Frequently accessed fields are 'a1, b1, c1'; performance may improve by putting these fields into one structure and the remaining fields into another structure. Alternatively, performance may also improve by reordering the fields of the structure. Suggested field order: 'a1, c1, e1, b1, carr'. ...(etc.)

If you determine it is safe to do so, you can modify the program code as shown below to split the structure 'str'. Other references to structure 'str' that are not in the current module should also be similarly modified.

```
struct str_cold {
    int carr[100], e1;
};

struct str {
    int a1, b1, c1; struct str_cold *cold_ptr;
};

#define N 1000000

struct str *sp;

void allocate_str_mem()
{
    struct str *temp;
    struct str_cold *cold_begin;
    int index;

    temp = malloc(N * sizeof(struct str) + N * sizeof(struct str_cold));
    sp = temp;
    cold_begin = (struct str_cold *) (temp + N);
    for(index = 0; index < N; index++) {
       temp[index].cold_ptr = cold_begin + index;
    }
}

int hot_func1() {
    int i, ret = 0;

    for (i = 0; i < 1000000; i++) {
```

```
        ret += sp[i].a1;
        ret += sp[i].c1;
    }
    sp->cold_ptr->carr[0] = ret;
    return ret;
}

int hot_func2() {
    int ret = 0, i;
    for (i = 0; i < 100000; i++) {
        ret += sp[i].a1
        ret -= sp[i].cold_ptr->e1;
    }
    return ret;
}

int hot_func3() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].b1;
    }
    return ret;
}
```

For the above example, the only source change required to reorder fields in structure 'str' as alternatively suggested are the following:

```
//str_split_reord.c
struct str {
    int a1, c1, e1, b1, carr[100];
};
...
```

Verify

The suggestion is based on the field references in the current compilation. Please make sure that the restructuring is applied to field references in all source files of the application, and that the restructured code satisfies the original program semantics.

GAP Message (Diagnostic ID 30757)

Message

Remove unused field(s) '%s' from the struct '%s'.

This message is emitted only with whole-program recognition.

Advice

Some unused fields were seen in a class or structure type. If the unused fields can be removed from the structure definition, it will lead to reduced memory usage and better cache utilization since the cache will no longer be filled with unused data.

The advice is based on the analysis of the source code that is seen. You must verify that the fields that are reported as unused are not accessed elsewhere in the application. You also need to be careful when removing unused fields if the code relies on the structure fields to be laid out in a specific order. As an example, if the application code uses the address of a field to access other fields, it may stop working once unused fields are removed. Note that such code is not considered valid in the first place.

Example

Consider the following:

```
//unused_field_1.c
struct str {
    int a1, b1, c1, d1, e1;
};

struct str sp[1000000];
 int hot_func1() {
    int i, ret = 0;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret += sp[i].b1;
    }
    return ret;
}

int hot_func2() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret -= sp[i].c1;
    }
    return ret;
}

int hot_func3() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].d1;
    }
    return ret;
}

main() {
    hot_func1();
    hot_func2();
    hot_func3();
}
```

In this case, if the unused fields can be removed, the only source change needed would be the following:

```
//unused_field_1.c
struct str {
    int a1, b1, c1, d1;
};
...
```

Verify

Make sure that the restructured code satisfies the original program semantics.

GAP Message (Diagnostic ID 30758)

GAP Message (Diagnostic ID 30758)

Message

Remove unused field(s) "%s" from the struct "%s".

This message is emitted even without whole-program recognition in advanced mode.

Advice

Some unused fields were seen in a class or structure type. If the unused fields can be removed from the structure definition, it will lead to reduced memory usage and better cache utilization since the cache will no longer be filled with unused data.

The advice is based on the analysis of the source code that is seen. You must verify that the fields that are reported as unused are not accessed elsewhere in the application. You also need to be careful when removing unused fields if the code relies on the structure fields to be laid out in a specific order. As an example, if the application code uses the address of a field to access other fields, it may stop working once unused fields are removed. Note that such code is not considered valid in the first place.

Example

Consider the following:

```
//unused_field_2.c
struct str {
    int a1, b1, c1, d1, e1;
};

extern struct str sp[];

int hot_func1() {
    int i, ret = 0;

    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret += sp[i].b1;
    }
    return ret;
}

int hot_func2() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret -= sp[i].c1;
    }
    return ret;
}

int hot_func3() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].d1;
    }
    return ret;
}
```

In this case, if the unused fields can be removed, the only source change needed would be the following:

```
//unused_field_2.c
struct str {
    int a1, b1, c1, d1;
};
...
```

Verify

The suggestion is based on the field references in the current compilation. Please make sure that there are no references to these fields across the entire application.

GAP Message (Diagnostic ID 30757)

GAP Message (Diagnostic ID 30759)

Message

Remove unused field(s) '%s' from the struct '%s'. The fields: '%s' were conservatively assumed by the compiler as referenced since their address is taken.

This message is emitted only with whole-program recognition.

Advice

Some unused fields were seen in a class or structure type. If the unused fields can be removed from the structure definition, it will lead to reduced memory usage and better cache utilization since the cache will no longer be filled with unused data.

You must verify that the fields that are reported as unused are not accessed elsewhere in the application. You also need to be careful when removing unused fields if the code relies on the structure fields to be laid out in a specific order. For example, if the application code uses the address of a field to access other fields, it may stop working once unused fields are removed. Note that such code is not considered valid in the first place.

The unused field analysis considers address taken fields as used. It will report address taken fields also when reporting any unused fields.

Example

Consider the following:

```
//unused_field_3.c
struct str {
    int a1, b1, c1, d1, e1, f1;
};

struct str sp[1000000];

int hot_func1() {
    int i, ret = 0;

    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret += sp[i].b1;
    }
    return ret;
}
```

```
int hot_func2() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret -= sp[i].c1;
    }
    return ret;
}

int *gip;

int hot_func3() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].d1;
    }
    gip = &(sp->f1);
    return ret;
}

int main() {
    hot_func1();
    hot_func2();
    hot_func3();
}
```

The above code will cause a message to be displayed that is similar to the following:

program-name: remark #30759: (DTRANS) Remove unused field(s) 'e1' from the struct 'str'. The fields: 'f1' were conservatively assumed by the compiler as referenced since their address is taken... (etc.)

In this case, if the unused fields can be removed, the only source change needed would be the following:

```
//unused_field_3.c
struct str {
    int a1, b1, c1, d1, f1;
};
...
```

Verify

Make sure that the restructured code satisfies the original program semantics.

Message

Remove unused field(s) '%s' from the struct '%s'. The fields: '%s' were conservatively assumed by the compiler as referenced since their address is taken.

This message is emitted even without whole-program recognition in advanced mode.

Advice

Some unused fields were seen in a class or structure type. If the unused fields can be removed from the structure definition, it will lead to reduced memory usage and better cache utilization since the cache will no longer be filled with unused data.

You must verify that the fields that are reported as unused are not accessed elsewhere in the application. You also need to be careful when removing unused fields if the code relies on the structure fields to be laid out in a specific order.

For example, if the application code uses the address of a field to access other fields, it may stop working once unused fields are removed. Note that such code is not considered valid in the first place.

The unused field analysis considers address taken fields as used. It will report address taken fields also when reporting any unused fields.

Example

Consider the following:

```
//unused_field_4.c
struct str {
    int a1, b1, c1, d1, e1, f1;
};

extern struct str sp[];

int hot_func1() {
    int i, ret = 0;

    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret += sp[i].b1;
    }
    return ret;
}

int hot_func2() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].a1;
        ret -= sp[i].c1;
    }
    return ret;
}

int *gip;

int hot_func3() {
    int ret = 0, i;
    for (i = 0; i < 1000000; i++) {
        ret += sp[i].d1;
    }

    gip = &(sp->f1);
    return ret;
}
```

The above code will cause a message to be displayed that is similar to the following:

drive: program-name: remark #30760: (DTRANS) Remove unused field(s) 'e1' from the struct 'str'. The fields: 'f1' were conservatively assumed by the compiler as referenced since their address is taken. ...(etc.)

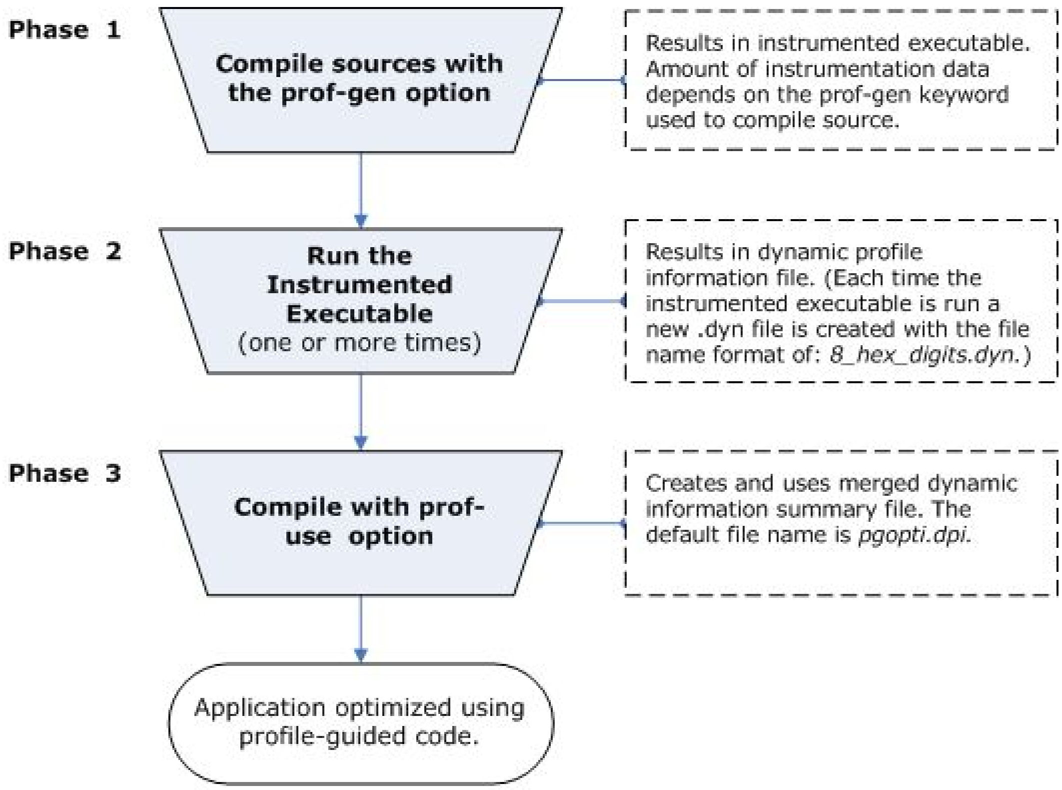
GAP Message (Diagnostic ID 30759)

Profile-Guided Optimization (PGO)

Profile-guided Optimization (PGO) improves application performance by shrinking code size, reducing branch mispredictions, and reorganizing code layout to reduce instruction-cache problems. PGO provides information to the compiler about areas of an application that are most frequently executed. By knowing these areas, the compiler is able to be more selective and specific in optimizing the application.

PGO consists of three phases or steps.

1. Instrument the program. The compiler creates and links an instrumented program from your source code and special code from the compiler.
2. Run the instrumented executable. Each time you execute the instrumented code, the instrumented program generates a dynamic information file, which is used in the final compilation.
3. Final compilation. When you compile a second time, the dynamic information files are merged into a summary file. Using the summary of the profile information in this file, the compiler attempts to optimize the execution of the most heavily traveled paths in the program.



See Profile-guided Optimization Options for information about the supported options and Profile an Application for specific details about using PGO from the command line.

PGO provides the following benefits:

- Use profile information for register allocation to optimize the location of spill code.
- Improve branch prediction for indirect function calls by identifying the most likely targets. Some processors have longer pipelines, which improves branch prediction and translates into high performance gains.
- Detect and do not vectorize loops that execute only a small number of iterations, reducing the run time overhead that vectorization might otherwise add.

Interprocedural optimization (IPO) and PGO can affect each other; using PGO can often enable the compiler to make better decisions about inline function expansion, which increases the effectiveness of interprocedural optimizations. Unlike other optimizations, such as those strictly for size or speed, the results of IPO and PGO vary. This variability is due to the unique characteristics of each program, which often include different profiles and different opportunities for optimizations.

Performance Improvements with PGO

PGO works best for code with many frequently executed branches that are difficult to predict at compile time. An example is the code with intensive error-checking in which the error conditions are false most of the time. The infrequently executed (cold) error-handling code can be relocated so the branch is rarely predicted incorrectly. Minimizing cold code interleaved into the frequently executed (hot) code improves instruction cache behavior.

When you use PGO, consider the following guidelines:

- Minimize changes to your program after you execute the instrumented code and before feedback compilation. During feedback compilation, the compiler ignores dynamic information for functions modified after that information was generated. If you modify your program, the compiler can issue a warning that the dynamic information does not correspond to a modified function when PGO remarks are enabled or found in the optimization report.

- Repeat the instrumentation compilation if you make many changes to your source files after execution and before feedback compilation.
- Know the sections of your code that are the most heavily used. If the data set provided to your program is very consistent and displays similar behavior on every execution, then PGO can probably help optimize your program execution.
- Different data sets can result in different algorithms being called. The difference can cause the behavior of your program to vary for each execution. In cases where your code behavior differs greatly between executions, PGO may not provide noticeable benefits. If it takes multiple data sets to accurately characterize application performance, execute the application with all data sets then merge the dynamic profiles; this technique should result in an optimized application.

You must insure that the benefit of the profiled information is worth the effort required to maintain up-to-date profiles.

Profile-Guided Optimization via Hardware Counters

A lightweight profiling mechanism can be used to achieve many of the benefits of instrumentation-based profiling, but without the overhead of inserting instrumentation into the application binary. This mode of operation can be beneficial in cases where increased code/data size or changes in runtime due to instrumentation may make regular Performance-Guided Optimization (PGO) infeasible. This approach requires the use of Intel® VTune™ Profiler to collect information from the hardware counters. The information is collected with minimal overhead, and combined with debug information produced by the compiler to identify the primary code path for optimizations.

Follow these steps to use this method:

1. Compile the application with the option `prof-gen-sampling`.

   This option instructs the compiler to generate additional debug information for the application, which is used to map the information collected by the hardware counters to a specific source code. Using this option does not affect the generated instruction sequence in the way that instrumented PGO does. Optimizations may be enabled during this build, but it is recommended that you disable function inlining.
2. Run the generated executable on one or more representative workloads with the Intel VTune Profiler tool:

```
<installation-root>/bin64/amplxe-pgo-report.sh <your application and command line>
```

   Additional information regarding options for data collection can be found in the Intel VTune Profiler documentation. This step generates files in the form: `r`*`NNN`*`pgo_icc.pgo` (where *`NNN`* is a three digit number). These files are used as input in the next steps.
3. Merge the report files produced during step 2.

   The tool `profmergesampling` can be used to produce an indexed file of results that speeds up processing data during the next step.

```
profmergesampling -file <input-file[:input_file]*> -out <output_name>
```

4. Compile the application with the option `prof-use-sampling:input-file[:input_file]*`

   In this step, one or more result files produced during step 2 (or an indexed file from step 3) can be fed into the compiler to direct the optimizations.

Profile an Application with Instrumentation

Profiling an application includes the following three phases:

- Instrumentation compilation and linking
- Instrumented execution
- Feedback compilation

This topic provides detailed information on how to profile an application by providing sample commands for each of the three phases (or steps).

1. Instrumentation compilation and linking

Use `[Q]prof-gen` to produce an executable with instrumented information included. Use `/Qcov-gen` (Windows) option to obtain minimum instrumentation only for code coverage.

Operating System	Commands
Linux and macOS	`icpc -prof-gen -prof-dir/usr/profiled a1.cpp a2.cpp a3.cpp` `icpc a1.o a2.o a3.o`
Windows	`icl /Qprof-gen /Qprof-dirc:\profiled a1.cpp a2.cpp a3.cpp` `icl a1.obj a2.obj a3.obj`
Windows	`icl /Qcov-gen /Qcov-dirc:/cov_data a1.cpp a2.cpp a3.cpp` `icl a1.obj a2.obj a3.obj`

Use the `[Q]prof-dir` or `/Qcov-dir` (Windows) option if the application includes the source files located in multiple directories; using the option insures the profile information is generated in one consistent place. The example commands demonstrate how to combine these options on multiple sources.

The compiler gathers extra information when you use the `-prof-gen=srcpos` (Linux and macOS) or `/Qprof-gen:srcpos` (Windows) option; however, the extra information is collected to provide support for specific Intel tools, including the code coverage Tool. If you do not expect to use such tools, do not specify `-prof-gen=srcpos` (Linux and macOS) or `/Qprof-gen:srcpos` (Windows); the extended option does not provide better optimization and could slow parallel compile times. If you are interested in using the instrumentation only for code coverage, use the `/Qcov-gen` (Windows) option, instead of the `/Qprof-gen:srcpos` (Windows) option, to minimize instrumentation overhead.

PGO data collection is optimized for collecting data on serial applications at the expense of some loss of precision on areas of high parallelism. However, you can specify the `threadsafe` keyword with the `-prof-gen` (Linux* and macOS) or the `/Qprof-gen` (Windows) compiler option for files or applications that contain parallel constructs using OpenMP* features, for example. Using the `threadsafe` keyword produces instrumented object files that support the collection of PGO data on applications that use a high level of parallelism but may increase the overhead for data collection.

NOTE
Unlike serial programs, parallel programs using OpenMP* may involve dynamic scheduling of code paths, and counts collected may not be perfectly reproducible for the same training data set.

2. Instrumented execution

Run your instrumented program with a representative set of data to create one or more dynamic information files.

Operating System	Command
Linux and macOS	`./a1.out`
Windows	`a1.exe`

Executing the instrumented applications generates a dynamic information file that has a unique name and .dyn suffix. A new dynamic information file is created every time you execute the instrumented program.

You can run the program more than once with different input data.

By default, the `.dyn` filename follows this naming convention: `<timestamp>_<pid>.dyn`. The `.dyn` file is either placed into a directory specified by an environment variable, a compile-time specified directory, or the current directory.

To make it easy to distinguish files from different runs, you can specify a prefix for the `.dyn` filename in the environment variable, `INTEL_PROF_DYN_PREFIX`. In such a case, executing the instrumented application generates a `.dyn` filename as follows: `<prefix>_<timestamp>_<pid>.dyn`, where `<prefix>` is the identifier that you have specified. Be sure to set the `INTEL_PROF_DYN_PREFIX` environment variable prior to starting your instrumented application.

NOTE
The value specified in `INTEL_PROF_DYN_PREFIX` environment variable must not contain `< > : " / \ | ? *` characters. The default naming scheme will be used if an invalid prefix is specified.

3. Feedback compilation

Before this step, copy all .dyn and .dpi files into the same directory. Compile and link the source files with `[Q]prof-use`; the option instructs the compiler to use the generated dynamic information to guide the optimization:

Operating System	Examples
Linux and macOS	`icpc -prof-use -ipo -prof-dir/usr/profiled a1.cpp a2.cpp a3.cpp`
Windows	`icl /Qprof-use /Qipo /Qprof-dir:c:\profiled a1.cpp a2.cpp a3.cpp`

This final phase compiles and links the sources files using the data from the dynamic information files generated during instrumented execution (phase 2).

In addition to the optimized executable, the compiler produces a pgopti.dpi file.

Most of the time, you should specify the default optimizations,`O2`, for phase 1, and specify more advanced optimizations, `[Q]ipo`, during the phase 3 (final) compilation. The example shown above used`O2` in step 1 and`[Q]ipo` in step 3.

NOTE
The compiler ignores the `[Q]ipo` or `[Q]ip` option during phase 1 with `[Q]prof-gen`.

Profile-Guided Optimization Report

The PGO report can help identify where and how the compiler used profile information to optimize the source code. The PGO report can also identify where profile information was discarded due to source code changes made between the time of instrumentation and feedback steps. The PGO report is most useful when combined with the PGO compilation steps outlined in the topic, Profile an Application with Instrumentation. Without the profiling data generated during the application profiling process the report will generally not provide useful information.

Combine the final PGO step with the reporting options by including `-prof-use` (Linux* and macOS) or `/Qprof-use` (Windows*). The following syntax examples demonstrate how to run the report using the combined options.

Operating System	Syntax Examples
Linux*	`icpc -prof-use -qopt-report-phase=pgo pgotools_sample.c`
macOS	`icpc -prof-use -qopt-report-phase=pgo pgotools_sample.c`
Windows*	`icl /Qprof-use /Qopt-report-phase:pgo pgotools_sample.c`

By default the PGO report generates a medium level of detail (where the `[q or Q]opt-report` argument *n*=2). You can use the `-qopt-report=`*n* (Linux and macOS) or `/Qopt-report:`*n* option along with the `[q or Q]opt-report-phase` option if you want a greater or lesser level of diagnostic detail.

The output, by default, comes out to a file with the same name as the object file but with an `.optrpt` extension and is written into the same directory as the object file. Using the entries in the example above, the output file will be `pgotools_sample.optrpt`. Use the `-qopt-report-file` (Linux and macOS) or the `/Qopt-report-file` (Windows) option to specify any other name for the output file that captures the report results, or to specify that the output should go to `stdout` or `stderr`.

Profile an Application

PGO API Support

The Profile-Guided Optimizations (PGO) API lets you control the generation of profile information during the instrumented execution phase of profile-guided optimizations.

A set of functions and an environment variable comprise the PGO API. The remaining topics in this section describe the associated functions and environment variables.

The compiler sets a `define` for the `_PGO_INSTRUMENT` pre-processor macro when you compile with `[Q]prof-gen` options, to instrument your code. Without instrumentation, the PGO API functions cannot provide PGO API support.

Normally, profile information is generated by an instrumented application when it terminates by calling the standard `exit()` function.

To ensure that profile information is generated, the functions described in this section may be necessary or useful in the following situations:

- The instrumented application exits using a non-standard exit routine.
- The instrumented application is a non-terminating application: `exit()` is never called.
- The application requires control of when the profile information is generated.

You can use the PGO API functions in your application by including the `pgouser.h` header file at the top of any source file where the functions may be used.

Example

```
#include <pgouser.h>
```

NOTE
You do not need to remove the PGO API functions from your code when you have completed the instrumentation step. Changes to the source code at this stage could inhibit obtaining profile data feedback on the routines that were modified. For the instrumentation step (using `-[Q]prof-gen` or `-[Q]prof-gen:<aug>` option, where <aug> can be srcpos, globdata, or default), the definition for the `_PGO_INSTRUMENT` macro is automatically set, allowing instrumentation library routines to be used. For the production step (using `-[Q]prof-use` option), the definition for the `_PGO_INSTRUMENT` macro is removed, allowing profile data to be fed back.

The Profile IGS Environment Variables

The environment variable for PGO API is `INTEL_PROF_DUMP_INTERVAL`. This environment variable may be used to initiate Interval Profile Dumping in an instrumented user application.

The environment variable `INTEL_PROF_DUMP_CUMULATIVE` can be used to provide additional control over the internal profiling dumping behavior.

The environment variable, `INTEL_PROF_DYN_PREFIX`, allows specifying a prefix string that is used for naming the `.dyn` files. If this variable is defined then the `.dyn` files will be named as `<prefix>_<timestamp>_<pid>.dyn`, instead of the default naming convention of `<timestamp>_<pid>.dyn`. This can be useful for identifying `.dyn` files produced by specific training sets.

[Q]prof-gen

Resetting Profile Information

The `_PGOPTI_Prof_Reset_All()` function clears the profile information collected by the instrumented application. The prototype of the function call is listed below.

During a run of an instrumented executable, a segment is maintained for each routine executed during that run, storing the following information:

- Number of times each basic block in the routine is executed
- Specific values observed at each data point undergoing value-profiling
- Number of times each of these values are observed

When the _PGOPTI_Prof_Reset() function is called, the basic block execution count for each basic block is set to 0, and the value-profiling information is reset to indicate that no values were observed at any data point.

Syntax
`void _PGOPTI_Prof_Reset_All(void);`

The older version of this function, `_PGOPTI_Prof_Reset()`, is deprecated.

When `_PGOPTI_Prof_Reset_All()` function is called, it insures that all the counters within the main application and all the instrumented shared libraries are cleared. All the counters for block execution counts and value profiling information is reset to 0.

NOTE
For routines that were in progress when the reset call was made, the counts for portions of the routine that executed following the call to the reset function may have higher counts than portions of the routine that executed prior to the reset call.

Dumping Profile Information

The `_PGOPTI_Prof_Dump_All()` function dumps the profile information collected by the instrumented application. The prototype of the function call is listed below.

Syntax
`void _PGOPTI_Prof_Dump_All(void);`

An older version of this function, `_PGOPTI_Prof_Dump()`, is deprecated and no longer used.

The new function, `_PGOPTI_Prof_Dump_All()`, operates much like the deprecated function, except on Linux* operating systems, when it is used in connection with shared libraries (.so). When `_PGOPTI_Prof_Dump_All()` is called, it insures that a .dyn file is created for all shared libraries needing to create a .dyn file. Use `_PGOPTI_Prof_Dump_All()` on Linux OS to insure portability and correct functionality.

The profile information is generated in a `.dyn` file (generated in phase 2 of PGO).

The environment variables that affect the `_PGOPTI_Prof_Dump_All()` function are `PROF_DIR`, `COV_DIR`, `PROF_DPI`, `and COV_DPI`. Set the `PROF_DIR or COV_DIR` environment variable to specify the directory to which the .dyn file must be stored. Alternately, you can use the `-[Q]prof_dir` compiler option, when building with `-[Q]prof-gen`, to specify this directory without setting the `PROF_DIR or COV_DIR` variable. Set the `PROF_DPI` or `COV_DPI` environment variables to specify an alternative .dpi filename. The default filename is `pgopti.dpi`. You can also use the `-prof_dpi` profmerge tool option, when merging the .dyn files, to specify the filename for the summary .dpi file.

Recommended Usage

If your application does not use a standard exit() call, insert a single call to this function in the body of the function that terminates the user application. Normally, `_PGOPTI_Prof_Dump_All()` should be called just once. It is also possible to use this function in conjunction with _PGOPTI_Prof_Reset_All() function to generate multiple .dyn files (presumably from multiple sets of input data).

> **NOTE**
> If the data is not reset between the dumps with a call to the _PGOPTI_Prof_Reset_All() function, the counters will continue accumulating data, resulting in the subsequent .dyn file containing data that was previously dumped.

Example

```
#include <pgouser.h>
void process_data(int foo) {}
int  get_input_data() { return 1; }
int  main(void)
{
// Selectively collect profile information for the portion
// of the application involved in processing input data.
  int input_data = get_input_data();
  while (input_data) {
    _PGOPTI_Prof_Reset_All();
    process_data(input_data);
    _PGOPTI_Prof_Dump_All();
    input_data = get_input_data();
```

Example

```
  }
  return 0;
}
```

Interval Profile Dumping

The `_PGOPTI_Set_Interval_Prof_Dump()` function activates Interval Profile Dumping and sets the approximate frequency at which dumps occur. This function is used in non-terminating applications.

The prototype of the function call is listed below.

Syntax

```
void _PGOPTI_Set_Interval_Prof_Dump(int interval);
```

This function is used in non-terminating applications.

The `interval` parameter specifies the time interval at which profile dumping occurs and is measured in milliseconds. For example, if interval is set to 5000, then a profile dump and reset will occur approximately every 5 seconds. The interval is approximate because the time-check controlling the dump and reset is only performed upon entry to any instrumented function in your application.

Setting the interval to zero or a negative number will disable interval profile dumping, and setting a very small value for the interval may cause the instrumented application to spend nearly all of its time dumping profile information. Be sure to set interval to a large enough value so that the application can perform actual work and substantial profile information is collected.

The following example demonstrates one way of using interval profile dumping in non-terminating code.

Example

```
#include <stdio.h>
// The next include is to access
// _PGOPTI_Set_Interval_Prof_Dump_All
#include <pgouser.h>
int returnValue() { return 100; }
int main() {
  int ans;
  printf("CTRL-C to quit.\n");
  _PGOPTI_Set_Interval_Prof_Dump(5000);
  while (1)
    ans = returnValue();
}
```

You can compile the code shown above by entering commands similar to the following:

Operating System	Example
Linux*	`icc -prof-gen -o intrumented_number number.c`
macOS	`icc -prof-gen -o intrumented_number number.c`
Windows*	`icl /Qprof-gen /Feinstrumented_number number.c`

When compiled, the code shown above will dump profile information a `.dyn` file about every five seconds until the program is ended.

You can use the profmerge and proforder Tools tool to merge the `.dyn` files.

Recommended usage

Call this function at the start of a non-terminating user application to initiate interval profile dumping. Note that an alternative method of initiating interval profile dumping is by setting the environment variable INTEL_PROF_DUMP_INTERVAL to the desired interval value prior to starting the application.

Using interval profile dumping, you should be able to profile a non-terminating application with minimal changes to the application source code.

To control the behavior during dumping, you may use the environment variable INTEL_PROF_DUMP_CUMULATIVE. When `INTEL_PROF_DUMP_INTERVAL` or the API routine `_PGOPTI_SET_INTERVAL_PROF_DUMP` are used without `INTEL_PROF_DUMP_CUMULATIVE`, the counters are reset after each dump, and a new `.dyn` file will be created containing the data collected during each interval. This may result in a potentially large number of `.dyn` files that need to be stored and merged together by profmerge.

When `INTEL_PROF_DUMP_CUMULATIVE` is set (to any value), the `.dyn` file dump will be created at a specified interval as before, but the data will not be reset following the dump, and only the most recent `.dyn` file will be kept on the file system. This allows for the ability to create a `.dyn` file for a non-terminating application that contains all the accumulated counts to that point, but without the need for storage and merging of a large set of .dyn files.

Resetting the Dynamic Profile Counters

The `_PGOPTI_Prof_Reset()` function resets the dynamic profile counters. The prototype of the function call is listed below.

Syntax
`void _PGOPTI_Prof_Reset(void);`

This function is now deprecated. See _PGOPTI_Prof_Reset_All() function, which can be used instead.

One of the activities performed under profile-guided optimization is value-profiling. With value-profiling, the compiler inserts instrumentation to obtain a sample of the variable values in the program. Based upon this sampling, the compiler optimizes the user's code using frequently observed values.

In effect, during a run of an instrumented executable, the segment maintained for each routine executed during that run stores the following information:

- Number of times each basic block in the routine is executed
- Specific values observed at each data point undergoing value-profiling
- Number of times each of these values are observed

When the `_PGOPTI_Prof_Reset()` function is called, the basic block execution count for each basic block is set to 0, and the value-profiling information is reset to indicate that no values were observed at any data point.

Recommended Usage

Use this function to clear the profile counters prior to collecting profile information on a section of the instrumented application. See the example under Dumping Profile Information.

Dumping and Resetting Profile Information

The `_PGOPTI_Prof_Dump_And_Reset()` function dumps the profile information to a new .dyn file and then resets the dynamic profile counters. Then the execution of the instrumented application continues.

The prototype of the function call is listed below.

Syntax
`void _PGOPTI_Prof_Dump_And_Reset(void);`

This function is used in non-terminating applications and may be called more than once. Each call will dump the profile information to a new .dyn file.

Recommended Usage

Periodic calls to this function enables a non-terminating application to generate one or more profile information files (`.dyn` files). These files are merged during the feedback phase of profile-guided optimizations. The direct use of this function enables your application to control precisely when the profile information is generated.

Getting Coverage Summary Information on Demand

This API is supported only on Linux* OS for C/C++ applications.

The `_PGOPTI_Get_Coverage_Info()` function gets the basic-block and line coverage percentage for each instrumented file while the application is running.

The prototype of the function call is given below.

Syntax
`int _PGOPTI_Get_Coverage_Info(PGOPTI_COVERAGE_SUMMARY *coverage_array);`

This API provides on-demand coverage information for all the files that get profiled. The coverage information is stored in a dynamically allocated array of structures, a pointer to which is returned in the argument *coverage_array*. The return value of the call is the number of elements in this array.

You can use the coverage information as needed but you are responsible for freeing up the dynamically allocated coverage array.

You can also choose to print the on-demand coverage information onto the terminal screen as shown in the example below.

```
#include <pgouser.h>
void Coverage_Summary(void)
{
    int index, num_files;
    PGOPTI_COVERAGE_SUMMARY coverage_array, curp;
    // Get coverage summary information and print it out
    num_files =  _PGOPTI_Get_Coverage_Info(&coverage_array);
    for (index = 0; index < num_files; index++) {
        curp = &coverage_array[index];
        printf( "%s ", curp->file_name);
        printf( "Block coverage percent: %u, ", curp->coverage_percent);
        printf( "Line coverage percent: %u\n", curp->line_coverage_percent);
        free(curp->file_name);
    }
    if (num_files > 0) {
       free(coverage_array);
    }}
```

High-Level Optimization (HLO)

High-level Optimizations (HLO) exploit the properties of source code constructs (for example, loops and arrays) in applications developed in high-level programming languages. While the default optimization level, option `O2` , performs some high-level optimizations, specifying the `O3` option provides the best chance for performing loop transformations to optimize memory accesses.

> **NOTE**
> Loop optimizations may result in calls to library routines that can result in additional performance gain on Intel® microprocessors than on non-Intel microprocessors. The optimizations performed can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS), or `[Q]x` options. Additional HLO transformations may be performed for Intel® microprocessors than for non-Intel microprocessors.

Within HLO, loop transformation techniques include:

- Loop Permutation or Interchange
- Loop Distribution
- Loop Fusion
- Loop Unrolling
- Data Prefetching
- Scalar Replacement
- Unroll and Jam
- Loop Blocking or Tiling
- Partial-Sum Optimization
- Predicate Optimization
- Loop Reversal
- Profile-Guided Loop Unrolling
- Loop Peeling
- Data Transformation: Malloc Combining and Memset Combining, Memory Layout Change
- Loop Rerolling
- Memset and Memcpy Recognition
- Statement Sinking for Creating Perfect Loopnests
- Multiversioning: Checks include Dependency of Memory References, and Trip Counts
- Loop Collapsing

Interprocedural Optimization

Interprocedural Optimization (IPO) is an automatic, multi-step process that allows the compiler to analyze your code to determine where you can benefit from specific optimizations.

The compiler may apply the following optimizations:

- Address-taken analysis
- Array dimension padding
- Alias analysis
- Automatic array transposition
- Automatic memory pool formation
- C++ class hierarchy analysis
- Common block variable coalescing
- Common block splitting

- Constant propagation
- Dead call deletion
- Dead formal argument elimination
- Dead function elimination
- Formal parameter alignment analysis
- Forward substitution
- Indirect call conversion
- Inlining
- Mod/ref analysis
- Partial dead call elimination
- Passing arguments in registers to optimize calls and register usage
- Points-to analysis
- Routine key-attribute propagation
- Specialization
- Stack frame alignment
- Structure splitting and field reordering
- Symbol table data promotion
- Un-referenced variable removal
- Whole program analysis

IPO Compilation Models

IPO supports two compilation models - single-file compilation and multi-file compilation.

Single-file compilation uses the `[Q]ip` compiler option, and results in one, real object file for each source file being compiled. During single-file compilation the compiler performs inline function expansion for calls to procedures defined within the current source file.

The compiler performs some single-file interprocedural optimization at the `O2` default optimization level; additionally the compiler may perform some inlining for the `O1` optimization level, such as inlining functions marked with inlining pragmas or attributes (GNU C and C++) and C++ class member functions with bodies included in the class declaration.

Multi-file compilation uses the `[Q]ipo` option, and results in one or more mock object files rather than normal object files. (See the *Compilation* section below for information about mock object files.) Additionally, the compiler collects information from the individual source files that make up the program. Using this information, the compiler performs optimizations across functions and procedures in different source files.

> **NOTE**
> Inlining and other optimizations are improved by profile information. For a description of how to use IPO with profile information for further optimization, see Profile an Application.

Compiling with IPO

As each source file is compiled with IPO, the compiler stores an intermediate representation (IR) of the source code in a mock object file. The mock object files contain the IR instead of the normal object code. Mock object files can be ten times or more larger than the size of normal object files.

During the IPO compilation phase only the mock object files are visible.

Linking with IPO

When you link with the `[Q]ipo` compiler option the compiler is invoked a final time. The compiler performs IPO across all mock object files. The mock objects must be linked with the compiler or by using the Intel® linking tools. While linking with IPO, the compiler and other linking tools compile mock object files as well as invoke the real/true object files linkers provided on the user's platform.

Link-time optimization using the `-ffat-lto-objects` compiler option is provided for GCC compatibility. During IPO compilation, you can specify `-ffat-lto-objects` option, for the compiler to generate a fat link-time optimization (LTO) object that has both a real/true object and a discardable intermediate language section. This enables both link-time optimization (LTO) linking and normal linking.

You can specify the `-fno-fat-lto-objects` option for the compiler to generate a link-time optimization (LTO) object that only has a discardable intermediate language section; no real/true object is generated. These files are inserted into archives in the form in which they were created. Using this option may improve compilation time and save space for objects.

If you use `ld` rather than `xild` to link objects or `ar` instead of `xiar` to create an archive, the real/true object, generated during fat link-time optimization guarantees that there will be no impediment to linking/building the archive. However, cross-file optimizations are lost in this case. The extra true object also takes additional space and takes compile time to generate it, so using `-fno-fat-lto-objects` compiler option is an advantage provided that you link the IPO mock object files with `xild` and archive them with `xiar`.

Whole Program Analysis

The compiler supports a large number of IPO optimizations that can be applied or have its effectiveness greatly increased when the whole program condition is satisfied.

During the analysis process, the compiler reads all Intermediate Representation (IR) in the mock file, object files, and library files to determine if all references are resolved and whether or not a given symbol is defined in a mock object file. Symbols that are included in the IR in a mock object file for both data and functions are candidates for manipulation based on the results of whole program analysis.

There are two types of whole program analysis - object reader method and table method. Most optimizations can be applied if either type of whole program analysis determines that the whole program conditions exists; however, some optimizations require the results of the object reader method, and some optimizations require the results of table method.

Object reader method

In the object reader method, the object reader emulates the behavior of the native linker and attempts to resolve the symbols in the application. If all symbols are resolved, the whole program condition is satisfied. This type of whole program analysis is more likely to detect the whole program condition.

Table method

In the table method the compiler analyzes the mock object files and generates a call-graph.

The compiler contains detailed tables about all of the functions for all important language-specific libraries, like `libc`. In this second method, the compiler constructs a call-graph for the application. The compiler then compares the function table and application call-graph. For each unresolved function in the call-graph, the compiler attempts to resolve the calls by finding an entry for each unresolved function in the compiler tables. If the compiler can resolve the functions call, the whole program condition exists.

x, Qx

Use Interprocedural Optimization

Use Interprocedural Optimization

This topic discusses how to use IPO from the command line.

Compiling and Linking Using IPO

To enable IPO, you first compile each source file, then link the resulting source files.

Linux and macOS

1. Compile your source files with the `ipo` compiler option:

```
icpc -ipo -c a.cpp b.cpp c.cpp
```

   The command produces `a.o`, `b.o`, and `c.o` object files.

   Use the `c` compiler option to stop compilation after generating `.o` object files. The output files contain compiler intermediate representation (IR) corresponding to the compiled source files.
2. Link the resulting files. The following example command will produce an executable named `app`:

```
icpc -ipo -o app a.o b.o c.o
```

   The command invokes the compiler on the objects containing IR and creates a new list of objects to be linked. Alternately, you can use the `xild` tool, with the appropriate linking options.

The separate compile and link commands from the previous steps can be combined into a single command, for example:

```
icpc -ipo -o app a.cpp b.cpp c.cpp
```

The icpc command, shown in the examples, calls `GCC ld` to link the specified object files and produce the executable application, which is specified by the `-o` option.

Windows

1. Compile your source files with the `/Qipo` compiler option:

```
icl /Qipo /c a.cpp b.cpp c.cpp
```

   The command produces `a.obj`, `b.obj`, and `c.obj` object files.

   Use the `c` compiler option to stop compilation after generating `.obj` files. The output files contain compiler intermediate representation (IR) corresponding to the compiled source files.
2. Link the resulting files. The following example command will produce an executable named `app`:

```
icl /Qipo /Feapp a.obj b.obj c.obj
```

   The command invokes the compiler on the objects containing IR and creates a new list of objects to be linked. Alternately, you can use the `xilink` tool, with the appropriate linking options.

The separate compile and link commands from the previous steps can be combined into a single command, for example:

```
icl /Qipo /Feapp a.cpp b.cpp c.cpp
```

The icl command, shown in the examples, calls `link.exe` to link the specified object files and produce the executable application, which is specified by the `/Fe` option.

NOTE
Linux: Using icpc allows the compiler to use standard C++ libraries automatically; icc will not use the standard C++ libraries automatically.

macOS: Using icc/icpc commands allows the compiler to use libc++ libraries, by default. You can switch to using the GNU implementation of the standard C++ library using the `-stdlib=`*libstdc++* compiler option.

The Intel linking tools emulate the behavior of compiling at `-O0` (Linux and macOS) and `/Od` (Windows) option.

If multiple file IPO is applied to a series of object files, no one which are mock object files, no multi-file IPO is performed. The object files are simply linked with the linker.

Capturing Intermediate IPO Output

The `[Q]ipo-c` and `[Q]ipo-S` compiler options are useful for analyzing the effects of multi-file IPO, or when experimenting with multi-file IPO between modules that do not make up a complete program.

- Use the `[Q]ipo-c` compiler option to optimize across files and produce an object file. The option performs optimizations as described for the `[Q]ipo` option but stops prior to the final link stage, leaving an optimized object file. The default name for this file is `ipo_out.o` (Linux and macOS) or `ipo_out.obj` (Windows).
- Use the `[Q]ipo-S` compiler option to optimize across files and produce an assembly file. The option performs optimizations as described for `[Q]ipo`, but stops prior to the final link stage, leaving an optimized assembly file. The default name for this file is `ipo_out.s` (Linux) or `ipo_out.asm` (Windows).

For both options, you can use the `-o` (Linux and macOS) or `/Fe` (Windows) option to specify a different name.

These options generate multiple outputs if multi-object IPO is being used. The name of the first file is taken from the value of the `-o` (Linux and macOS) or `/Fe` (Windows) option.

The names of subsequent files are derived from the first file with an appended numeric value to the file name. For example, if the first object file is named `foo.o` (Linux and macOS) or `foo.obj` (Windows), the second object file will be named `foo1.o` or `foo1.obj`.

You can use the object file generated with the `[Q]ipo-c` option, but you will not get the full benefit of whole program optimizations if you use this option.

The object file created using the `[Q]ipo-c` option is a real object file, in contrast to the mock file normally generated using IPO; however, the generated object file is significantly different than the mock object file. Whole program optimizations, which require a knowledge of how the real object file will be linked in with other files to produce and object, are not applied.

The compiler generates a message indicating the name of each object or assembly file it generates. These files can be added to the real link step to build the final application.

Using -auto-ilp32 (Linux OS) or /Qauto-ilp32 (Windows OS) Option

On Linux systems based on Intel® 64 architecture, the `auto-ilp32` option has no effect unless you specify SSE3 or a higher suffix for the `x` option.

Performance and Large Program Considerations

IPO-related Performance Issues

There are some general optimization guidelines for using IPO that you should keep in mind:

- Using IPO on very large programs might trigger internal limits of other compiler optimization phases.
- Combining IPO and PGO can be a key technique for optimizing C++ applications. The following compiler options may result in performance gains: `O3`, `[Q]ipo`, and `[Q]prof-use`
- Applications where the compiler does not have sufficient intermediate representation (IR) coverage to do whole program analysis might not perform as well as those where IR information is complete.

In addition to these general guidelines, there are some practices to avoid while using IPO. The following list summarizes the activities to avoid:

- Do not use the link phase of an IPO compilation using mock object files produced for your application by a different compiler. Intel® compilers cannot inspect mock object files generated by other compilers for optimization opportunities.
- Do not link mock files with the `[Q]prof-use` compiler option unless the mock files were also compiled with the `[Q]prof-use` compiler option.
- Update make files to call the appropriate Intel linkers when using IPO from scripts. For Linux and macOS, replace all instances of `ld` with `xild`; for Windows, replace all instances of `link` with `xilink`.

IPO for Large Programs

In most cases, IPO generates a single true object file for the link-time compilation. This behavior is not optimal for very large programs, perhaps even making it impossible to use `[Q]ipo` compiler option on the application.

The compiler provides two methods to avoid this problem. The first method is an automatic size-based heuristic, which causes the compiler to generate multiple true object files for large link-time compilations. The second method is to manually instruct the compiler to perform multi-object IPO.

- Use the `[Q]ipo`*N* compiler option and pass an integer value in the place of *N*.
- Use the `[Q]ipo-separate` compiler option.

  The number of true object files generated by the link-time compilation is invisible to you unless the `[Q]ipo-c` or `[Q]ipo-S` compiler option is used.

Regardless of the method used, it is best to use the compiler defaults first and examine the results. If the defaults do not provide the desired results then experiment with generating a different number of object files.

You can use the `[Q]ipo-jobs` compiler option to control the number of processes, or jobs, executed during parallel IPO builds.

Using [Q]ipo*N* to Create Multiple Object Files

If you specify `[Q]ipo0`, which is the same as not specifying a value, the compiler uses heuristics to determine whether to create one or more object files based on the expected size of the application. The compiler generates one object file for small applications, and two or more object files for large applications. If you specify any value greater than 0, the compiler generates that number of object files, unless the value you pass a value that exceeds the number of source files. In that case, the compiler creates one object file for each source file then stops generating object files. The generated object files follow OS-specific naming conventions.

The following example commands demonstrate how to use `[Q]ipo2` option to compile large programs.

Linux and macOS

```
icpc -ipo2 -c a.cpp b.cpp
```

The resulting object files are `ipo_out.o`, `ipo_out1.o`, and `ipo_out2.o`.

Windows

```
icl /Qipo2 /c a.cpp b.cpp
```

The resulting object files are `ipo_out.obj`, `ipo_out1.obj`, and `ipo_out2.obj`.

Link the resulting object files as shown in Use Interprocedural Optimization or Linking Tools and Options..

Creating the Maximum Number of Object Files

Using `[Q]ipo-separate` allows you to force the compiler to generate the maximum number of true object files that the compiler will support during multiple object compilation. The maximum number of true object files is the equal to the number of mock object files passed on the link line.

For example, you can pass example commands similar to the following:

Linux and macOS

```
icpc -ipo-separate -ipo-c a.o b.o c.o
```

Windows

```
icl /Qipo-separate /Qipo-c a.obj b.obj c.obj
```

The compiler generates multiple object files that use the same naming convention discussed above.

Link the resulting object files as shown in Using IPO or Linking Tools and Options.

Understanding Code Layout and Multi-Object IPO

One of the optimizations performed during an IPO compilation is code layout. The analysis performed by the compiler during multi-file IPO determines a layout order for all of the routines for which it has intermediate representation (IR) information. For a multi-object IPO compilation, the compiler must tell the linker about the desired order.

The compiler first puts each routine in a named text section that varies depending on the operating system:

Linux

The first routine is placed in `.text00001`, the second is placed in `.text00002`, and so on.

Windows

The first routine is placed in `.text$00001`, the second is placed in `.text$00002`, and so on.

Create a Library from IPO Objects

Libraries are often created using a library manager such as `xiar` for Linux/macOS or `xilib` for Windows. Given a list of objects, the library manager will insert the objects into a named library to be used in subsequent link steps.

Linux and macOS

Use `xiar` to create a library from a list of objects. For example the following command creates a library named `user.a` containing the `a.o` and `b.o` objects:

```
xiar cru user.a a.o b.o
```

If the objects have been created using `[Q]ipo -c` then the archive will not only contain a valid object, but the archive will also contain intermediate representation (IR) for that object file. For example, the following example will produce `a.o` and `b.o` that may be archived to produce a library containing both object code and IR for each source file. For example:

```
icc -ipo -c a.cpp b.cpp
```

The commands generate mock object files, which when placed in archive will also be accompanied by a true object file.

Using `xiar` is the same as specifying `xild -lib`.

macOS

When using `xilibtool`, specify `-static` to generate static libraries, or specify `dynamic` to create dynamic libraries. For example, the following command will create a static library named `mylib.a` that includes the `a.o`, `b.o`, and `c.o` objects:

```
xilibtool -static -o mylib.a a.o b.o c.o
```

Alternately, the following example command will create a dynamic library named `mylib.dylib` that includes the `a.o`, `b.o`, and `c.o` objects.

```
xilibtool -dynamic -o mylib.dylib a.o b.o c.o
```

Specifying `xilibtool` is the same as specifying `xild -libtool`.

Windows

Use `xilib` or `xilink -lib` to create libraries of IPO mock object files and link them on the command line.

For example:

1. Assume that you create three mock object files using a command similar to:

```
icl /c /Qipo a.cpp b.cpp c.cpp
```

2. Further assume `a.obj` contains the main subprogram. Create a library with a command similar to:

```
xilib -out:main.lib b.obj c.obj
```

or

```
xilink -lib -out:main.lib b.obj c.obj
```

3. Link the library and the main program object file with a command similar to:

```
xilink -out:result.exe a.obj main.lib
```

Request Compiler Reports with the xi* Tools

The compiler options `qopt-report` (Linux* and macOS) and `[Q]opt-report` (Windows*) generate optimization reports with different levels of detail. Related compiler options, listed under Optimization Report Options, allow you to specify the phase, direct output to a file (instead of `stderr`), and request reports from all routines with names containing a specific string as part of their name.

The xi* tools are used with inter-procedural optimization (IPO) during the final stage of IPO compilation. You can request compiler reports to be generated during the final IPO compilation by using certain options. The supported xi* tools are:

- Linker tools: `xilink` (Windows*) and `xild` (Linux* and macOS)
- Library tools: `xilib` (Windows*), `xiar` (Linux* and macOS), `xilibtool` (macOS)

The following tables lists the compiler report options that can be used with the xi* tools during the final IPO compilation.

Optimization Report Option	Description
`-qopt-report`[=*n*] (Linux* and macOS) `/Qopt-report`[:*n*] (Windows*)	Enables optimization report generation with different levels of detail. Valid values for *n* are 0 through 5. By default, when you specify this option without passing a value the compiler will generate a report with a medium level of detail. Higher numbers give greater levels of detail.
`-qopt-report-file`=*filename* (Linux* and macOS) `/Qopt-report-file`:*filename* (Windows*)	Generates an optimization report and directs the report output to the specified *file* name. If you omit the path, the file is created in the current directory. To create the file in a different directory, specify the full path to the output file and its file name.
`-qopt-report-phase`[=*list*] (Linux* and macOS) `/Qopt-report-phase`[:*list*] (Windows*)	Specifies a comma separated *list* of optimization phases to use when generating reports. If you do not specify a phase the compiler defaults to all. You can request a list of all available phases by using the `[Q]opt-report-help` option. To generate a report for the IPO phase, use the `-qopt-report-phase=`*ipo* (Linux* and macOS) or `/Qopt-report-phase:`*ipo* (Windows) option.

Optimization Report Option	Description
`-qopt-report-routine=`*substring* (Linux* and macOS) `/Qopt-report-routine:`*substring* (Windows*)	Generates reports for all routines with names containing *substring* as part of their name. You can also specify a sequence of substrings separated by commas. If you do this, the compiler generates an optimization report for each of the routines whose name contains one or more of these substrings. If *substring* is not specified, the compiler generates reports on all routines.
`-qopt-report-filter=`*string* (Linux* and macOS) `/Qopt-report-filter:`*string* (Windows*)	Tells the compiler to find the indicated parts of your application specified by *string*, and generate optimization reports for them. If both `-qopt-report-routines=`*string1* and `qopt-report-filter=`*string2* are specified, it is treated as `-qopt-report-filter=`*string1;string2*.
`-qopt-report-help` (Linux* and macOS) `/Qopt-report-help` (Windows*)	Displays the optimization phases available to use when using the `-qopt-report-phase` (Linux* and macOS) or `[q or Q]opt-report-phase` (Windows*) or option.
`-qopt-report-names` (Linux* and macOS) `/Qopt-report-names` (Windows*)	Specifies whether mangled or unmangled names appear in the optimization report. If this option is not specified, unmangled names are used by default. If you specify mangled, encoding (also known as decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the assembly listing. If you specify unmangled, no encoding (or decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the source listing. If you use this option, you do not have to specify option `-qopt-report` (Linux* OS and macOS) or `/Qopt-report` (Windows* OS).

Inline Expansion of Functions

Inline function expansion does not require that the applications meet the criteria for whole program analysis normally required by IPO; so this optimization is one of the most important optimizations done in Interprocedural Optimization (IPO). For function calls that the compiler believes are frequently executed, the compiler often decides to replace the instructions of the call with code for the function itself.

In the compiler, inline function expansion is performed on relatively small user functions more often than on functions that are relatively large. This optimization improves application performance by performing the following:

- Removing the need to set up parameters for a function call
- Eliminating the function call branch
- Propagating constants

Function inlining can improve execution time by removing the runtime overhead of function calls; however, function inlining can increase code size, code complexity, and compile times. In general, when you instruct the compiler to perform function inlining, the compiler can examine the source code in a much larger context, and the compiler can find more opportunities to apply optimizations.

Specifying the `[Q]ip` compiler option, single-file IPO, causes the compiler to perform inline function expansion for calls to procedures defined within the current source file; in contrast, specifying the `[Q]ipo` compiler option, multi-file IPO, causes the compiler to perform inline function expansion for calls to procedures defined in other files.

Caution
Using the `[Q]ip` and `[Q]ipo` (Windows*) options can, in some cases, significantly increase compile time and code size.

The compiler does a certain amount of inlining at the default level. Although such inlining is similar to what is done when you use the [Q]ip option, the amount of inlining done is generally less than when you use the option.

Selecting Routines for Inlining

The compiler attempts to select the routines whose inline expansions provide the greatest benefit to program performance. The selection is done using default heuristics. The inlining heuristics used by the compiler differ based on whether or not you use options for Profile-Guided Optimizations (PGO): `[Q]prof-use` compiler option.

When you use PGO with `[Q]ip` or `[Q]ipo`, the compiler uses the following guidelines for applying heuristics:

- The default heuristic focuses on the most frequently executed call sites, based on the profile information gathered for the program.
- The default heuristic always inlines very small functions that meet the minimum inline criteria.

Using IPO with PGO

Combining IPO and PGO typically produces better results than using IPO alone. PGO produces dynamic profiling information that can usually provide better optimization opportunities than the static profiling information used in IPO.

The compiler uses characteristics of the source code to estimate which function calls are executed most frequently. It applies these estimates to the PGO-based guidelines described above. The estimation of frequency, based on static characteristics of the source, is not always accurate.

Inline Expansion of Library Functions

By default, the compiler automatically inlines (expands) a number of standard and math library functions at the point of the call to that function, which usually results in faster computation.

Many routines in the `libirc`, `libm`, or the `svml` library are more highly optimized for Intel microprocessors than for non-Intel microprocessors.

The `-fno-builtin` (Linux* and macOS) or the `/Qno-builtin-<name>` and `/Oi-` (Windows*) options disable inlining for intrinsic functions and disable the by-name recognition support of intrinsic functions and the resulting optimizations. The `/Qno-builtin-<name>` option provides the ability to disable inlining for intrinsic functions, fine-tuning the functionality of the `/Oi-` option, which disables almost all intrinsic functions when used. Use these options if you redefine standard library routines with your own version and your version of the routine has the same name as the standard library routine.

Inlining and Function Preemption (Linux)

You must specify `fpic` to use function preemption. By default the compiler does not generate the position-independent code needed for preemption.

Compiler Directed Inline Expansion of Functions

Without directions from the user, the compiler attempts to estimate what functions should be inlined to optimize application performance.

The following options are useful in situations where an application can benefit from user function inlining but does not need specific direction about inlining limits.

Option	Effect
`inline-level`(Linux* and macOS) or `Ob` (Windows*)	Specifies the level of inline function expansion. Note that the option /Ob2 on Windows* is equivalent to -inline-level=2 on Linux* and macOS. Allowed values are 0, 1, and 2.
`[Q]ip-no-inlining`	Disables only inlining enabled by the `[Q]ip`, `[Q]ipo`, or `Ob2` options.
`[Q]ip-no-pinlining`	Disables partial inlining enabled by the `[Q]ip` or `[Q]ipo` options. No other IPO optimizations are disabled.
`fno-builtin` (Linux* and macOS) or `Oi-` (Windows)	Disables inlining for intrinsic functions. Disables the by-name recognition support of intrinsic functions and the resulting optimizations. Use this option if you redefine standard library routines with your own version and your version of the routine has the same name as the standard library routine. By default, the compiler automatically inlines (expands) a number of standard and math library functions at the point of the call to that function, which usually results in faster computation. Many routines in the `libirc`, `libm`, or `svml` library are more highly optimized for Intel microprocessors than for non-Intel microprocessors.
setting `inline-debug-info` for the `debug` option	Indicates that the source position information for an inlined function should be retained, rather than replaced, by that of the call which is being inlined.

Developer Directed Inline Expansion of User Functions

In addition to the options that support compiler directed inline expansion of user functions, the compiler also provides compiler options and pragmas that allow you to more precisely direct when and if inline function expansion should occur.

The compiler measures the relative size of a routine in an abstract value of intermediate language units, which is approximately equivalent to the number of instructions that will be generated. The compiler uses the intermediate language unit estimates to classify routines and functions as relatively small, medium, or large functions. The compiler then uses the estimates to determine when to inline a function; if the minimum criteria for inlining is met and all other things are equal, the compiler has an affinity for inlining relatively small functions and not inlining relative large functions.

Typically, the compiler targets functions that have been marked for inlining based on the following:

- **Inlining keywords:** Tells the compiler to inline the specified function. For example, `__inline`, `__forceinline`.
- **Procedure-specific inlining pragmas:** Tells the compiler to inline calls within the targeted procedure if it is legal to do so. For example,`#pragma inline` or `#pragma forceinline` .
- **GCC function attributes for inlining:** Tells the compiler to inline the function even when no optimization level is specified. For example, `__attribute__((always_inline))`.

The following developer directed inlining options and pragmas provide the ability to change the boundaries used by the inliner to distinguish between small and large functions.

In general, you should use the `[Q]inline-factor` option before using the individual inlining options listed below; this single option effectively controls several other upper-limit options.

If your code hits an inlining limit, the compiler issues a warning at the highest warning level. The warning specifies which of the inlining limits have been hit, and the compiler option and/or pragmas needed to get a full report. For example, you could get a message as follows:

```
Inlining inhibited by limit max-total-size.  Use -qopt-report -qopt-report-phase=ipo for full
report.
```

Messages in the report refer directly to the command line options or pragmas that can be used to overcome the limits.

The following table lists the options you can use to fine-tune inline expansion of functions. The pragmas associated with the options are documented in the **Effect** column.

Option	Effect
`[Q]inline-factor`	Controls the multiplier applied to all inlining options that define upper limits: `inline-max-size`, `inline-max-total-size`, `inline-max-per-routine`, and `inline-max-per-compile`. While you can specify an individual increase in any of the upper-limit options, this single option provides an efficient means of controlling all of the upper-limit options with a single command. By default, this option uses a multiplier of 100, which corresponds to a factor of 1. Specifying 200 implies a factor of 2, and so on. Experiment with the multiplier carefully. You could increase the upper limits to allow too much inlining, which might result in your system running out of memory.
`[Q]inline-force-inline`	Instructs the compiler to force inlining of functions suggested for inlining whenever the compiler is capable doing so.

Option	Effect
	Without this option, the compiler treats functions declared with the `__inline` keyword as merely being recommended for inlining. When this option is used, it is as if they were declared with the `__forceinline` keyword.
`[Q]inline-min-size`	Redefines the maximum size of small routines; routines that are equal to or smaller than the value specified are more likely to be inlined.
`[Q]inline-max-size`	Redefines the minimum size of large routines; routines that are equal to or larger than the value specified are less likely to be inlined.
`[Q]inline-max-total-size`	Limits the expanded size of inlined functions. You can also use #pragma optimization_parameter inline-max-total-size=N to control the size an individual routine can grow through inlining.
`[Q]inline-max-per-routine`	Limits the number of times inlining can be applied within a routine. You can also use #pragma optimization_parameter inline-max-per-routine to control the number of times inlining may be applied to a routine.
`[Q]inline-max-per-compile`	Limits the number of times inlining can be applied within a compilation unit. The compilation unit limit depends on the whether or not you specify the `[Q]ipo` compiler option. If you enable IPO, all source files that are part of the compilation are considered one compilation unit. For compilations not involving IPO each source file is considered an individual compilation unit.

Inlining Report

Function inlining can improve execution time by removing the runtime overhead of function calls; however, function inlining can increase code size, code complexity, and compile times. In general, when you instruct the compiler to perform function inlining, the compiler examines the source code in a much larger context, and the compiler can find more opportunities to apply optimizations.

The Inlining Report is part of the Opt Report. The compiler options `-qopt-report` (Linux* and macOS) and `/Qopt-report` (Windows*) generate optimization reports with different levels of detail. Related compiler options, listed under Optimization Report Options, allow you to specify the phase, direct output to a specific file, `stdout` or `stderr`, and request reports from all routines with names containing a specific string as part of their name.

The inlining report is a description of the inlining choices that were made for each routine that is compiled in the program. It is produced as part of the opt report. To restrict the opt report to contain ONLY the inlining report, use the option `-qopt-report-phase=ipo` (Linux* and macOS) or `/Qopt-report-phase:ipo` (Windows*).

The user can control the amount of information by specifying a level for the inlining report. The level is shown by a number from 1 to 5. Level 1 contains the smallest amount of information, and each level adds information to the report. Level 2 is the default report.

Level	**Summary**
Level 1	Shows each call that was inlined
Level 2 (default report)	Shows the values of the key inlining options
Level 3	Shows the calls to routines with external linkage
Level 4	Shows: • Whole program information • Size (sz) of the each routine inlined and the increase in application size (isz) due to each instance of inlining • Routine percentages • Calls that are not inlined
Level 5	Shows inlining footnotes, which contain advice on how to change the inlining to potentially improve application performance

The inlining report gives you an in-depth overview of the compiler's inlining decisions, which occur within five levels of granularity. You can specify levels with `-qopt-report=1`, `-qopt-report=2`, etc., (Linux* and macOS) or `/Qopt-report=1`, `/Qopt-report=2`, etc. (Windows*). See below for specific level details.

Level 1

The Inlining Report is activated when you run the Optimization Report, using `[q or Q]qopt-report`.

For each routine you compile, you get one report with the title INLINE REPORT that shows the calls inlined into that routine.

Example: Inlining Report Level 1 - Typical Routine

```
INLINE REPORT: (APPLU)
  -> INLINE: (295,12) SETBV
    -> INLINE: (398,18) EXACT
    -> INLINE: (399,18) EXACT
    -> INLINE: (409,18) EXACT
    -> INLINE: (410,18) EXACT
```

Example: Inlining Report Level 1 - Typical Routine

```
    -> INLINE: (420,18) EXACT
    -> INLINE: (421,18) EXACT
  -> INLINE: (299,12) SETIV
  -> (303,12) ERHS
  -> (307,12) SSOR
  -> INLINE: (311,12) ERROR
    -> INLINE: (1518,24) EXACT
    -> INLINE: (1552,24) EXACT
  -> INLINE: (315,12) PINTGR
  -> (319,12) VERIFY
```

The report gives the name of the compiled routine (APPLU), and contains one line for each call that the compiler decided to inline or not inline. In the above report, the compiler made 15 inlining decisions for calls in the routine APPLU. It decided to inline 12 of the calls. These decisions are indicated by the lines which start with `-> INLINE`. It decided not to inline three of the calls. These decisions are indicated by the lines without the word INLINE.

On each line, the position of the call in the source code is given in parentheses, followed by the name of the routine being called. For example:

```
-> INLINE: (398,18) EXACT
```

This refers to a call at line 398 column 18 to a routine called EXACT.

Level 2

Level 2 includes the values of important compiler options related to inlining. Unless the user specifies one of these values by using the option on the command line, the default value of the option in shown. You can read more about the meaning of the individual inlining options in the Inlining Options section.

Example: Inlining Report Level 2 - Values of Inlining Options

```
INLINING OPTION VALUES:
  -inline-factor: 100
  -inline-min-size: 30
  -inline-max-size: 230
  -inline-max-total-size: 2000
  -inline-max-per-routine: 10000
  -inline-max-per-compile: 500000
```

Level 3

Level 3 contains one additional line for each call to an external routine made in the application. Such calls are not candidates for inlining, because the code for these routines is not present in the file or files being compiled.

Example: Inlining Report Level 3 - External Linkage

```
Begin optimization report for: APPLU
    Report from: Interprocedural optimizations [ipo]
INLINE REPORT: (APPLU) [1] applu.f (1,16)
   -> EXTERN: (1,16) for_set_reentrancy
   -> EXTERN: (80,7) for_read_seq_lis
```

Level 4

Level 4 adds four additional pieces of information. The specifics are shown below:

- Whole Program values:

Example: Whole Program

```
WHOLE PROGRAM [SAFE] [EITHER METHOD]: false
WHOLE PROGRAM [SEEN] [TABLE METHOD]: true
WHOLE PROGRAM [READ] [OBJECT READER METHOD]: false
```

An application for which whole program is determined is subject to a higher degree of optimization than one which is not. The Intel compiler uses two methods of determining whole program, a TABLE METHOD and an OBJECT READER METHOD.

- The size of the routine [sz] and the inlined size of the routine [isz]. Usually isz is less than sz:

Example: Size of the Routine (sz) vs. Inlined Size of the Routine (isz)

```
 -> INLINE: (295,12) SETBV (isz = 752) (sz = 755)
   -> INLINE: (398,18) EXACT (isz = 98) (sz = 109)
```

In the above example, the routine SETBV was inlined into the routine that called it. The size of SETBV, before inlining, was 755 units. After inlining, the calling routine was increased by 752 units. The increase in the size of the calling routine is slightly less than the size of SETBV, because some of the overhead of calling SETBV was removed when SETBV was inlined.

- The percentage of time that has passed in the process of compiling the file:

Example: Percentage of Time Passed During Compilation

```
INLINE REPORT: (APPLU) [1/16=6.2%] applu.f (1,16)
```

For example, on the line above, [1/16 = 6.2%] indicates that APPLU is the first routine out of 16 to be compiled, and when this routine is done being compiled, 6.2% of the compilation is finished. You can use these numbers to estimate how long the compilation is going to take.

- The calls that did not get inlined and the reason why they did not get inlined. The reason is shown in double brackets [[ ]].

Example: Calls That Are Not Inlined

```
-> (303,12) ERHS (isz = 2125) (sz = 2128)
   [[ Inlining would exceed -inline-max-size value (2128>253)]]
```

In the above example, the routine ERHS is not inlined, because the size of the routine (2128 units) is larger than the allowable size (253 units). If you wish to inline routines that are this large, you can use the option `-inline-max-size=2128` (or larger).

Level 5

Level 5 adds the inlining footnotes.

Example: Use of Footnote

```
-> (303,12) ERHS (isz = 2058) (sz = 2061)
   [[ Inlining would exceed -inline-max-size-value (2061>230) <1>]]
```

The inlining footnotes explain the text found in the double brackets [[ ]]. They include a description for why an inlining call did not happen, and what you can do to make the inlining of this call happen.

The footnote annotation <1> refers to the first footnote in the INLINING FOOTNOTES section at the bottom of the inlining report, which is produced when the user selects Level 5. For example, the footnote produced for annotation <1> above is:

Example: Footnote Text

```
<1> The subprogram is larger than the inliner would normally inline. Use the
option -inline-max-size to increase the size of any subprogram that would
normally be inlined, add “!DIR$ATTRIBUTES FORCELINE” to the
declaration of the called function, or add “!DIR$ FORCELINE” before
the call site.
```

Processor Targeting

The manual processor dispatch feature allows you to target processors manually. You can control processor dispatching in a number of ways, including:

- Use the `cpu_specific` and `cpu_dispatch` keywords (attributes in Linux* or `__declspecs` in Windows*) to write one or more versions of a function that executes only on specified types of Intel® processors. You can also write a generic version that executes on other Intel or non-Intel processors. The Intel processor type is detected at runtime, and the corresponding function version is executed. This feature is available only for Intel processors based on IA-32 or Intel® 64 architecture. The feature not available for non-Intel processors. Applications built using the manual processor dispatch feature may be more highly optimized for Intel processors than for non-Intel processors.

  For more information, see below.
- Use the `optimization_parameter` pragma.

  For more information, see below.
- On Linux, in addition to the Intel-defined attributes `cpu_specific` and `cpu_dispatch`, C++ compilations with GNU Compiler Collection (GCC*) compatibility 4.8 or higher support creation of multiple function versions using the `target` attribute.

  For more information, see the GCC documentation on Function Multiversioning.

Using `cpu_dispatch` for Manual Processor Dispatch Programming

Use the `__declspec(cpu_dispatch(cpuid, cpuid,...))` syntax in your code to provide a list of targeted processors along with an empty function body/function stub. Use the `__declspec(cpu_specific(cpuid))` in your code to declare each function version targeted at particular type[s] of processors.

For a list of the values for `cpuid`, see the list on cpu_dispatch, cpu_specific.

NOTE
If no other matching Intel processor type is detected, the *generic* version of the function is executed. If you want the program to execute on non-Intel processors, a *generic* function version must be provided. You can control the degree of optimization of the *generic* function version and the processor features that it assumes.

The `cpuid` attributes are not case sensitive. The body of a function declared with `__declspec(cpu_dispatch)` must be empty, and is referred to as a stub (an empty-bodied function).

The following example illustrates how the `cpu_dispatch` and `cpu_specific` keywords can be used to create function versions for the 2nd generation Intel® Core™ processor family with support of Intel® Advanced Vector Extensions (Intel® AVX), for the Intel® Core™ processor family, for the Intel® Core™2 Duo processor family, and for other Intel and compatible, non-Intel processors. Each processor-specific function body might contain processor-specific intrinsic functions, or it might be placed in a separate source file and compiled with a processor-specific compiler option.

Example

```
#include <stdio.h>
// need to create specific function versions for the following processors:
__declspec(cpu_dispatch(core_2nd_gen_avx, core_i7_sse4_2, core_2_duo_ssse3, generic ))
void dispatch_func() {};      //  stub that will call the appropriate specific function
version

__declspec(cpu_specific(core_2nd_gen_avx))
void dispatch_func() {
  printf("\nCode for 2nd generation Intel Core processors with support for Intel AVX goes here
\n");
}

__declspec(cpu_specific(core_i7_sse4_2))
void dispatch_func() {
  printf("\nCode for Intel Core processors with support for SSE4.2 goes here\n");
}

__declspec(cpu_specific(core_2_duo_ssse3))
void dispatch_func() {
  printf("\nCode for Intel Core 2 Duo processors with support for SSSE3 goes here\n");
}

__declspec(cpu_specific(generic))
void dispatch_func() {
  printf("\nCode for non-Intel processors and generic Intel processors goes here\n");
}

int main() {
  dispatch_func();
  printf("Return from dispatch_func\n");
  return 0;
}
```

Considerations

Before using manual dispatch, consider whether the benefits outweigh the additional effort and possible performance issues. You may encounter any one or all of the following issues when using manual processor dispatch in your code:

- code and executable sizes increase considerably
- additional performance overhead may be introduced because of additional function calls

Test your application on all targeted platforms before release.

Using Pragmas to Target Processors Manually

You can use `#pragma intel optimization_parameter target_arch` to flag those routines in your code that you want to execute on specified types of processors. This pragma controls the `-m`or `/arch` option at a routine level, overriding the option values specified at the command-line, using the same values as the `-m` or `/arch` option to target processors. The following example illustrates how to use the pragma to target a routine `bar()` to execute only on Intel® AVX supported processors regardless of what the command-line has specified.

Example

```
include <immintrin.h>
#define N 1024

double x[N], y[N], z[N];

#pragma
intel optimization_parameter target_arch=AVX

void bar()
{
    int i;
    if (allow_avx) {
        _allow_cpu_features(_FEATURE_AVX);
        for (i = 0; i < N; i++) {
            z[i] = x[i] * y[i];
        }
    }
    else {
        for (i = 0; i < N; i++) {
            z[i] = x[i] * y[i];
        }
    }
}
```

You can also use the `_allow_cpu_features` intrinsic to tell the compiler that the code region may be targeted for processors with specified features, and the `_may_i_use_cpu_feature` to query the processor dynamically at the source level to determine if processor-specific features are available.

Product and Performance Information

Performance varies by use, configuration and other factors. Learn more at www.Intel.com/PerformanceIndex.

`m`

CPU Feature Targeting

The compiler provides a CPU-dispatching feature that enables users to provide different implementations of their functionality. The CPU-dispatching mechanism checks the target architecture and then selects the best implementation at runtime. However, the mechanism has two related potential limitations:

- Users cannot control the selected code path when they have a particular reason to do so; this can be decided only by the CPU-dispatching mechanism at runtime according to the target platform.
- Users cannot test their different implementations on the same machine.

CPU feature targeting addresses these limitations.

Usage

CPU feature targeting does not add any command-line options. Instead, the user must set a new environment variable, `INTEL_ISA_DISABLE`, before running their application.

The user can set the environment variable as follows (Linux example):

```
export INTEL_ISA_DISABLE=features
```

where *features* is a comma-separated list of features such as `sse2,avx`.

NOTE The feature names are those used with the `-m` option.

Setting the environment variable causes the named features not to be visible on the host even if the `CPUID` reports that it has them onboard. This has the following implications:

- If the user disables a CPU feature (for example, `_FEATURE_SSE2`) using `export INTEL_ISA_DISABLE=sse2`, then `_may_i_use_cpu_feature(_FEATURE_SSE2)` will return false; however, there will be no impact on other features for `_may_i_use_cpu_feature`.
- The CPU-dispatching mechanism will be affected; that is, dispatching will not take paths that require features disabled via `INTEL_ISA_DISABLE`.
- Libraries that use `libirc` for their CPU dispatching (such as `mkl` and `libimf`/`libsvml`) will be affected by `INTEL_ISA_DISABLE` in the same way.

Additional Information

- CPU feature targeting has no architecture restrictions. Users can set the environment variable effectively on all our current architectures.
- CPU feature targeting has no default setting (such as OFF or ON). The feature is triggered by the `INTEL_ISA_DISABLE` environment variable, so if users do not set that variable before running their application, everything works normally (with no CPU feature targeting). Also, if users specify invalid feature names within the environment variable's value, those names will be ignored.
- There is no IDE equivalent for the CPU feature targeting feature.

Important points to remember

- The value of environment variable `INTEL_ISA_DISABLE` is a feature list string comprising feature names separated by commas. The feature names are those used with the `-m` option.
- Users must set `INTEL_ISA_DISABLE` before running their application.
- Users must not disable any feature that is requested by the `-x` *`target`* option. For example, if you compile with `-xcore-avx2` and then disable `fma` (which is required by avx2) via the `INTEL_ISA_DISABLE` environment variable, a runtime error will occur indicating that the CPU is not supported.

Example

`hide_avx.c`:

```
#include "immintrin.h"
#define CHECK(feature) \
printf("%3s: %s\n", _may_i_use_cpu_feature(feature) ? "yes" : "no", #feature);

int main() {
```

```
    CHECK(_FEATURE_GENERIC_IA32);
    CHECK(_FEATURE_SSE4_2);
    CHECK(_FEATURE_AVX);
    CHECK(_FEATURE_AVX2);
    return 0;
}
```

Build `hide_avx.c` using `icc`:

```
icc hide_avx.c -o hide_avx.exe
```

Run `hide_avx.exe` on a machine with avx2, producing the following output:

```
yes: _FEATURE_GENERIC_IA32
yes: _FEATURE_SSE4_2
yes: _FEATURE_AVX
yes: _FEATURE_AVX2
```

Then set the environment variable on the command line:

```
export INTEL_ISA_DISABLE=avx2,avx
```

And then run `hide_avx.exe` again, producing the following output:

```
yes: _FEATURE_GENERIC_IA32
yes: _FEATURE_SSE4_2
no: _FEATURE_AVX
no: _FEATURE_AVX2
```

Methods to Optimize Code Size

This section provides some guidance on how to achieve smaller object and smaller executable size when using the optimizing features of Intel compilers.

There are two compiler options that are designed to prioritize code size over performance:

Option	Result	Notes
`Os`	Favors size over speed	This option enables optimizations that do not increase code size; it produces smaller code size than option `O2`. Option `Os` disables some optimizations that may increase code size for a small speed benefit.
`O1`	Minimizes code size	Compared to option `Os`, option `O1` disables even more optimizations that are generally known to increase code size. Specifying option `O1` implies option `Os`.

Option	Result	Notes
		As an intermediate step in reducing code size, you can replace option `O3` with option `O2` before specifying option `O1`. Option `O1` may improve performance for applications with very large code size, many branches, and execution time not dominated by code within loops.

For more information about compiler options mentioned in this topic, see their full descriptions in the Compiler Reference.

The rest of this topic briefly discusses other methods that may help you further improve code size even when compared to the default behaviors of options `Os` and `O1`.

Things to remember:

- Some of these methods may already be applied by default when options `Os` and `O1` are specified. All the methods mentioned in this topic can be applied at higher optimization levels.
- Some of the options referred to in this topic will not necessarily cause code size reduction, and they may provide varying results (good, bad, or neutral) based on the characteristics of the target code. Still, these are the recommended things to try to see if they cause your binaries to become smaller while maintaining acceptable performance.

Disable or Decrease the Amount of Inlining

Inlining replaces a call to a function with the body of the function. This lets the compiler optimize the code for the inlined function in the context of its caller, usually yielding more specialized and better performing code. This also removes the overhead of calling the function at runtime.

However, replacing a call to a function by the code for that function usually increases code size. The code size increase can be substantial. To eliminate this code size increase, at the cost of the potential performance improvement, inlining can be disabled.

As an alternative to completely disabling inlining, the default amount of inlining can be decreased by using an inline factor less than the default value of 100. It corresponds to scaling the default values of the main inlining parameters by *n*%.

- Advantage: Disabling or reducing this optimization can reduce code size.
- Disadvantage: Performance is likely to be sacrificed by disabling or reducing inlining especially for applications with many small functions.

Use options to disable inlining:

Linux and macOS

`fno-inline`

Windows

`Ob0`

Use options to reduce inlining and factor the main inlining parameters:

Linux and macOS

`inline-factor=`*n*

Windows

`Qinline-factor:`*n*

Use options to fine tune the main inlining parameters:

Linux and macOS

- `inline-factor`
- `inline-max-per-compile`
- `inline-max-per-routine`
- `inline-max-size`
- `inline-max-total-size`
- `inline-min-size`

Windows

- `Qinline-factor`
- `Qinline-max-per-compile`
- `Qinline-max-per-routine`
- `Qinline-max-size`
- `Qinline-max-total-size`
- `Qinline-min-size`

Strip Symbols from Your Binaries

You can specify a compiler option to omit debugging and symbol information from the executable without sacrificing its operability.

- Advantage: This method noticeably reduces the size of the binary.
- Disadvantage: It may be very difficult to debug a stripped application.

Use options:

Linux

`Wl,--strip-all`

Windows

None

Dynamically Link Intel-provided Libraries

By default, some of the Intel support and performance libraries are linked statically into an executable. As a result, the library codes are linked into every executable being built. This means that codes are duplicated.

It may be more profitable to link them dynamically.

- Advantage: Performance of the resulting executable is normally not significantly affected. Library codes that are otherwise linked in statically into every executable will not contribute to the code size of each executable with this option. These codes will be shared between all executables using them, and they will be available independent of those executables.
- Disadvantage: The libraries on which the resulting executable depends must be re-distributed with the executable for it to work properly. When libraries are linked statically, only library content that is actually used is linked into the executable. Dynamic libraries contain all the library content. Therefore, it may not be beneficial to use this option if you only need to build and/or distribute a single executable. The executable itself may be much smaller when linked dynamically, compared to a statically linked executable. However, the total size of the executable plus shared libraries or DLLs may be much larger than the size of the statically linked executable.

Use Options:

Linux and macOS

`shared-intel`

Windows

```
MD
```

NOTE Option MD affects all libraries, not only the Intel-provided ones.

Exclude Unused Code and Data from the Executable

Programs often contain dead code or data that is not used during their execution. Even if no expensive whole-program inter-procedural analysis is made at compile time to identify dead code, there are compiler options you can specify to eliminate unused functions and data at link time.

This method is often referred to as function-level or data-level linking.

- Advantage: Only the code that is referenced remains in an executable. Dead functions and data are stripped from the executable. For the options passed to the linker, they also enable the linker to reorder the sections for other possible optimization.
- Disadvantage: The object codes may become slightly larger because each function or datum is put into a separate section. The overhead is eliminated at the linking stage. This method requires linker support to strip unused sections and may increase linking time.

Use Options:

Linux and macOS

```
-fdata-sections -ffunction-sections -Wl,--gc-sections
```

Windows

```
/Gw /Gy /link /OPT:REF
```

NOTE Option MD affects all libraries, not only the Intel-provided ones.

These options (from the use options example above) are passed to the linker:

Linux and macOS

```
Wl,--gc-sections
```

Windows

```
link /OPT:REF
```

Disable Recognition and Expansion of Intrinsic Functions

When recognized, intrinsic functions can get expanded inline or their faster implementation in a library may be assumed and linked in. By default, Inline expansion of intrinsic functions is enabled.

In some cases, disabling this behavior may noticeably improve the size of the produced object or binary.

- Advantage: Both the size of the object files and the size of library codes brought into an executable can be reduced.
- Disadvantage: This method can prevent various performance optimizations from happening. Slower standard library implementation will be used. The size of the final executable can be increased in cases when code pulled in statically from a library for an otherwise inlined intrinsic is large.

Use Options:

Linux and macOS

```
fno-builtin
```

Windows

`Oi-`

Additional information:

- This option is already the default if you specify option `O1`.
- For C++, you can specify Linux option `nolib-inline` to disable inline expansion of standard library or intrinsic functions.
- Depending on code characteristics, this option can sometimes increase binary size.

Optimize Exception Handling Data

If a program requires support for exception handling, the compiler creates a special section containing DWARF directives that are used by the Linux and macOSruntime to unwind and catch an exception.

This information is found in the `.eh_frame` section and may be shrunk using the compiler options listed below.

- Advantage:

  These options may shrink the size of the object or binary file by up to 15%, though the amount of the reduction depends on the target platform. These options control whether unwind information is precise at an instruction boundary or at a call boundary. For example, option `fno-asynchronous-unwind-tables` can be used for programs that may *only* throw or catch exceptions.
- Disadvantage: Both options may change the program's behavior. Do not use option `fno-exceptions` for programs that require standard C++ handling for objects of classes with destructors. Do not use option `fno-asynchronous-unwind-tables` for functions compiled with option `-fexceptions` or option `traceback` that contain calls to other functions that might throw exceptions or for C++ functions that declare objects with destructors.

Use Options:

Linux and macOS

`fno-exceptions` or `fno-asynchronous-unwind-tables`

Windows

None

Read the compiler option descriptions, which explain what the defaults and behavior are for each target platform.

Disable Passing Arguments in Registers Instead of on the Stack

You can specify an option that causes the compiler to pass arguments in registers rather than on the stack. This can yield faster code.

However, doing this may require the compiler to create an additional entry point for any function that can be called outside the code being compiled.

In many cases, this will lead to an increase in code size. To prevent this increase in code size, you can disable this optimization.

- Advantage: Disabling this optimization can reduce code size.
- Disadvantage: The amount of code size saved may be small when compared to the corresponding performance loss of disabling the optimization.

Use Options:

Linux and macOS

`qopt-args-in-regs=none`

Windows

`Qopt-args-in-regs:none`

Additional information:

- Specify **none** for option `[q or Q]opt-args-in-regs`. The default behavior for the option is that parameters are passed in registers when they are passed to routines whose definition is seen in the same compilation unit.
- Depending on code characteristics, this option can sometimes increase binary size.

Disable Loop Unrolling

Unrolling a loop increases the size of the loop proportionally to the unroll factor.

Disabling (or limiting) this optimization may help reduce code size at the expense of performance.

- Advantage: Code size is reduced.
- Disadvantage: Performance of otherwise unrolled loops may noticeably degrade because this limits other possible loop optimizations.

Use Options:

Linux and macOS

`unroll=0`

Windows

`Qunroll:0`

Additional information:

This option is already the default if you specify option `Os` or option `O1`.

Disable Automatic Vectorization

The compiler finds possibilities to use SIMD (Intel® Streaming SIMD Extensions (Intel® SSE)/Intel® Advanced Vector Extensions (Intel® AVX)) instructions to improve performance of applications. This optimization is called automatic vectorization.

In most cases, this optimization involves transformation of loops and increases code size, in some cases significantly.

Disabling this optimization may help reduce code size at the expense of performance.

- Advantage: Compile-time is also improved significantly.
- Disadvantage: Performance of otherwise vectorized loops may suffer significantly. If you care about the performance of your application, you should use this option selectively to suppress vectorization on everything except performance-critical parts.

Use Options:

Linux and macOS

`no-vec`

Windows

`Qvec-`

Additional information:

Depending on code characteristics, this option can sometimes increase binary size.

Avoid References to Compiler-specific Libraries

While compiler-specific libraries are intended to improve the performance of your application, they increase the size of your binaries.

Certain compiler options may improve the code size.

- Advantage: The compiler will not assume the presence of compiler-specific libraries. It will generate only calls that appear in the source code.
- Disadvantage: This method may sacrifice performance if the library codes were in hotspots. Also, because we cannot assume any libraries, some compiler optimizations will be suppressed.

Use Options:

Linux and macOS

`ffreestanding`

Windows

`Qfreestanding-`

Additional information:

- This option implies option `fno-builtin`. You can override that default by explicitly specifying option `fbuiltin`.
- Depending on code characteristics, this option can sometimes increase binary size.

Avoid Unnecessary 16-Byte Alignment

This topic only applies to Linux systems on IA-32 architecture.

This method should only be used in certain situations that are well understood. It can potentially cause correctness issues when linking with other objects or libraries that aren't built with this option.

The 32-bit Linux ABI states that stacks need only maintain 4-byte alignment. However, for performance reasons in modern architectures, GCC and ICC maintain an alignment of 16-bytes on the stack. Maintaining 16-byte alignment may require additional instructions to adjust the stack on function entries where no stack adjustment would otherwise be needed. This can impact code size, especially in code that consists of many small routines.

You can specify a compiler option that will revert ICC back to maintaining 4-byte alignment, which can eliminate the need for extra stack adjust instructions in some cases.

Use this option *only* if one of the following is true:

- Your code does not call any other object or library that can be built without this option and, therefore, may rely on the stack being aligned to 16-bytes when called.
- Your code is targeted for architectures that do not have or support SSE instructions; therefore, it would never need 16-byte alignment for correctness reasons.

- Advantage: Code size can be smaller because you do not need extra instructions to maintain 16-byte alignment when not needed. This method can improve performance in some cases because of this reduction of instructions.
- Disadvantage: This method can cause incompatibility when linked with other objects or libraries that rely on the stack being 16-byte aligned across the calls.

Use Options:

Linux

`falign-stack=assume-4-byte`

macOS

None

Windows

None

Additional information:

Depending on code characteristics, this option can sometimes increase binary size.

Use Interprocedural Optimization

Using interprocedural optimization (IPO) may reduce code size. It enables dead code elimination and suppresses generation of code for functions that are always inlined or proven that they are never to be called during execution.

- Advantage: Depending on the code characteristics, this optimization can reduce executable size and improve performance.
- Disadvantage: Binary size can increase depending on code/application..

Use Options:

Linux and macOS

`ipo`

Windows

`Qipo`

> **NOTE** This method is not recommended if you plan to ship object files as part of a final product.

Intel® C++ Compiler Classic Math Library

The Intel® C++ Compiler Classic includes a mathematical software library containing highly optimized and very accurate mathematical functions. These functions are commonly used in scientific or graphic applications, as well as other programs that rely heavily on floating-point computations. To include support for C99 `_Complex` data types, use the `[Q]std=c99` compiler option.

Many routines in the Intel® C++ Compiler Classic Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The `mathimf.h` header file includes prototypes for Intel® C++ Compiler Classic Math Library functions.

> **NOTE**
> Intel's `math.h` header file is compatible with the GCC Math Library `libm`, but it does not cause the GCC Math Library to be linked. The source can be built with `gcc`, `icc`, or `icl`. The header file for the math library, `mathimf.h`, contains additional functions that are found only in the math library. The source can only be built using the compiler and libraries.
>
> The long double functions, such as `expl` or `logl`, in the math library are ABI incompatible with the Microsoft libraries. The Intel compiler and libraries support the 80-bit long double data type (see the description of the Qlong-double option). For maximum compatibility, use `math.h` or `mathimf.h` header files along with the math library.

Compiler Math Libraries for Linux and macOS

The math library linked to an application depends on the compilation or linkage options specified.

Library	**Description**
`libimf.a`	Default static math library.

Library	Description
`libimf.so`	Default shared math library.

NOTE The math libraries contain performance-optimized implementations for various Intel platforms. By default, the best implementation for the underlying hardware is selected at runtime. The library dispatch of multi-threaded code may lead to apparent data races, which may be detected by certain software analysis tools. However, as long as the threads are running on cores with the same CPUID, these data races are harmless and not a cause for concern.

Compiler Math Libraries for Windows

The math library linked to an application depends on the compilation or linkage options specified.

Library	Option	Description
`libm.lib`		Default static math library.
`libmmt.lib`	`/MT`	Multi-threaded static math library.
`libmmd.lib`	`/MD`	Dynamically linked math library.
`libmmdd.lib`	`/MDd`	Dynamically linked debug math library.

oneAPI and OpenCL™ Considerations

Currently, oneAPI uses the OpenCL Specification to determine the ULP accuracy for OpenCL mathematical functions. Details about their precision and accuracy, including tables for single and double precision functions, are available from the Khronos OpenCL Specification's section, Relative Error as ULPs.

Mathematical functions have different accuracy levels on different devices. The OpenCL specification sets a limit on the maximum ULP error (where applicable), but individual devices may provide a more accurate implementation. If the OpenCL implementation is optimized for CPU usage, using the same code may not work on a GPU device.

Use the Intel® C++ Compiler Classic Math Library

Many routines in the Intel® C++ Compiler Classic Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The `mathimf.h` header file includes prototypes for Intel® C++ Compiler Classic Math Library functions.

To use the Intel® C++ Compiler Classic math library, include the header file, `mathimf.h`, in your program. If the compiler is used for linking, then the math library is used by default.

Use Real Functions

The following examples demonstrate how to use the math library with the compiler. After you compile this example and run the program, the program will display the sine value of `x`.

Linux and macOS

```
// real_math.c
#include <stdio.h>
#include <mathimf.h>

int main() {
 float fp32bits;
 double fp64bits;
 long double fp80bits;
 long double pi_by_four = 3.141592653589793238/4.0;

// pi/4 radians is about 45 degrees
 fp32bits = (float) pi_by_four; // float approximation to pi/4
 fp64bits = (double) pi_by_four; // double approximation to pi/4
 fp80bits = pi_by_four; // long double (extended) approximation to pi/4

// The sin(pi/4) is known to be 1/sqrt(2) or approximately .7071067
 printf("When x = %8.8f, sinf(x) = %8.8f \n", fp32bits, sinf(fp32bits));
 printf("When x = %16.16f, sin(x) = %16.16f \n", fp64bits, sin(fp64bits));
 printf("When x = %20.20Lf, sinl(x) = %20.20Lf \n", fp80bits, sinl(fp80bits));

 return 0;
}
```

Use the following command to compile the example code on Linux platforms:

```
icc real_math.c
```

Windows

```
// real_math.c
#include <stdio.h>
#include <mathimf.h>

int main() {
  float fp32bits;
  double fp64bits;

// /Qlong-double compiler option required because, without it,
// long double types are mapped to doubles.
  long double fp80bits;
  long double pi_by_four = 3.141592653589793238/4.0;

// pi/4 radians is about 45 degrees
  fp32bits = (float) pi_by_four;

// float approximation to pi/4
  fp64bits = (double) pi_by_four;

// double approximation to pi/4
  fp80bits = pi_by_four;

// long double (extended) approximation to pi/4
// The sin(pi/4) is known to be 1/sqrt(2) or approximately .7071067
  printf("When x = %8.8f, sinf(x) = %8.8f \n",
```

```
  fp32bits, sinf(fp32bits));

  printf("When x = %16.16f, sin(x) = %16.16f \n",
  fp64bits, sin(fp64bits));

  printf("When x = %20.20f, sinl(x) = %20.20f \n",
  (double) fp80bits, (double) sinl(fp80bits));

// printf() does not support the printing of long doubles
// on Microsoft Windows, so fp80bits is cast to double in this example.
  return 0;
}
```

Since the `real_math.c` program includes the `long double` data type, use the `/Qlong-double` and `/Qpc80` compiler options in the command line:

Use the following command to compile the example code on Windows platforms:

```
icl /Qlong-double /Qpc80 real_math.c
```

Use Complex Functions

After you compile this example and run the program, you should get the following results:

`When z = 1.0000000 + 0.7853982 i, cexpf(z) = 1.9221154 + 1.9221156 i`

`When z = 1.000000000000 + 0.785398163397 i, cexp(z) = 1.922115514080 + 1.922115514080 i`

Linux, macOS, and Windows

```
// complex_math.c
#include <stdio.h>
#include <complex.h>

int main() {
  float _Complex c32in,c32out;
  double _Complex c64in,c64out;
  double pi_by_four= 3.141592653589793238/4.0;
  c64in = 1.0 + I pi_by_four;

// Create the double precision complex number 1 + (pi/4)  i
// where I is the imaginary unit.
  c32in = (float _Complex) c64in;

// Create the float complex value from the double complex value.
  c64out = cexp(c64in);
  c32out = cexpf(c32in);

// Call the complex exponential,
// cexp(z) = cexp(x+iy) = e^ (x + i y) = e^x  (cos(y) + i sin(y))
 printf("When z = %7.7f + %7.7f i, cexpf(z) = %7.7f + %7.7f i \n"
 ,crealf(c32in),cimagf(c32in),crealf(c32out),cimagf(c32out));
 printf("When z = %12.12f + %12.12f i, cexp(z) = %12.12f + %12.12f i \n"
 ,creal(c64in),cimag(c64in),creal(c64out),cimagf(c64out));

  return 0;
}
```

Since this example program includes the `_Complex` data type, be sure to include the `[Q]std=c99` compiler option in the command line. For example:

Linux or macOS

```
icc -std=c99 complex_math.c
```

Windows

```
icl Qstd=c99 complex_math.c
```

NOTE `_Complex` data types are supported in C but not in C++ programs.

Exception Conditions

If you call a math function using argument(s) that may produce undefined results, an error number is assigned to the system variable `errno`. Math function errors are usually domain errors or range errors.

Domain errors result from arguments that are outside the domain of the function. For example, `acos` is defined only for arguments between -1 and +1 inclusive. Attempting to evaluate `acos(-2)` or `acos(3)` results in a domain error, where the return value is `QNaN`.

Range errors occur when a mathematically valid argument results in a function value that exceeds the range of representable values for the floating-point data type. Attempting to evaluate `exp(1000)` results in a range error, where the return value is `INF`.

When domain or range error occurs, the following values are assigned to `errno`:

- domain error (`EDOM`): `errno = 33`
- range error (`ERANGE`): `errno = 34`

The following example shows how to read the `errno` value for an `EDOM` and `ERANGE` error.

```
// errno.c
#include <errno.h>
#include <mathimf.h>
#include <stdio.h>

int main(void) {
  double neg_one=-1.0;
  double zero=0.0;

// The natural log of a negative number is considered a domain error - EDOM
  printf("log(%e) = %e and errno(EDOM) = %d \n",neg_one,log(neg_one),errno);

// The natural log of zero is considered a range error - ERANGE
  printf("log(%e) = %e and errno(ERANGE) = %d \n",zero,log(zero),errno);
}
```

The output of `errno.c` will look like this:

`log(-1.000000e+00) = nan and errno(EDOM) = 33`

`log(0.000000e+00) = -inf and errno(ERANGE) = 34`

For the math functions in this section, a corresponding value for `errno` is listed when applicable.

Other Considerations

Some math functions are inlined automatically by the compiler. The functions actually inlined may vary and may depend on any vectorization or processor-specific compilation options used. You can disable automatic inline expansion of all functions by compiling your program with the `-fno-builtin` option (Linux and macOS) or the `/Oi-` option (Windows).

It is strongly recommended to use the default rounding mode (round-to-nearest-even) when calling math library transcendental functions and compiling with default optimization or higher. Faster implementations—in terms of latency and/or throughput— of these functions are validated under the default round-to-nearest-even mode. Using other rounding modes may make results generated by these faster implementations less accurate, or set unexpected floating-point status flags. This behavior may be avoided by using the `-no-fast-transcendentals` option (Linux and macOS) or `/Qfast-transcendentals-` option (Windows), which disables calls to the faster implementations of math functions, or by using the `-fp-model strict` option (Linux and macOS) or `/fp: strict` option (Windows). This option warns the compiler not to assume default settings for the floating-point environment.

> **NOTE** 64-bit decimal transcendental functions rely on binary double extended precision arithmetic. To obtain accurate results, user applications that call 64-bit decimal transcendentals should ensure that the x87 unit is operating in 80-bit precision (64-bit binary significands). In an environment where the default x87 precision is not 80 bits, such as Windows, it can be set to 80 bits by compiling the application source files with the `/Qpc80` option.

A change of the default precision control or rounding mode may affect the results returned by some of the mathematical functions.

The following are important compiler options when using certain data types in IA-32 and Intel® 64 architectures running Windows operating systems:

- `/Qlong-double`: Use this option when compiling programs that require support for the `long double` data type (80-bit floating-point). Without this option, compilation will be successful, but `long double` data types will be mapped to `double` data types.
- `/Qstd=c99`: Use this option when compiling programs that require support for `_Complex` data types.

Trigonometric Functions

Many routines in the Intel® C++ Compiler Classic Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The `mathimf.h` header file includes prototypes for Intel® C++ Compiler Classic Math Library functions.

The math library supports the following trigonometric functions:

acos

Description: The `acos` function returns the principal value of the inverse cosine of `x` in the range [0, pi] radians for `x` in the interval [-1,1].

errno: EDOM, for |x| > 1

Calling interface:

```
double acos(double x);
long double acosl(long double x);
float acosf(float x);
```

acosd

Description: The `acosd` function returns the principal value of the inverse cosine of `x` in the range [0,180] degrees for `x` in the interval [-1,1].

errno: EDOM, for |x| > 1

Calling interface:

```
double acosd(double x);
long double acosdl(long double x);
float acosdf(float x);
```

acospi

Description: The `acospi` function returns the principal value of the inverse cosine of `x`, divided by pi, in the range [0,1] for `x` in the interval [-1,1].

errno: EDOM, for |x| > 1

Calling interface:
```
double acospi(double x);
float acospif(float x);
```

asin

Description: The `asin` function returns the principal value of the inverse sine of `x` in the range [-pi/2, +pi/2] radians for `x` in the interval [-1,1].

errno: EDOM, for |x| > 1

Calling interface:
```
double asin(double x);
long double asinl(long double x);
float asinf(float x);
```

asind

Description: The `asind` function returns the principal value of the inverse sine of `x` in the range [-90,90] degrees for `x` in the interval [-1,1].

errno: EDOM, for |x| > 1

Calling interface:
```
double asind(double x);
long double asindl(long double x);
float asindf(float x);
```

asinpi

Description: The `asinpi` function returns the principal value of the inverse sine of `x`, divided by pi, in the range [-1/2,1/2] degrees for `x` in the interval [-1,1].

errno: EDOM, for |x| > 1 divided by pi

Calling interface:
```
double asinpi(double x);
float asinpif(float x);
```

atan

Description: The `atan` function returns the principal value of the inverse tangent of `x` in the range [-pi/2, +pi/2] radians.

Calling interface:
```
double atan(double x);
long double atanl(long double x);
float atanf(float x);
```

atan2

Description: The `atan2` function returns the principal value of the inverse tangent of `y/x` in the range [-pi, +pi] radians.

errno: EDOM, for x = 0 and y = 0

Calling interface:
```
double atan2(double y, double x);
long double atan2l(long double y, long double x);
float atan2f(float y, float x);
```

atan2pi

Description: The `atan2pi` function returns the principal value of the inverse tangent of `y/x`, divided by pi, in the range [-1, +1].

errno: EDOM, for x = 0 and y = 0

Calling interface:

```
double atan2pi(double y, double x);
float atan2pif(float y, float x);
```

atand

Description: The `atand` function returns the principal value of the inverse tangent of `x` in the range [-90,90] degrees.

Calling interface:

```
double atand(double x);
long double atandl(long double x);
float atandf(float x);
```

atan2d

Description: The `atan2d` function returns the principal value of the inverse tangent of `y/x` in the range [-180, +180] degrees.

errno: EDOM, for x = 0 and y = 0.

Calling interface:

```
double atan2d(double x, double y);
long double atan2dl(long double x, long double y);
float atan2df(float x, float y);
```

atand2

Description: The `atand2` function returns the principal value of the inverse tangent of `y/x` in the range [-180, +180] degrees.

errno: EDOM, for x = 0 and y = 0.

Calling interface:

```
double atand2(double x, double y);
long double atand2l(long double x, long double y);
float atand2f(float x, float y);
```

atanpi

Description: The `atanpi` function returns the principal value of the inverse tangent of `x`, divided by pi, in the range [-1/2, +1/2].

Calling interface:

```
double atanpi(double x);
float atanpif(float x);
```

cos

Description: The `cos` function returns the cosine of `x` measured in radians.

Calling interface:

```
double cos(double x);
long double cosl(long double x);
```

```
float cosf(float x);
```

cosd

Description: The `cosd` function returns the cosine of `x` measured in degrees.

Calling interface:

```
double cosd(double x);
long double cosdl(long double x);
float cosdf(float x);
```

cospi

Description: The `cospi` function returns the cosine of `x` multiplied by pi, `cos(x*pi)`.

Calling interface:

```
double cospi(double x);
float cospif(float x);
```

cot

Description: The `cot` function returns the cotangent of `x` measured in radians.

errno: ERANGE, for overflow conditions at x = 0.

Calling interface:

```
double cot(double x);
long double cotl(long double x);
float cotf(float x);
```

cotd

Description: The `cotd` function returns the cotangent of `x` measured in degrees.

errno: ERANGE, for overflow conditions at x = 0.

Calling interface:

```
double cotd(double x);
long double cotdl(long double x);
float cotdf(float x);
```

sin

Description: The `sin` function returns the sine of `x` measured in radians.

Calling interface:

```
double sin(double x);
long double sinl(long double x);
float sinf(float x);
```

sincos

Description: The `sincos` function returns both the sine and cosine of `x` measured in radians.

Calling interface:

```
void sincos(double x, double *sinval, double *cosval);
void sincosl(long double x, long double *sinval, long double *cosval);
void sincosf(float x, float *sinval, float *cosval);
```

sincosd

Description: The `sincosd` function returns both the sine and cosine of `x` measured in degrees.

Calling interface:
```
void sincosd(double x, double *sinval, double *cosval);
void sincosdl(long double x, long double *sinval, long double *cosval);
void sincosdf(float x, float *sinval, float *cosval);
```

sind

Description: The `sind` function computes the sine of `x` measured in degrees.

Calling interface:
```
double sind(double x);
long double sindl(long double x);
float sindf(float x);
```

sinpi

Description: The `sinpi` function returns the sine of `x` multiplied by pi, `sin(x*pi)`.

Calling interface:
```
double sinpi(double x);
float sinpif(float x);
```

tan

Description: The `tan` function returns the tangent of `x` measured in radians.

Calling interface:
```
double tan(double x);
long double tanl(long double x);
float tanf(float x);
```

tand

Description: The `tand` function returns the tangent of `x` measured in degrees.

errno: ERANGE, for overflow conditions

Calling interface:
```
double tand(double x);
long double tandl(long double x);
float tandf(float x);
```

tanpi

Description: The `tanpi` function returns the tangent of `x` multiplied by pi, `tan(x*pi)`.

Calling interface:
```
double tanpi(double x);
float tanpif(float x);
```

Hyperbolic Functions

Many routines in the Intel® C++ Compiler Classic Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The `mathimf.h` header file includes prototypes for Intel® C++ Compiler Classic Math Library functions.

The math library supports the following `hyperbolic` functions:

acosh

Description: The `acosh` function returns the inverse hyperbolic cosine of `x`.

errno: EDOM, for x < 1

Calling interface:
```
double acosh(double x);
long double acoshl(long double x);
float acoshf(float x);
```

asinh

Description: The `asinh` function returns the inverse hyperbolic sine of `x`.

Calling interface:
```
double asinh(double x);
long double asinhl(long double x);
float asinhf(float x);
```

atanh

Description: The `atanh` function returns the inverse hyperbolic tangent of `x`.

errno:

EDOM, for |x| > 1

ERANGE, for x = 1

Calling interface:
```
double atanh(double x);
long double atanhl(long double x);
float atanhf(float x);
```

cosh

Description: The `cosh` function returns the hyperbolic cosine of `x`, $(e^{x} + e^{-x})/2$.

errno: ERANGE, for overflow conditions

Calling interface:
```
double cosh(double x);
long double coshl(long double x);
float coshf(float x);
```

sinh

Description: The `sinh` function returns the hyperbolic sine of `x`, $(e^{x} - e^{-x})/2$.

errno: ERANGE, for overflow conditions

Calling interface:
```
double sinh(double x);
long double sinhl(long double x);
float sinhf(float x);
```

sinhcosh

Description: The `sinhcosh` function returns both the hyperbolic sine and hyperbolic cosine of `x`.

errno: ERANGE, for overflow conditions

Calling interface:
```
void sinhcosh(double x, double *sinval, double *cosval);
void sinhcoshl(long double x, long double *sinval, long double *cosval);
void sinhcoshf(float x, float *sinval, float *cosval);
```

tanh

Description: The `tanh` function returns the hyperbolic tangent of `x`, $(e^x - e^{-x}) / (e^x + e^{-x})$.

Calling interface:
```
double tanh(double x);
long double tanhl(long double x);
float tanhf(float x);
```

Exponential Functions

Many routines in the Intel® C++ Compiler Classic Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The `mathimf.h` header file includes prototypes for Intel® C++ Compiler Classic Math Library functions.

The math library supports the following exponential functions:

cbrt

Description: The `cbrt` function returns the cube root of `x`.

Calling interface:
```
double cbrt(double x);
long double cbrtl(long double x);
float cbrtf(float x);
```

exp

Description: The `exp` function returns `e` raised to the `x` power, e^x.

errno: ERANGE, for underflow and overflow conditions

Calling interface:
```
double exp(double x);
long double expl(long double x);
float expf(float x);
```

exp10

Description: The `exp10` function returns 10 raised to the `x` power, 10^x.

errno: ERANGE, for underflow and overflow conditions

Calling interface:
```
double exp10(double x);
long double exp10l(long double x);
float exp10f(float x);
```

exp2

Description: The `exp2` function returns 2 raised to the `x` power, 2^x.

errno: ERANGE, for underflow and overflow conditions

Calling interface:
```
double exp2(double x);
long double exp2l(long double x);
float exp2f(float x);
```

expm1

Description: The `expm1` function returns `e` raised to the `x` power, minus 1, $e^x - 1$.

errno: ERANGE, for overflow conditions

Calling interface:
```
double expm1(double x);
long double expm1l(long double x);
float expm1f(float x);
```

frexp

Description: The `frexp` function converts a floating-point number `x` into signed normalized fraction in [1/2, 1) multiplied by an integral power of two. The signed normalized fraction is returned, and the integer exponent stored at location `exp`.

Calling interface:
```
double frexp(double x, int *exp);
long double frexpl(long double x, int *exp);
float frexpf(float x, int *exp);
```

hypot

Description: The `hypot` function returns the square root of $(x^2 + y^2)$.

errno: ERANGE, for overflow conditions

Calling interface:
```
double hypot(double x, double y);
long double hypotl(long double x, long double y);
float hypotf(float x, float y);
```

ilogb

Description: The `ilogb` function returns the exponent of `x` base two as a `signed int` value.

errno: ERANGE, for x = 0

Calling interface:
```
int ilogb(double x);
int ilogbl(long double x);
int ilogbf(float x);
```

invsqrt

Description: The `invsqrt` function returns the inverse square root.

Calling interface:
```
double invsqrt(double x);
long double invsqrtl(long double x);
float invsqrtf(float x);
```

ldexp

Description: The `ldexp` function returns $x*2^{exp}$, where `exp` is an integer value.

errno: ERANGE, for underflow and overflow conditions

Calling interface:

```
double ldexp(double x, int exp);
long double ldexpl(long double x, int exp);
float ldexpf(float x, int exp);
```

log

Description: The `log` function returns the natural log of `x`, ln(`x`).

errno: EDOM, for x < 0
errno: ERANGE, for x = 0

Calling interface:

```
double log(double x);
long double logl(long double x);
float logf(float x);
```

log10

Description: The `log10` function returns the base-10 log of `x`, $\log_{10}(x)$.

errno: EDOM, for x < 0
errno: ERANGE, for x = 0

Calling interface:

```
double log10(double x);
long double log10l(long double x);
float log10f(float x);
```

log1p

Description: The `log1p` function returns the natural log of `(x+1), ln(x + 1).`

errno: EDOM, for x < -1
errno: ERANGE, for x = -1

Calling interface:

```
double log1p(double x);
long double log1pl(long double x);
float log1pf(float x);
```

log2

Description: The `log2` function returns the base-2 log of `x`, $\log_2(x)$.

errno: EDOM, for x < 0
errno: ERANGE, for x = 0

Calling interface:

```
double log2(double x);
long double log2l(long double x);
float log2f(float x);
```

logb

Description: The `logb` function returns the signed exponent of `x`.

errno: EDOM, for x = 0

Calling interface:

```
double logb(double x);
long double logbl(long double x);
float logbf(float x);
```

pow

Description: The `pow` function returns `x` raised to the power of `y`, x^y.

errno: EDOM, for x = 0 and y < 0
errno: EDOM, for x < 0 and y is a non-integer
errno: ERANGE, for overflow and underflow conditions

Calling interface:

```
double pow(double x, double y);
long double powl(double x, double y);
float powf(float x, float y);
```

pow2o3

Description: The `pow2o3` function returns the cube root of `x` squared, `cbrt(`x^2`)`.

Calling interface:

```
double pow2o3(double x);
float pow2o3f(float x);
```

pow3o2

Description: The `pow3o2` function returns the square root of the cube of `x`, `sqrt(`x^3`)`.

errno: EDOM, for x < 0
errno: ERANGE, for overflow and underflow conditions

Calling interface:

```
double pow3o2(double x);
float pow3o2f(float x);
```

powr

Description: The `powr` function returns `x` raised to the power of `y`, x^y, where x ≥ 0.

errno: EDOM, for x < 0
errno: ERANGE, for overflow and underflow conditions

Calling interface:

```
double powr(double x, double y);
float powrf(float x, float y);
```

scalb

Description: The `scalb` function returns $x*2^y$, where `y` is a floating-point value.

errno: ERANGE, for underflow and overflow conditions

Calling interface:

```
double scalb(double x, double y);
```

```
long double scalbl(long double x, long double y);
float scalbf(float x, float y);
```

scalbn

Description: The `scalbn` function returns $x*2^n$, where `n` is an integer value.

errno: ERANGE, for underflow and overflow conditions

Calling interface:

```
double scalbn(double x, int n);
long double scalbnl (long double x, int n);
float scalbnf(float x, int n);
```

scalbln

Description: The `scalbln` function returns $x*2^n$, where `n` is a long integer value.

errno: ERANGE, for underflow and overflow conditions

Calling interface:

```
double scalbln(double x, long int n);
long double scalblnl (long double x, long int n);
float scalblnf(float x, long int n);
```

sqrt

Description: The `sqrt` function returns the correctly rounded square root.

errno: EDOM, for $x < 0$

Calling interface:

```
double sqrt(double x);
long double sqrtl(long double x);
float sqrtf(float x);
```

Special Functions

Many routines in the Intel® C++ Compiler Classic Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The `mathimf.h` header file includes prototypes for Intel® C++ Compiler Classic Math Library functions.

The math library supports the following special functions:

annuity

Description: The `annuity` function computes the present value factor for an annuity, $(1 - (1+x)^{(-y)}) / x$, where `x` is a rate and `y` is a period.

errno: ERANGE, for underflow and overflow conditions

Calling interface:

```
double annuity(double x, double y);
long double annuityl(long double x, long double y);
float annuityf(float x, float y);
```

cdfnorm

Description: The `cdfnorm` function returns the cumulative normal distribution function value.

Calling interface:
```
double cdfnorm(double x);
float cdfnormf(float x);
```

cdfnorminv

Description: The `cdfnorminv` function returns the inverse cumulative normal distribution function value.

errno:
EDOM, for finite or infinite `(x > 1) || (x < 0)`
ERANGE, for `x = 0 or x = 1`

Calling interface:
```
double cdfnorminv(double x);
float cdfnorminvf (float x);
```

compound

Description: The `compound` function computes the compound interest factor, $(1+x)^{y}$, where `x` is a rate and `y` is a period.

errno: ERANGE, for underflow and overflow conditions

Calling interface:
```
double compound(double x, double y);
long double compoundl(long double x, long double y);
float compoundf(float x, float y);
```

erf

Description: The `erf` function returns the error function value.

Calling interface:
```
double erf(double x);
long double erfl(long double x);
float erff(float x);
```

erfc

Description: The `erfc` function returns the complementary error function value.

errno: ERANGE, for underflow conditions

Calling interface:
```
double erfc(double x);
long double erfcl(long double x);
float erfcf(float x);
```

erfcx

Description: The `erfcx` function returns the scaled complementary error function value.

errno: ERANGE, for overflow conditions

Calling interface:
```
double erfcx(double x);
float erfcxf(float x);
```

erfcinv

Description: The `erfcinv` function returns the value of the inverse complementary error function of `x`.

errno: EDOM, for finite or infinite (x > 2) || (x < 0)

Calling interface:

```
double erfcinv(double x);
float erfcinvf(float x);
```

erfinv

Description: The `erfinv` function returns the value of the inverse error function of `x`.

errno: EDOM, for finite or infinite |x| > 1

Calling interface:

```
double erfinv(double x);
long double erfinvl(long double x);
float erfinvf(float x);
```

gamma

Description: The `gamma` function returns the value of the logarithm of the absolute value of gamma.

errno: ERANGE, for overflow conditions when x is a negative integer.

Calling interface:

```
double gamma(double x);
long double gammal(long double x);
float gammaf(float x);
```

gamma_r

Description: The `gamma_r` function returns the value of the logarithm of the absolute value of gamma. The sign of the gamma function is returned in the integer `signgam`.

Calling interface:

```
double gamma_r(double x, int *signgam);
long double gammal_r(long double x, int *signgam);
float gammaf_r(float x, int *signgam);
```

j0

Description: Computes the Bessel function (of the first kind) of `x` with order 0.

Calling interface:

```
double j0(double x);
long double j0l(long double x);
float j0f(float x);
```

j1

Description: Computes the Bessel function (of the first kind) of `x` with order 1.

Calling interface:

```
double j1(double x);
long double j1l(long double x);
float j1f(float x);
```

jn

Description: Computes the Bessel function (of the first kind) of `x` with order `n`.

Calling interface:

```
double jn(int n, double x);
long double jnl(int n, long double x);
float jnf(int n, float x);
```

lgamma

Description: The `lgamma` function returns the value of the logarithm of the absolute value of gamma.

errno: ERANGE, for overflow conditions, x=0 or negative integers.

Calling interface:

```
double lgamma(double x);
long double lgammal(long double x);
float lgammaf(float x);
```

lgamma_r

Description: The `lgamma_r` function returns the value of the logarithm of the absolute value of gamma. The sign of the gamma function is returned in the integer `signgam`.

errno: ERANGE, for overflow conditions, x=0 or negative integers.

Calling interface:

```
double lgamma_r(double x, int *signgam);
long double lgammal_r(long double x, int *signgam);
float lgammaf_r(float x, int *signgam);
```

tgamma

Description: The `tgamma` function computes the gamma function of `x`.

errno:

EDOM, for x=0 or negative integers.

ERANGE, for overflow conditions.

Calling interface:

```
double tgamma(double x);
long double tgammal(long double x);
float tgammaf(float x);
```

y0

Description: Computes the Bessel function (of the second kind) of `x` with order 0.

errno: EDOM, for x <= 0

Calling interface:

```
double y0(double x);
long double y0l(long double x);
float y0f(float x);
```

y1

Description: Computes the Bessel function (of the second kind) of `x` with order 1.

errno: EDOM, for x <= 0

Calling interface:

```
double y1(double x);
long double y1l(long double x);
float y1f(float x);
```

yn

Description: Computes the Bessel function (of the second kind) of `x` with order `n`.

errno: EDOM, for x <= 0

Calling interface:

```
double yn(int n, double x);
long double ynl(int n, long double x);
float ynf(int n, float x);
```

Nearest Integer Functions

Many routines in the Intel® C++ Compiler Classic Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The `mathimf.h` header file includes prototypes for Intel® C++ Compiler Classic Math Library functions.

The math library supports the following nearest integer functions:

ceil

Description: The `ceil` function returns the smallest integral value not less than `x` as a floating-point number.

Calling interface:

```
double ceil(double x);
long double ceill(long double x);
float ceilf(float x);
```

floor

Description: The `floor` function returns the largest integral value not greater than `x` as a floating-point value.

Calling interface:

```
double floor(double x);
long double floorl(long double x);
float floorf(float x);
```

llrint

Description: The `llrint` function returns the rounded integer value (according to the current rounding direction) as a `long long int`.

errno: ERANGE, for values too large

Calling interface:

```
long long int llrint(double x);
long long int llrintl(long double x);
long long int llrintf(float x);
```

llround

Description: The `llround` function returns the rounded integer value as a `long long int`.

errno: ERANGE, for values too large

Calling interface:

```
long long int llround(double x);
long long int llroundl(long double x);
long long int llroundf(float x);
```

lrint

Description: The `lrint` function returns the rounded integer value (according to the current rounding direction) as a `long int`.

errno: ERANGE, for values too large

Calling interface:

```
long int lrint(double x);
long int lrintl(long double x);
long int lrintf(float x);
```

lround

Description: The `lround` function returns the rounded integer value as a `long int`. Halfway cases are rounded away from zero.

errno: ERANGE, for values too large

Calling interface:

```
long int lround(double x);
long int lroundl(long double x);
long int lroundf(float x);
```

modf

Description: The `modf` function returns the value of the signed fractional part of `x` and stores the integral part at `*iptr` as a floating-point number.

Calling interface:

```
double modf(double x, double *iptr);
long double modfl(long double x, long double *iptr);
float modff(float x, float *iptr);
```

nearbyint

Description: The `nearbyint` function returns the rounded integral value as a floating-point number, using the current rounding direction.

Calling interface:

```
double nearbyint(double x);
long double nearbyintl(long double x);
float nearbyintf(float x);
```

rint

Description: The `rint` function returns the rounded integral value as a floating-point number, using the current rounding direction.

Calling interface:

```
double rint(double x);
long double rintl(long double x);
float rintf(float x);
```

round

Description: The `round` function returns the nearest integral value as a floating-point number. Halfway cases are rounded away from zero.

Calling interface:

```
double round(double x);
long double roundl(long double x);
float roundf(float x);
```

trunc

Description: The `trunc` function returns the truncated integral value as a floating-point number.

Calling interface:

```
double trunc(double x);
long double truncl(long double x);
float truncf(float x);
```

Remainder Functions

Many routines in the Intel® C++ Compiler Classic Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The `mathimf.h` header file includes prototypes for Intel® C++ Compiler Classic Math Library functions.

The math library supports the following remainder functions:

fmod

Description: The `fmod` function returns the value `x-n*y` for integer `n` such that if `y` is nonzero, the result has the same sign as `x` and magnitude less than the magnitude of `y`.

errno: EDOM, for y = 0

Calling interface:

```
double fmod(double x, double y);
long double fmodl(long double x, long double y);
float fmodf(float x, float y);
```

remainder

Description: The `remainder` function returns the value of `x REM y` as required by the IEEE standard.

errno: EDOM, for y = 0

Calling interface:

```
double remainder(double x, double y);
long double remainderl(long double x, long double y);
float remainderf(float x, float y);
```

remquo

Description: The `remquo` function returns the value of `x REM y`. In the object pointed to by `quo` the function stores a value whose sign is the sign of `x/y` and whose magnitude is congruent modulo 2^n of the integral quotient of `x/y`. `N` is an implementation-defined integer. For all systems, `N` is equal to 31.

errno: EDOM, for y = 0

Calling interface:

```
double remquo(double x, double y, int *quo);
long double remquol(long double x, long double y, int *quo);
float remquof(float x, float y, int *quo);
```

Miscellaneous Functions

Many routines in the Intel® C++ Compiler Classic Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The `mathimf.h` header file includes prototypes for Intel® C++ Compiler Classic Math Library functions.

The math library supports the following miscellaneous functions:

copysign

Description: The `copysign` function returns the value with the magnitude of `x` and the sign of `y`.

Calling interface:

```
double copysign(double x, double y);
long double copysignl(long double x, long double y);
float copysignf(float x, float y);
```

fabs

Description: The `fabs` function returns the absolute value of `x`.

Calling interface:

```
double fabs(double x);
long double fabsl(long double x);
float fabsf(float x);
```

fdim

Description: The `fdim` function returns the positive difference value, `x-y` (for `x > y`) or +0 (for `x <= to y`).

errno: ERANGE, for overflow conditions

Calling interface:

```
double fdim(double x, double y);
long double fdiml(long double x, long double y);
float fdimf(float x, float y);
```

finite

Description: The `finite` function returns 1 if `x` is not a `NaN` or +/- infinity. Otherwise 0 is returned.

Calling interface:

```
int finite(double x);
int finitel(long double x);
int finitef(float x);
```

fma

Description: The `fma` functions return `(x*y)+z`.

Calling interface:

```
double fma(double x, double y, double z);
long double fmal(long double x, long double y, long double z);
float fmaf(float x, float y, float z);
```

fmax

Description: The `fmax` function returns the maximum numeric value of its arguments.

Calling interface:

```
double fmax(double x, double y);
long double fmaxl(long double x, long double y);
float fmaxf(float x, float y);
```

fmin

Description: The `fmin` function returns the minimum numeric value of its arguments.

Calling interface:

```
double fmin(double x, double y);
long double fminl(long double x, long double y);
float fminf(float x, float y);
```

fpclassify

Description: The `fpclassify` function returns the value of the number classification macro appropriate to the value of its argument.

Return Value
0 (NaN)
1 (Infinity)
2 (Zero)
3 (Subnormal)
4 (Finite)

Calling interface:

```
int fpclassify(double x);
int fpclassifyl(long double x);
int fpclassifyf(float x);
```

isfinite

Description: The `isfinite` function returns 1 if `x` is not a NaN or +/- infinity. Otherwise 0 is returned.

Calling interface:

```
int isfinite(double x);
int isfinitel(long double x);
int isfinitef(float x);
```

isgreater

Description: The `isgreater` function returns 1 if `x` is greater than `y`. This function does not raise the invalid floating-point exception.

Calling interface:

```
int isgreater(double x, double y);
int isgreaterl(long double x, long double y);
int isgreaterf(float x, float y);
```

isgreaterequal

Description: The `isgreaterequal` function returns 1 if `x` is greater than or equal to `y`. This function does not raise the invalid floating-point exception.

Calling interface:

```
int isgreaterequal(double x, double y);
int isgreaterequall(long double x, long double y);
int isgreaterequalf(float x, float y);
```

isinf

Description: The `isinf` function returns a non-zero value if and only if its argument has an infinite value.

Calling interface:

```
int isinf(double x);
int isinfl(long double x);
int isinff(float x);
```

isless

Description: The `isless` function returns 1 if `x` is less than `y`. This function does not raise the invalid floating-point exception.

Calling interface:

```
int isless(double x, double y);
int islessl(long double x, long double y);
int islessf(float x, float y);
```

islessequal

Description: The `islessequal` function returns 1 if `x` is less than or equal to `y`. This function does not raise the invalid floating-point exception.

Calling interface:

```
int islessequal(double x, double y);
int islessequall(long double x, long double y);
int islessequalf(float x, float y);
```

islessgreater

Description: The `islessgreater` function returns 1 if `x` is less than or greater than `y`. This function does not raise the invalid floating-point exception.

Calling interface:

```
int islessgreater(double x, double y);
int islessgreaterl(long double x, long double y);
int islessgreaterf(float x, float y);
```

isnan

Description: The `isnan` function returns a non-zero value, if and only if `x` has a NaN value.

Calling interface:

```
int isnan(double x);
int isnanl(long double x);
int isnanf(float x);
```

isnormal

Description: The `isnormal` function returns a non-zero value, if and only if `x` is normal.

Calling interface:

```
int isnormal(double x);
int isnormall(long double x);
int isnormalf(float x);
```

isunordered

Description: The `isunordered` function returns 1 if either `x` or `y` is a NaN. This function does not raise the invalid floating-point exception.

Calling interface:

```
int isunordered(double x, double y);
int isunorderedl(long double x, long double y);
int isunorderedf(float x, float y);
```

maxmag

Description: The `maxmag` function returns the value of larger magnitude from among its two arguments, `x` and `y`. If `|x| > |y|` it returns `x`; if `|y| > |x|` it returns `y`; otherwise it behaves like `fmax(x,y)`.

Calling interface:

```
double maxmag(double x, double y);
float maxmagf(float x, float y);
```

minmag

Description: The `minmag` function returns the value of smaller magnitude from among its two arguments, `x` and `y`. If `|x| < |y|` it returns `x`; if `|y| < |x|` it returns `y`; otherwise it behaves like `fmin(x,y)`.

Calling interface:

```
double minmag(double x, double y);
float minmagf(float x, float y);
```

nan

Description: The `nan` function returns a quiet NaN, with content indicated through `tagp`.

Calling interface:

```
double nan(const char *tagp);
long double nanl(const char *tagp);
float nanf(const char *tagp);
```

nextafter

Description: The `nextafter` function returns the next representable value in the specified format after `x` in the direction of `y`.

errno: ERANGE, for overflow and underflow conditions

Calling interface:

```
double nextafter(double x, double y);
```

```
long double nextafterl(long double x, long double y);
float nextafterf(float x, float y);
```

nexttoward

Description: The `nexttoward` function returns the next representable value in the specified format after `x` in the direction of `y`. If `x` equals `y`, then the function returns `y` converted to the type of the function. Use the `Qlong-double` option (for C++ only) on Windows* operating systems for accurate results.

errno: ERANGE, for overflow and underflow conditions

Calling interface:

```
double nexttoward(double x, long double y);
long double nexttowardl(long double x, long double y);
float nexttowardf(float x, long double y);
```

signbit

Description: The `signbit` function returns a non-zero value, if and only if the sign of `x` is negative.

Calling interface:

```
int signbit(double x);
int signbitl(long double x);
int signbitf(float x);
```

significand

Description: The `significand` function returns the significand of `x` in the interval [1,2). For `x` equal to zero, NaN, or +/- infinity, the original `x` is returned.

Calling interface:

```
double significand(double x);
long double significandl(long double x);
float significandf(float x);
```

Complex Functions

Many routines in the Intel® C++ Compiler Classic Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The `mathimf.h` header file includes prototypes for Intel® C++ Compiler Classic Math Library functions.

The math library supports the following complex functions:

cabs

Description: The `cabs` function returns the complex absolute value of `z`.

Calling interface:

```
double cabs(double _Complex z);
long double cabsl(long double _Complex z);
float cabsf(float _Complex z);
```

cacos

Description: The `cacos` function returns the complex inverse cosine of `z`.

Calling interface:

```
double _Complex cacos(double _Complex z);
```

```
long double _Complex cacosl(long double _Complex z);
float _Complex cacosf(float _Complex z);
```

cacosh

Description: The `cacosh` function returns the complex inverse hyperbolic cosine of `z`.

Calling interface:

```
double _Complex cacosh(double _Complex z);
long double _Complex cacoshl(long double _Complex z);
float _Complex cacoshf(float _Complex z);
```

carg

Description: The `carg` function returns the value of the argument in the interval [-pi, +pi].

Calling interface:

```
double carg(double _Complex z);
long double cargl(long double _Complex z);
float cargf(float _Complex z);
```

casin

Description: The `casin` function returns the complex inverse sine of `z`.

Calling interface:

```
double _Complex casin(double _Complex z);
long double _Complex casinl(long double _Complex z);
float _Complex casinf(float _Complex z);
```

casinh

Description: The `casinh` function returns the complex inverse hyperbolic sine of `z`.

Calling interface:

```
double _Complex casinh(double _Complex z);
long double _Complex casinhl(long double _Complex z);
float _Complex casinhf(float _Complex z);
```

catan

Description: The `catan` function returns the complex inverse tangent of `z`.

Calling interface:

```
double _Complex catan(double _Complex z);
long double _Complex catanl(long double _Complex z);
float _Complex catanf(float _Complex z);
```

catanh

Description: The `catanh` function returns the complex inverse hyperbolic tangent of `z`.

Calling interface:

```
double _Complex catanh(double _Complex z);
long double _Complex catanhl(long double _Complex z);
float _Complex catanhf(float _Complex z);
```

ccos

Description: The `ccos` function returns the complex cosine of `z`.

Calling interface:

```
double _Complex ccos(double _Complex z);
long double _Complex ccosl(long double _Complex z);
float _Complex ccosf(float _Complex z);
```

ccosh

Description: The `ccosh` function returns the complex hyperbolic cosine of `z`.

Calling interface:

```
double _Complex ccosh(double _Complex z);
long double _Complex ccoshl(long double _Complex z);
float _Complex ccoshf(float _Complex z);
```

cexp

Description: The `cexp` function returns e^z (`e` raised to the power `z`).

Calling interface:

```
double _Complex cexp(double _Complex z);
long double _Complex cexpl(long double _Complex z);
float _Complex cexpf(float _Complex z);
```

cexp2

Description: The `cexp` function returns 2^z (2 raised to the power `z`).

Calling interface:

```
double _Complex cexp2(double _Complex z);
long double _Complex cexp2l(long double _Complex z);
float _Complex cexp2f(float _Complex z);
```

cexp10

Description: The `cexp10` function returns 10^z (10 raised to the power `z`).

Calling interface:

```
double _Complex cexp10(double _Complex z);
long double _Complex cexp10l(long double _Complex z);
float _Complex cexp10f(float _Complex z);
```

cimag

Description: The `cimag` function returns the imaginary part value of `z`.

Calling interface:

```
double cimag(double _Complex z);
long double cimagl(long double _Complex z);
float cimagf(float _Complex z);
```

cis

Description: The `cis` function returns the cosine and sine (as a complex value) of `z` measured in radians.

Calling interface:

```
double _Complex cis(double x);
```

```
long double _Complex cisl(long double z);
float _Complex cisf(float z);
```

cisd

Description: The `cisd` function returns the cosine and sine (as a complex value) of `z` measured in degrees.

Calling interface:

```
double _Complex cisd(double x);
long double _Complex cisdl(long double z);
float _Complex cisdf(float z);
```

clog

Description: The `clog` function returns the complex natural logarithm of `z`.

Calling interface:

```
double _Complex clog(double _Complex z);
long double _Complex clogl(long double _Complex z);
float _Complex clogf(float _Complex z);
```

clog2

Description: The `clog2` function returns the complex logarithm base 2 of `z`.

Calling interface:

```
double _Complex clog2(double _Complex z);
long double _Complex clog2l(long double _Complex z);
float _Complex clog2f(float _Complex z);
```

clog10

Description: The `clog10` function returns the complex logarithm base 10 of `z`.

Calling interface:

```
double _Complex clog10(double _Complex z);
long double _Complex clog10l(long double _Complex z);
float _Complex clog10f(float _Complex z);
```

conj

Description: The `conj` function returns the complex conjugate of `z` by reversing the sign of its imaginary part.

Calling interface:

```
double _Complex conj(double _Complex z);
long double _Complex conjl(long double _Complex z);
float _Complex conjf(float _Complex z);
```

cpow

Description: The `cpow` function returns the complex power function, x^y.

Calling interface:

```
double _Complex cpow(double _Complex x, double _Complex y);
long double _Complex cpowl(long double _Complex x, long double _Complex y);
float _Complex cpowf(float _Complex x, float _Complex y);
```

cproj

Description: The `cproj` function returns a projection of `z` onto the Riemann sphere.

Calling interface:

```
double _Complex cproj(double _Complex z);
long double _Complex cprojl(long double _Complex z);
float _Complex cprojf(float _Complex z);
```

creal

Description: The `creal` function returns the real part of `z`.

Calling interface:

```
double creal(double _Complex z);
long double creall(long double _Complex z);
float crealf(float _Complex z);
```

csin

Description: The `csin` function returns the complex sine of `z`.

Calling interface:

```
double _Complex csin(double _Complex z);
long double _Complex csinl(long double _Complex z);
float _Complex csinf(float _Complex z);
```

csinh

Description: The `csinh` function returns the complex hyperbolic sine of `z`.

Calling interface:

```
double _Complex csinh(double _Complex z);
long double _Complex csinhl(long double _Complex z);
float _Complex csinhf(float _Complex z);
```

csqrt

Description: The `csqrt` function returns the complex square root of `z`.

Calling interface:

```
double _Complex csqrt(double _Complex z);
long double _Complex csqrtl(long double _Complex z);
float _Complex csqrtf(float _Complex z);
```

ctan

Description: The `ctan` function returns the complex tangent of `z`.

Calling interface:

```
double _Complex ctan(double _Complex z);
long double _Complex ctanl(long double _Complex z);
float _Complex ctanf(float _Complex z);
```

ctanh

Description: The `ctanh` function returns the complex hyperbolic tangent of `z`.

Calling interface:

```
double _Complex ctanh(double _Complex z);
```

```
long double _Complex ctanhl(long double _Complex z);
float _Complex ctanhf(float _Complex z);
```

C99 Macros

Many routines in the Intel® C++ Compiler Classic Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

The `mathimf.h` header file includes prototypes for Intel® C++ Compiler Classic Math Library functions.

The math library and `mathimf.h` header file support the following C99 macros:

```
int fpclassify(x);
int isfinite(x);
int isgreater(x, y);
int isgreaterequal(x, y);
int isinf(x);
int isless(x, y);
int islessequal(x, y);
int islessgreater(x, y);
int isnan(x);
int isnormal(x);
int isunordered(x, y);
int signbit(x);
```

Miscellaneous Functions

Automatically-Aligned Dynamic Allocation

Automatically-Aligned Dynamic Allocation

Background

It is possible to tell the compiler that a data structure has a greater alignment requirement than its individual elements require. For example:

C++ standard syntax

```
class alignas(64) X {
    double elem[8];
};
```

GNU-compatible syntax

```
class __attribute__((aligned(64))) X {
    double elem[8];
};
```

Microsoft-compatible syntax

```
class __declspec(align(64)) X {
    double elem[8];
};
```

This is especially important for a structure that will be used with SIMD instructions, which typically require greater alignment than the individual data elements. The compiler will ensure that variables declared with such a type, either statically or on the stack, will be allocated with the appropriate alignment.

However, if an object of such a type is allocated dynamically, with a `new`-expression, the compiler was not previously able to do anything to ensure the appropriate alignment. That is because the C++ language requires that only very specific allocation methods be used, over which the programmer can take control if necessary, and none of those allocation methods are able to support specific alignment. They all assume that some alignment value is enough for everything, and guarantee that (and nothing more).

In the past, to ensure a greater alignment for a given type, a programmer had to take control of its allocation. One way to do that is by always allocating the memory separately with the appropriate alignment, and using a non-allocating placement `new`-expression. For example:

Incorrect alignment

```
new X
```

Correct alignment

```
new (_mm_malloc(sizeof(X), alignof(X))) X
```

However, this method is verbose, tedious, and error-prone.

Another way is to write class-specific allocation and deallocation functions—`operator new` and `operator delete`. For example:

```
class alignas(64) X {
  double elem[8];

public:
  void *operator new(size_t size){
    return _mm_malloc(size, alignof(X));
  }

  void operator delete(void *p){
    return _mm_free(p);
  }
};
```

This method is easier, because the changes are centralized in the class, instead of being distributed over the uses of the class. But to get it right in general is still fairly involved, because it requires defining several more functions, in case arrays of the class are dynamically allocated or `nothrow` allocation is used.

Automatically-Aligned Dynamic Allocation

In this release of the compiler, all that is necessary in order to get correct dynamic allocation for aligned data is to include a new header:

```
#include <aligned_new>
```

After this header is included, a `new`-expression for any aligned type will automatically allocate memory with the alignment of that type.

On Windows*, it is possible to direct the compiler to include a file at the beginning of the primary source file, without modifying the source, using the `/FI` command-line option.

Implementation Details

This section explains the language rules for the new feature. If a program needs to take control of dynamic allocation and deallocation of aligned data for some reason other than alignment, this section explains how it can be done.

Header <aligned_new> defines several new alignment-aware allocation and deallocation functions, each of which takes an alignment argument:

```
void *operator new    (size_t, align_val_t);
void *operator new    (size_t, align_val_t, nothrow_t const &);
void operator delete  (void *, align_val_t);
void operator delete  (void *, align_val_t, nothrow_t const &);
void *operator new[]  (size_t, align_val_t);
void *operator new[]  (size_t, align_val_t, nothrow_t const &);
void operator delete[](void *, align_val_t);
void operator delete[](void *, align_val_t, nothrow_t const &);
```

The type `align_val_t` is declared internally by the compiler as if by a declaration like this:

```
namespace std {
  enum class align_val_t: size_t;
};
```

In other words, `std::align_val_t` is a scoped enumeration type, which can not be implicitly converted to an integer type, but has the same range and representation as `std::size_t`.

When the compiler processes a `new`-expression for a type whose alignment is greater than `(2 * sizeof(void *))`, it builds an argument list according to the normal C++ rules, but with an additional alignment argument of type `align_val_t` following the size argument (followed by the placement arguments from the `new`-expression, if any). It then uses overload resolution to try to find an alignment-aware `operator new` or `operator new[]` function that can be called with those arguments. If no alignment-aware function is found, the alignment argument is removed from the argument list, and overload resolution is attempted again. An error is reported if this second attempt fails.

Class-specific Allocation and Deallocation Functions

If a program already provides class-specific allocation and deallocation functions for an aligned class, including <aligned_new> will not change the behavior, because class-specific functions take precedence over global functions, and <aligned_new> defines only global functions.

Unless class-specific allocation and deallocation functions are written for a base class of a class hierarchy containing classes with different alignments, it is probably not necessary to write alignment-aware allocation and deallocation functions that take an alignment argument; the appropriate alignment can instead be built into the class-specific allocation and deallocation functions.

Replacing Global Allocation and Deallocation Functions

> **NOTE** If a program defines its own global allocation and deallocation functions, replacing the ones from the standard library, and uses a non-placement `new`-expression to allocate aligned data, and <aligned_new> is included before the point of such a `new`-expression, **the behavior of the program will change**. The allocation will no longer use the program's replacement allocation functions, but instead Intel's provided alignment-aware allocation functions. **In a program that replaces the global allocation and deallocation functions, care must be used to decide whether to include <aligned_new>.**

If a program wants to replace the global allocation and deallocation functions, and also wants to take advantage of the compiler's ability to provide an alignment argument to such functions, <aligned_new> should not be included, because it provides inline definitions of the alignment-aware functions, which will conflict with or take precedence over the program's definitions. Instead, <aligned_new> should be used as a guide to write program-specific declarations and definitions of the alignment-aware functions that need to be replaced.

Pointer Checker

Pointer Checker Overview

The pointer checker is not supported on macOS systems.

This feature requires installation of another product. For more information, see Feature Requirements.

The pointer checker is a debugging feature that helps you find buffer overruns in applications. The feature performs bounds checking for memory accesses through pointers and identifies any out-of-bounds access in pointer-checker enabled code. The pointer checker can also detect dangling pointers, that is, pointers that point to memory that has been freed. When this detection is enabled, using a dangling pointer in an indirect access will also cause an out-of-bounds error.

The C and C++ languages define semantics for memory access for pointers. However, many applications still make out-of-bounds memory accesses and these accesses can go undetected, risking data corruption and increasing vulnerability to malicious attacks. The pointer checker provides full checking of all memory accesses through pointers and catches out-of-bounds memory accesses before memory corruption occurs. When you compile your code with the pointer checker enabled, it identifies and reports out-of-bounds memory accesses.

The pointer checker is designed for use during application testing and debugging. Because it adds overhead in terms of the size and execution time of a program, you will want to deploy programs with the pointer checker disabled.

Your application can contain both pointer checker enabled code as well as code that is not enabled. The pointer checker allows this co-existence because it does not change the data structure layout of functions during its checking.

Pointer Checker Feature Summary
Feature Requirements

Pointer Checker Feature Summary

The pointer checker is not supported on macOS systems.

The pointer checker provides a number of related elements, summarized in the following table.

Element	Description
Compiler Options:	
`[Q]check-pointers`	Enables the pointer checker and adds the associated libraries. This compiler option enables checking of all indirect accesses through pointers and accesses to arrays. The possible option keywords are [`none` | `write` | `rw`], where: • **none**: Disables the pointer checker (default). • **write**: Checks bounds for only writes through pointers. • **rw**: Checks bounds for reads and writes through pointers. If the compiler determines that an access is safe during optimization, then the compiler removes the pointer checking code. See Checking Bounds.
`[Q]check-pointers-dangling`	Enables checking for dangling pointer references.

Element	Description
	The possible option keywords are [none | heap | stack | all], where: • **none**: Disables checking for dangling pointer references (default). • **heap**: Checks for dangling pointer references on the heap. • **stack**: Checks for dangling pointer references on the stack. • **all**: Checks for dangling pointer references on both the heap and the stack. **NOTE** To use this option, you must also use the [Q]check-pointers compiler option. This option cannot be used with [Q]check-pointers-mpx. See Checking for Dangling Pointers.
[Q]check-pointers-undimensioned	Enables the checking of bounds for arrays without dimensions. **NOTE** To use this option, you must also use the [Q]check-pointers compiler option. See Checking Arrays.
[Q]check-pointers-narrowing	Determines whether the compiler enables or disables the narrowing of pointers to structure fields. Narrowing restricts a field pointer so that it can only legally point to that field. Enables or disables the compiler narrowing of pointers to structure fields. The default is enabled for narrowing pointer references. Disabling this feature can improve Pointer Checker compatibility with non-ANSI compliant code. To disable the narrowing of pointers to structure fields, specify the negative form of the option. **NOTE** To use this option, you must also use the [Q]check-pointers compiler option.
check-pointers-mpx, Qcheck-pointers-mpx	Determines whether the compiler checks bounds for memory access through pointers on processors supporting Intel® Memory Protection Extensions (Intel® MPX). It enables checking of all indirect accesses through pointers, and all array accesses. Specifies what type of bounds checking occurs. The possible option keywords are [none | write | rw], where: • **none**: Disables the pointer checker (default). • **write**: Checks bounds for only writes through pointers. • **rw**: Checks bounds for reads and writes through pointers. The compiler may optimize these checks away when it can determine that an access is safe.

Element	Description
	This option cannot be used with `[Q]check-pointers-dangling`. If you specify option `[Q]check-pointers` along with option `[Q]check-pointers-mpx`, `[Q]check-pointers-mpx` takes precedence. On supported Windows* target platforms, MPX instructions can also be accessed using MPX intrinsic functions and the `__declspec(mpx)` feature. For more details, please see the Intel Memory Protection Extensions Enabling Guide (https://software.intel.com/sites/default/files/managed/9d/f6/Intel_MPX_EnablingGuide.pdf).
Intrinsics:	
`void * __chkp_lower_bound(void **)`	Returns the lower bound associated with the pointer. See Writing a Wrapper.
`void * __chkp_upper_bound(void **)`	Returns the upper bound associated with the pointer. See Writing a Wrapper.
`void * __chkp_kill_bounds(void *p)`	Removes the bounds information to allow the pointer specified in the argument to access all memory. Use this function for a pointer from a non-enabled module that will be used in an enabled module where you cannot determine the bounds of the pointer. The function ensures that the pointer created from a non-enabled module does not inherit the bounds from another pointer that was in the same memory address. The return value is a pointer without bounds information. See Working with Enabled and Non-Enabled Modules.

`void * __chkp_make_bounds(void *p, size_t size)`	Creates new bounds information within the allocated memory address for the pointer in the argument, replacing any previously associated bounds information. The new bounds are:
	`p = __chkp_make_bounds(q, size)`
	`    // lower_bound(p) = (char *)q`
	`    // upper_bound(p) = lower_bound(p) + size`
	See Checking Custom Memory Allocators.

Reporting Function:	
`void __chkp_report_control(__chkp_report_option_t option, __chkp_callback_t callback)`	Determines how errors are reported. See Finding and Reporting Out-of-Bounds Errors.
Enumeration:	
`__chkp_report_option_t`	Controls how out-of-bounds error are reported. This enumeration is declared in the header file `chkp.h`. See Finding and Reporting Out-of-Bounds Errors.
Environment Variable:	
`INTEL_CHKP_REPORT_MODE`	Changes the pointer checker reporting mode at runtime. See Finding and Reporting Out-of-Bounds Errors.
Header file:	

Element	Description
chkp.h	Defines intrinsic and reporting functions. The header file is located in the <install-dir>\include directory.

Checking Bounds

Using the Pointer Checker

Checking Bounds

The pointer checker is not supported on macOS systems.

The pointer checker checks indirect accesses through pointers for accesses that are out of bounds.

Checking Bounds on Read/Write Operations

To check the bounds of pointers, compile your module with [Q]check-pointers compiler option, specifying the rw argument.

You can also check bounds by specifying the write argument. This also checks the bounds of pointers, but only for pointer write operations.

Consider the case where you create an array with ten elements using the malloc() function and then you write a character to each array element:

Example: Writing to Each Array Element

```
char *buf = malloc(10);
for (int i=0; i<=10; i++) { buf[i] = ‘A’ + i; }
```

The array has ten elements, but the loop iterates eleven times. On the eleventh iteration, the function writes a character to the eleventh element of the array, which is outside of the allocated memory. Regardless of whether you specify bounds checking for read and write operations or only write operations, the pointer checker will report an out-of-bounds error. Even in the case of a statically allocated buffer, the pointer checker will still report an error. Consider this case:

Example: Out-of-bounds Error with a Statically Allocated Buffer

```
fprintf(stderr, "buf[%d]=%d\n",i,buf[i]);
```

Here, the reference to buf[i] is a read (or load) operation. Therefore, an out-of-bounds error will not be reported if you specified pointer checking only for write operations.

Pointer Arithmetic and Pointer Checking

Pointer arithmetic does not affect the pointer checker. A pointer can go out of range as long as the pointer does not make an indirect reference to an out of range address.

In the case where you create an array with 100 elements, the following applies:

Example: Pointer Arithmetic with Pointer Checking

```
char *p = malloc(100);
  p += 200;       // pointer is out of range, but no error
  p[-101] = 0; // access is still in range, it is the original p[99]
  p[0] = 0;    // out-of-bounds error occurs here, because it is original p[200]
```

check-pointers, Qcheck-pointers compiler option

Checking for Dangling Pointers

The pointer checker is not supported on macOS systems.

When dangling pointer checking or heap is enabled, the compiler uses a wrapper for the C runtime function free() and the C++ delete operator. These wrappers find all pointers that point to the block being freed, and change their bounds so that any access through the pointer will cause a bound violation. The bounds of these dangling pointers are actually set to:

- lower_bound(*p*) = 2;
- upper_bound(*p*) = 0;

If your program gets a bound violation with these bounds, it is the result of a reference through a dangling pointer.

When dangling pointer checking is enabled for stack, the compiler finds all pointers that point to the locals of the function and changes their bounds in the same way as heap pointers above, just before the function exits.

If you have a custom memory allocator, you can enable it to do dangling pointer checking. The free() function of your custom memory allocator should call this function in the pointer checker runtime code:

```
void __chkp_invalidate_dangling(void *ptr, size_t size);
```

This function is declared in the chkp.h file. You must include that header file to use this function because it uses a custom call interface.

Example

```
#include <chkp.h>
     void my_free(void *ptr) {
      size_t size = my_get_size(ptr);
     // do the free
 __chkp_invalidate_dangling(ptr, size);
     }
```

You can also enabled dangling pointer checking in any function you use to override the C++ delete operator.

See Also

check-pointers-dangling, Qcheck-pointers-dangling compiler option

Checking Arrays

The pointer checker is not supported on macOS systems.

The C and C++ language allows you to define arrays in another module with the `extern` keyword. These arrays can be defined without specifying the dimensions.

Example: Creating an Undimensioned Array

```
extern char an_undimensioned_array [];
```

The compiler allows more than one definition for externally defined arrays. During link time, the compiler uses the array definition with the largest bounds.

To check these arrays, the compiler defines a global symbol that marks the end of the array. However, checking undimensioned arrays can lead to a multiple defined linker error. To fix this linker error, do one of the following:

- Use only one array definition.
- Use the negative form of the `[Q]check-pointers-undimensioned` compiler option to disable checking arrays without bounds.

> **NOTE**
> This compiler option suppresses checking in the module that declares an array without bounds. The pointer checker will still check the arrays in modules that actually define the arrays with bounds.

See Also

check-pointers-undimensioned, Qcheck-pointers-undimensioned compiler option

Working with Enabled and Non-Enabled Modules

The pointer checker is not supported on macOS systems.

An enabled module is a module compiled with the pointer checker option enabled, while a non-enabled module is a module compiled with this compiler option disabled.

If you write a pointer to memory or return a pointer from a non-enabled module, the pointer may get incorrect bounds information. If you use this pointer with the incorrect bounds information in an enabled module, the pointer checker will report an incorrect out-of-bounds error because the bounds do not correspond to the pointer.

To minimize this issue, the pointer checker stores a copy of the pointer along with the bounds information. When the pointer is loaded into memory, the value of the pointer is compared with the value of the pointer copy. If these two values match, the bounds information is assumed to be correct and is then used. However, if the two values do not match, the bounds are set to allow access to any memory.

The pointer checker can still report an out-of-bounds error if a pointer from a non-enabled module matches the pointer copy stored with the bounds information.

For example, consider the case where you create the following pointer by using a run-time library function from a non-enabled module:

Example: Pointer Created with RTL Function

```
p = my_realloc(p, old_size + 100);
```

If the memory allocator can simply extend the memory allocated to `p`, and then returns the same pointer, an enabled module could use this pointer with the old bounds information. The pointer checker then reports an out-of-bounds error because this feature does not know about the extension created by the `realloc()` function.

To prevent incorrect out-of-bounds errors when you have both enabled and non-enabled modules, do one of the following:

- Remove the bounds information from the pointer by using the `__chkp_kill_bounds()` intrinsic function
- Set the correct bounds information by using the `__chkp_make_bounds()` intrinsic function in an enabled module.

Removing the Bounds Information

When you remove the bounds information, you disable pointer checking on this pointer. You can remove the bounds information by using the `__chkp_kill_bounds()` intrinsic function.

Example: Removing Bounds Information with __chkp_kill_bounds()

```
void * unknown_pointer_returning_function() {
   ...
   // Use the intrinsic function in the return pointer
   return __chkp_kill_bounds(the_ptr);
}
```

Setting the correct bounds information

You can use the `__chkp_make_bounds()` intrinsic function to set the correct bounds information for a pointer.

For example, you use the Windows* `HeapAlloc()` function to create a pointer. Since this operating system function is from a non-enabled module, the pointer from this function will not have the correct bounds information.

To get a pointer with the correct bounds information, use the `__chkp_make_bounds()` intrinsic function in the return value:

Example: Obtaining a Pointer with __chkp_make_bounds()

```
void * myalloc(size_t size){ return __chkp_make_bounds(HeapAlloc(MyHeap, flags, size), size); }
```

Storing Bounds Information

The pointer checker is not supported on macOS systems.

The pointer checker stores bounds information in a bounds table located in a memory address that is not adjacent to the memory address of the pointer. The pointer checker calculates this address by using the address of the pointer.

Because the bounds information is being stored in a separate memory address, use of the pointer checker in this module does not affect the data structure layouts and stack frames. You can check the bounds of pointers in enabled modules. Non-enabled modules will still work properly although this feature will not check the pointers in these modules.

When a pointer is loaded in a register, the compiler also loads the bounds from the bounds table. When a pointer is stored from a register, the compiler stores the bounds information in the bounds table.

Passing and Returning Bounds

The pointer checker is not supported on macOS systems.

When you pass a pointer to a function, the pointer checker also passes the bounds information associated with the pointer. The feature uses the following methods to pass and return arguments:

- If you pass a pointer on the stack, the pointer is in a memory location, so the pointer checker stores the bounds information when you compile your enabled module. The bounds information is stored in the bounds table entry associated with the address of the pointer.
- If you pass a pointer on a register, the compiler uses a location in thread local storage to pass the bounds. There is one such location associated with each register in which a pointer can be passed. This same location is used to return the bounds when a pointer is returned by a function.

Checking Run-Time Library Functions

The pointer checker is not supported on macOS systems.

The pointer checker provides checking on C run-time library functions that manipulate memory through pointers. It uses a library of functions that either replace the run-time library function, or wrap them with the appropriate pointer checking mechanisms.

For functions that allocate memory, such as the `malloc()` function or various C++ new functions, the wrapper function create bounds information for the pointers returned by the memory allocator.

For functions that copy memory, such as the `memcpy()` function, the memory address may contain the pointers along with their associated bounds information. The wrapper functions check for out-of-bounds accesses and ensure that any bounds associated with the copied memory are also copied.

The point checker C run-time function wrappers are located in the `libchkpwrap` library. To determine which C run-time routines are wrapped, you can examine the entry points in the library. For example, the following will yield a list of entry points:

Example

```
// Linux*
  % nm libchkpwrap.a | egrep 'T __chkp_'

// Windows* (x86)
  dumpbin /symbols libchkpwrap.lib | egrep 'SECT.*External.*
  [_]*__chkp_'
```

The returned list will include entry points that signify wrappers. For example, `__chkp_strcpy` is the wrapper for `strcpy`.

Writing a Wrapper

The pointer checker is not supported on macOS systems.

You can write your own wrappers for run-time library functions. Typically, you would use one or more of the pointer checker intrinsics.

Example: Allocation Wrapping with __chkp_make_bounds

```
extern void *wrap_malloc(size_t bytes) {
    void* ppp;
    ppp = malloc(bytes);
    if (ppp) { ppp = (void*)__chkp_make_bounds(ppp, bytes);
    } else { ppp = (void*)0;}
    return ppp;
}
```

The next example shows a wrapper that checks the validity of the pointer passed by performing writes to the first and last addresses that the C run-time routine will write. This will cause out of bounds events if necessary, while still allowing optimized handling of the C run-time library call.

Example: Checking without using Pointer Checker Intrinsics

```
extern void *wrap_memset(void *dst, int c, size_t size) {
    if (size > 0) {
      *(char *)dst = c;          // write to first address
      *((char*)dst+size-1) = c;  // write to last address
      (void)memset(dst, c, size);
    }
    return dst;
}
```

Alternatively, you can perform the checking directly by comparing to the bounds associated with the pointer. In this case, you must first make sure that the bounds are meaningful. You can use the `__chkp_upper_bound` and `__chkp_lower_bound` intrinsics for this purpose.

Example: Upper and Lower Bound Intrinsics

```
extern void *wrap_memset(void *dst, int c, size_t size) {
  if (size > 0) {
    char *ub = __chkp_upper_bound(&dst);
    if ((intptr_t)ub != (intptr_t)-1) {
      char *lb = __chkp_lower_bound(&dst);
      char *max = (char*)dst+size-1;
        if (dst < lb)
           *(char*)dst = c;  // cause bounds violation
        if (max > ub)
           *(char*)max = c;  // cause bounds violation
      }
      (void)memset(dst, c, size);
    }
    return dst;
}
```

Checking Custom Memory Allocators

The pointer checker is not supported on macOS systems.

Many C and C++ applications use standard memory allocation functions to allocate large chunks of memory and then define their own custom memory allocation functions to allocate these large chunks of memory into smaller chunks. If you use the pointer checker on a module that contains custom memory allocation functions, every memory allocation from these custom functions will have the bounds information from the large chunk of memory.

To create the correct bounds information for a pointers in a custom memory allocator function, use the `__chkp_make_bounds()` intrinsic function.

For example, consider the case where you create a custom memory allocator function that returns a pointer. To add the exact bounds information to the return pointer, use the `__chkp_make_bounds()` intrinsic function in the return value:

Adding exact bounds information to a return pointer

```
void *myalloc(size_t size) {
      // Code to do allocate the large chunk of memory into small chunks.
      // Add bounds information to the pointer
   return __chkp_make_bounds(p, size);
}
```

NOTE
If you override the `new` operator in C++, you can use the same technique to give bounds information to the return pointer.

Checking Multi-Threaded Code

The pointer checker is not supported on macOS systems.

A common assumption is that reading or writing a pointer is an atomic operation that cannot be interrupted by starting another thread. This is not the case with using the pointer checker to check pointers in multi-threaded modules.

When you read or write a pointer from memory, the bounds information associated with the pointer must also be read or written. Reading and writing bounds information takes multiple instructions. While a thread is in the process of writing a pointer and its bounds, it could be swapped out for another thread. If that thread then writes to the same pointer, you can end up with a pointer and bounds information that are not synchronized—the pointer is from one thread and the bounds information is from another thread.

To synchronize the pointer and bounds information in multi-threaded code, use a locking mechanism, such as a mutex or critical section when reading or writing a pointer in memory locations shared by more than one thread. Typically, accesses to shared memory are already protected this way.

If your application relies on a pointer read or a pointer write that is atomic and performs reads or writes to shared pointers without such locking, you can get extraneous bounds violations unless you protect these accesses.

How the Compiler Defines Bounds Information for Pointers

The pointer checker is not supported on macOS systems.

The following defines how the compiler determines the bound information for pointers.

NOTE
In each section, `lower_bound(`*p*`)` refers to the lower bound associated with *p* and `upper_bound(`*p*`)` refers to the upper bound associated with *p*.

Pointers created by the alloca() function

```
p = alloca(size);
    // lower_bound (p) is (char *)p
    // upper_bound (p) is lower_bound(p) + size - 1
```

Pointers created by the calloc() function

```
p = calloc(num, size);
    // lower_bound(p) is (char *)p
    // upper_bound(p) is lower_bound(p) + size * num - 1
```

Pointers created by the `malloc()` function

`p = malloc(size);`
`    // lower_bound(p) is (char *)p`
`    // upper_bound(p) is lower_bound(p) + size - 1`

Pointers created by casting

`p = (T *)q;`
`    // lower_bound(p) is lower_bound(q)`
`    // upper_bound(p) is upper_bound(q)`

Casting a pointer does not affect the bounds of a pointer. If you cast a pointer to a new type that is larger than the bounds associated with the original pointer, you will get an out-of-bounds error when you try to access any member or element outside the original bounds. If you cast a pointer to a smaller type than the original pointer, you can still access the original data.

Pointers created for a variable length array in a structure

```
typedef struct {
    int num;
    int a[];
} T;

q = malloc(sizeof(T) + sizeof(int) * num);
p = &q->a;
    // lower_bound(p) is (char *)&q->a
    // upper_bound(p) is upper_bound(q)
```

When you define an array as the last member of a structure, the upper bound is not narrowed and is allowed to access all of the array elements allocated by the `malloc()` function.

Pointers defined by the address (&) operator

```
p = &v;
    // lower_bound(p) is (char *)&v
    // upper_bound(p) is (char *)&v + sizeof(v) - 1

p = &v.m;
    // lower_bound(p) is (char *)&v + offsetof(typeof(v),  m)
    // upper_bound(p) is lower_bound(p) + sizeof(v.m) - 1

p = &q->m;
    // lower_bound(p) is (char *)q + offsetof(typeof(*q),  m)
    // upper_bound(p) is lower_bound(p) + sizeof(q->m) - 1
```

NOTE
The bounds information is narrowed to the size of the member when you point to a member of a structure, union, or class.

Pointers defined by the new operator

```
p = new T;
    // lower_bound(p) is (char *)p
    // upper_bound(p) is lower_bound(p) + sizeof(T) - 1
```

Pointers defined by the addresses in an array

```
T a[X][Y];

p = a;
p = &a[x];
p = &a[x][y];
    // lower_bound(p) is (char *)a
    // upper_bound(p) is lower_bound(p) + sizeof(a) - 1
```

When you take the address of an element of an array or the address of a single row of a multi-dimensioned array, the bounds are not narrowed to the size of the element. You can increment or decrement the pointer throughout the array.

Incrementing and Decrementing Pointers

```
p = &a[x][y].m;
    // lower_bound(p) is (char *)&a[n][m] + offsetof(T, m)
    // upper_bound(p) is lower_bound(p) + sizeof(T.m) - 1
```

When you take the address of a member of an element, the bounds are narrowed to the size of the member.

Pointers defined by pointer copies

```
p = q;
p = q + expr;
p = q - expr;
    // lower_bound(p) is lower_bound(q)
    // upper_bound(p) is upper_bound(q)
```

The bounds are copied from *q*. Offsetting the pointer on the right does not affect the bounds.

Pointers defined by incrementing or decrementing a pointer

```
p++;
p--;
++p;
--p;
p += expr;
p -= expr;
```

The bounds do not change when you increment or decrement a pointer.

Finding and Reporting Out-of-Bounds Errors

The pointer checker is not supported on macOS systems.

The pointer checker includes the `__chkp_report_control()` library function and the `__chkp_report_option_t` enumeration to allow you to control how errors are reported. The function and enumeration are declared in the header file `chkp.h`.

The report control enumeration has one of the following values:

Enum Value	Action
`__CHKP_REPORT_NONE`	Do nothing.
`__CHKP_REPORT_BPT`	Execute a breakpoint interrupt. If you specify this value, the pointer checker will issue a breakpoint for any out-of-bounds error that it finds. If you are using a debugger, the breakpoint will trap into the debugger so that you can determine where the error occurred. You can then use the features of the debugger to determine the cause of the error.
`__CHKP_REPORT_LOG`	Log the error and continue; the compiler will report each out-of-bounds pointer it finds.
`__CHKP_REPORT_TERM`	Log the error and exit the program; the compiler will only report the first bounds violation and then terminate.
`__CHKP_REPORT_CALLBACK`	Call a user defined function; the compiler will invoke a user-defined function to deal with a bounds error.
`__CHKP_REPORT_TRACEBACK _BPT`	Print a traceback including source file and line number for the instruction where the out-of-bounds error occurred, then execute a breakpoint interrupt. **NOTE** Specify the `traceback` compiler option to obtain better traceback information, including routine names.
`__CHKP_REPORT_TRACE_LOG`	Log the error and continue; the log will include traceback information for each out-of-bounds error. This is the default reporting mode. **NOTE** Specify the `traceback` compiler option to obtain better traceback information, including routine names.
`__CHKP_REPORT_TRACE_TERM`	Log the error and terminate; the log will include traceback information for each out-of-bounds error. Only the first bounds error will be reported. **NOTE** Specify the `traceback` compiler option to obtain better traceback information, including routine names.
`__CHKP_REPORT_TRACE_CALLBACK`	Log the error and call a user-defined routine; the log will include traceback information for each out-of-bounds error. **NOTE** Specify the `traceback` compiler option to obtain better traceback information, including routine names.
`__CHKP_REPORT_OOB_STATS`	Emit statistics for the bounds violation; Currently, this is a count of the out-of-bounds errors.

Enum Value	Action
__CHKP_REPORT_USE_ENV_VAR	Use the environment variable INTEL_CHKP_REPORT_MODE to specify the reporting mode. If the environment variable is not set, the default reporting mode is used.

Changing the Reporting Mode

To change the reporting mode from the default __CHKP_REPORT_TRACE_LOG:

1. Include chkp.h in your program source.
2. Add a call to the report control routine __chkp_report_control() (before any pointer references are made), specifying one of the enum values.

   For example, to report all bounds errors, specify the following:

```
__chkp_report_control(__CHKP_REPORT_LOG, 0);
```

In the above, the first parameter to the routine is the enum value and the second parameter is 0, except in the case of the __CHKP_REPORT_CALLBACK enum value, which requires the name of a user-defined callback routine as the second parameter.

You can also change the reporting mode using the environment variable INTEL_CHKP_REPORT_MODE. This allows you to change the reporting mode without recompiling your code. To use the environment variable, do the following:

1. Add an include of chkp.h in your program source.
2. Add a call to the report control routine __chkp_report_control() (before any pointer references are made), specifying __CHKP_REPORT_USE_ENV_VAR.
3. Set the INTEL_CHKP_REPORT_MODE environment variable to the desired report mode. For example:

```
export INTEL_CHKP_REPORT_MODE=__CHKP_REPORT_OOB_STATS
```

NOTE
The INTEL_CHKP_REPORT_MODE environment variable is valid only if a call to __chkp_report_control has been made with the report mode set to __CHKP_REPORT_USE_ENV_VAR. Otherwise, it is ignored.

If you specify the report mode to be __CHKP_REPORT_USE_ENV_VAR and the INTEL_CHKP_REPORT_MODE environment variable is not set, the default report mode (__CHKP_REPORT_TRACE_LOG) is used.

Tools

PGO Tools

PGO Tools Overview

This section describes the tools that take advantage of or support the Profile-guided Optimizations (PGO) available in the compiler.

- Code coverage Tool
- Test prioritization Tool
- Profmerge and proforder Tools

Code Coverage Tool

The code coverage tool provides software developers with a view of how much application code is exercised when a specific workload is applied to the application. To determine which code is used, the code coverage tool uses Profile-guided Optimization (PGO) options and optimizations. The major features of the code coverage tool are listed below:

- Visually presenting code coverage information for an application with a customizable code coverage coloring scheme
- Displaying dynamic execution counts of each basic block of the application
- Providing differential coverage, or comparison, profile data for two runs of an application

The information about using the code coverage tool is separated into the following sections:

- Code coverage tool Requirements
- Visually Presenting Code Coverage for an Application
- Excluding Code from Coverage Analysis
- Exporting Coverage Data

The tool analyzes static profile information generated by the compiler, as well as dynamic profile information generated by running an instrumented form of the application binaries on the workload. The tool can generate an HTML-formatted report and export data in both text-, and XML-formatted files. The reports can be further customized to show color-coded, annotated, source-code listings that distinguish between used and unused code.

The code coverage tool is available on all supported Intel architectures on Linux*, Windows*, and macOS operating systems.

You can use the tool in a number of ways to improve development efficiency, reduce defects, and increase application performance:

- During the project testing phase, the tool can measure the overall quality of testing by showing how much code is actually tested.
- When applied to the profile of a performance workload, the code coverage tool can reveal how well the workload exercises the critical code in an application. High coverage of performance-critical modules is essential to taking full advantage of the Profile-Guided Optimizations that Intel Compilers offer.
- The tool provides an option useful for both coverage and performance tuning, enabling developers to display the dynamic execution count for each basic block of the application.
- The code coverage tool can compare the profile of two different application runs. This feature can help locate portions of the code in an application that are unrevealed during testing but are exercised when the application is used outside the test space, for example, when used by a customer.

Code Coverage Tool Requirements

To run the code coverage tool on an application, you must have following items:

- The application sources.
- The .spi file generated by the Intel® compiler when compiling the application for the instrumented binaries using the `-prof-gen=srcpos` (Linux and macOS) or `/Qprof-gen:srcpos` (Windows) option.

NOTE
Use the `-[Q]prof-gen:srcpos` option if you intend to use the collected data for code coverage and profile feedback. If you are only interested in using the instrumentation for code coverage, use the `/Qcov-gen` option. Using the `/Qcov-gen` option saves time and improves performance. This option can be used only on Windows platform for all architectures.

- A `pgopti.dpi` file that contains the results of merging the dynamic profile information (.dyn) files, which is most easily generated by the profmerge tool. This file is also generated implicitly by the Intel® compilers when compiling an application with `[Q]prof-use` options with available .dyn and .dpi files.

Using the Tool

The tool uses the following syntax:

Tool Syntax
`codecov [-codecov_option]`

where `-codecov_option` is one or more optional parameters specifying the tool option passed to the tool. The available tool options are listed in the code coverage tools Options section. If you do not use any additional tool options, the tool will provide the top-level code coverage for the entire application.

In general, you must perform the following steps to use the code coverage tool:

1. Compile the application using `-prof-gen=srcpos` (Linux and macOS) or `/Qprof-gen:srcpos` (Windows), and/or `/Qcov-gen` (Windows) option.

This step generates an instrumented executable and a corresponding static profile information (`pgopti.spi`) file when the `[Q]prof-gen=srcpos` option is used. When the `/Qcov-gen` option is used, minimum instrumentation only for code coverage and generation of .spi file is enabled.

> **NOTE**
> You can specify both the `/Qprof-gen=srcpos` and `/Qcov-gen` options on the command line. The higher level of instrumentation needed for profile feedback is enabled along with the profile option for generating the .spi file, regardless of the order the options are specified on the command line.

2. Run the instrumented application.

This step creates the dynamic profile information (.dyn) file. Each time you run the instrumented application, the compiler generates a unique .dyn file either in the current directory or the directory specified in by the -prof-dir (Linux or macOS) or /Qprof-dir (Windows) option, or PROF_DIR environment variable. On Windows, you can use the /Qcov-dir or COV_DIR environment variable. These have the same meaning as /Qprof-dir and PROF_DIR.

3. Use the profmerge tool to merge all the .dyn files into one .dpi (`pgopti.dpi`) file.

This step consolidates results from all runs and represents the total profile information for the application, generates an optimized binary, and creates the dpi file needed by the code coverage tool.

You can use the profmerge tool to merge the .dyn files into a .dpi file without recompiling the application. The profmerge tool can also merge multiple .dpi files into one .dpi file using the `profmerge -a` option. Select an alternate name for the output .dpi file using the `profmerge -prof_dpi` option.

> **Caution**
> The profmerge tool merges all .dyn files that exist in the given directory. Confirm that unrelated .dyn files, which may remain from unrelated runs, are not present. Otherwise, the profile information will be skewed with invalid profile data, which can result in misleading coverage information and adverse performance of the optimized code.

4. Run the code coverage tool. The valid syntax and tool options are shown below.

This step creates a report or exported data as specified. If no other options are specified, the code coverage tool creates a single HTML file (CODE_COVERAGE.HTML) and a sub-directory (CodeCoverage) in the current directory. Open the file in a web browser to view the reports.

NOTE
Windows* only: Unlike the compiler options, which are preceded by forward slash ("/"), the tool options are preceded by a hyphen ("-").

The code coverage tool allows you to name the project and specify paths to specific, necessary files. The following example demonstrates how to name a project and specify .dpi and .spi files to use:

Example: specify .dpi and .spi files

```
codecov -prj myProject -spi pgopti.spi -dpi pgopti.dpi
```

The tool can add a contact name and generate an email link for that contact at the bottom of each HTML page. This provides a way to send an electronic message to the named contact. The following example demonstrates how to add specify a contact and the email links:

Example: add contact information

```
codecov -prj myProject -mname JoeSmith -maddr js@company.com
```

This following example demonstrates how to use the tool to specify the project name, specify the dynamic profile information file, and specify the output format and file name.

Example: export data to text

```
codecov -prj test1 -dpi test1.dpi -txtbcvrg test1_bcvrg.txt
```

Code Coverage Tool Options

Option	Default	Description
`-bcolor`*color*	#FFFF99	Specifies the HTML color name for code in the uncovered blocks.
`-beginblkdsbl`*string*		Specifies the comment that marks the beginning of the code fragment to be ignored by the coverage tool.
`-blockcounts`		When used with `-txtlcov`, reports individual bloc counts for lines that involved multiple blocks.
`-ccolor`*color*	#FFFFFF	Specifies the HTML color name or code of the covered code.
`-comp`*file*		Specifies the file name that contains the list of files being (or not) displayed.
`-counts`		Generates dynamic execution counts.
`-demang`		Demangles both function names and their arguments.
`-dpi`*file*	`pgopti.dpi`	Specifies the file name of the dynamic profile information file (.dpi).
`-endblkdsbl`*string*		Specifies the comment that marks the end of the code fragment to be ignored by the coverage tool.
`-fcolor`*color*	#FFCCCC	Specifies the HTML color name for code of the uncovered functions.
`-help`, `-h`		Prints tool option descriptions.

Option	Default	Description
-icolor*color*	#FFFFFF	Specifies the HTML color name or code of the information lines, such as basic-block markers and dynamic counts.
-include-nonexec		Block details will also be listed for functions that did not execute, when used with –xmlbcvrg[full] or –txtbcvrg[full] options.
-maddr*string*	Nobody	Sets the email address of the web-page owner
-mname*string*	Nobody	Sets the name of the web-page owner.
-nopartial		Treats partially covered code as fully covered code.
-nopmeter		Turns off the progress meter. The meter is enabled by default.
-nounwind		Ignores compiler-generated unwind handlers for exception handling cleanup when computing and displaying basic block coverage.
-onelinedsblstring		Specifies the comment that marks individual lines of code or the whole functions to be ignored by the coverage tool.
-pcolor*color*	#FAFAD2	Specifies the HTML color name or code of the partially covered code.
-prj*string*		Sets the project name.
-ref		Finds the differential coverage with respect to ref_dpi_file.
-showdirnames		Displays the full path name for source files in the HTML report, instead of just the base filename.
-spi*file*	pgopti.spi	Specifies the file name of the static profile information file (.spi).
-srcroot*dir*		Specifies a different top level project directory than was used during compiler instrumentation run to use for relative paths to source files in place of absolute paths.

Option	Default	Description

		NOTE
		In order for the substitution to take place, the sources need to be compiled with one of the following options: `[Q]prof-src-root`, `[Q]prof-src-root-cwd`. This option specifies the base directory that is to be treated as the project root directory.
		An example of use is:
		`C:> ifort -Qprof-gen:srcpos -Qprof-src-root c:\workspaces\orig_project_dir test1.f90 test2.f90`
		`C:> test1.exe`
		`C:> profmerge`
		`C:> cd \workspaces\`
		`C:> mv orig_project_dir new_project_dir`
		`C:> cd new_project_dir\src`
		`C:> codecov -srcroot C:\workspaces\new_project_dir`
		Now, "C:\workspaces\new_project_dir" will be substituted for "c:\workspaces\orig_project_dir" when looking for the source files.
		For use of `[Q]prof-src-root`, `[Q]prof-src-root-cwd` options, refer to prof-src-root/Qprof-src-root, prof-src-root-cwd/Qprof-src-root-cwd

`-txtbcvrg`*file*		Export block-coverage for covered functions as text format. The file parameter must be in the form of a valid file name.
`-txtbcvrgfull`*file*		Export block-coverage for entire application in text and HTML formats. The file parameter must be in the form of a valid file name.
`-txtdcg`*file*		Generates the dynamic call-graph information in text format. The file parameter must be in the form of a valid file name.
`-txtfcvrg`*file*		Export function coverage for covered function in text format. The file parameter must by in the form of a valid file name.
`-txtlcov`*file*		Generates line coverage in text format output files, instead of block coverage in HTML output files.
`-ucolor`*color*	#FFFFFF	Specifies the HTML color name or code of the unknown code.
`-xcolor`*color*	#90EE90	Specifies the HTML color of the code ignored.
`-xmlbcvrg`*file*		Export the block-coverage for the covered function in XML format. The file parameter must by in the form of a valid file name.
`-xmlbcvrgfull`*file*		Export function coverage for entire application in XML format in addition to HTML output. The file parameter must be in the form of a valid file name.

Option	Default	Description
`-xmlfcvrg`*file*		Export function coverage for covered function in XML format. The file parameter must be in the form of a valid file name.

Visually Presenting Code Coverage for an Application

Based on the profile information collected from running the instrumented binaries when testing an application, the Intel® compiler will create HTML-formatted reports using the code coverage tool. These reports indicate portions of the source code that were or were not exercised by the tests. When applied to the profile of the performance workloads, the code coverage information shows how well the training workload covers the application's critical code. High coverage of performance-critical modules is essential to taking full advantage of the profile-guided optimizations.

The code coverage tool can create two levels of coverage:

- Top level (for a group of selected modules)
- Individual module source views

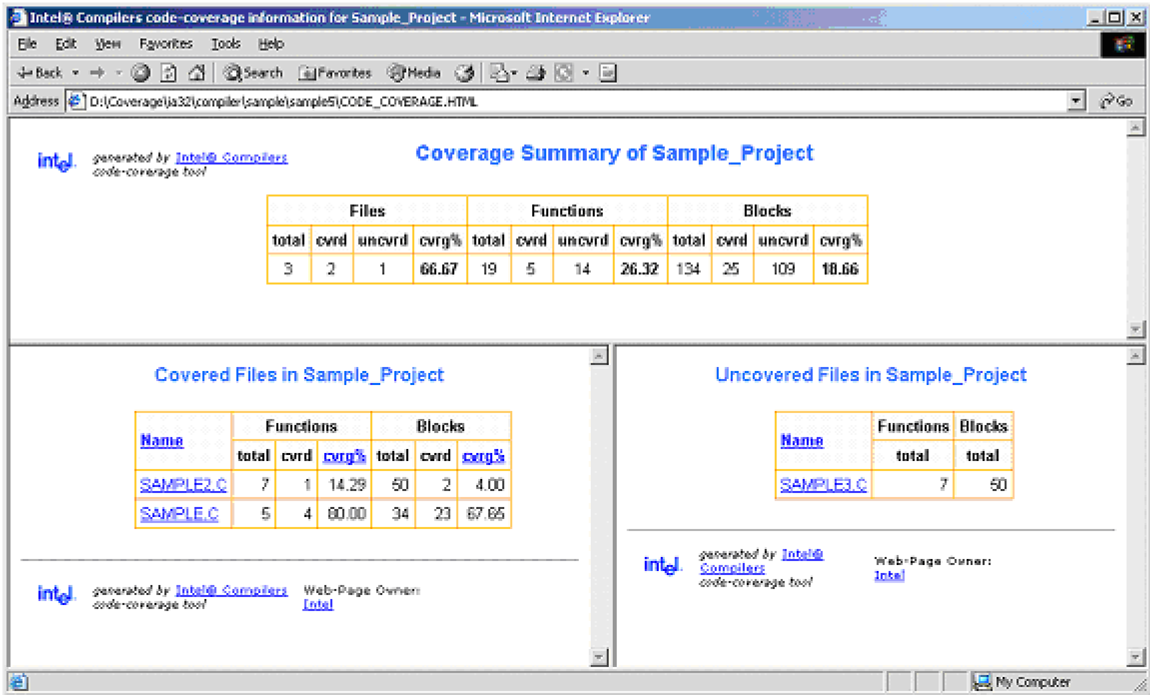
Top-Level Coverage

The top-level coverage reports the overall code coverage of the modules that were selected. The following options are provided:

- Select the modules of interest.
- For the selected modules, the tool generates a list with their coverage information. The information includes the total number of functions and blocks in a module and the portions that were covered.
- By clicking on the title of columns in the reported tables, the lists may be sorted in ascending or descending order based on:
  - Basic-block coverage
  - Function coverage
  - Function name

By default, the code coverage tool generates a single HTML file (CODE_COVERAGE.HTML) and a subdirectory (CodeCoverage) in the current directory. The HTML file defines a frameset to display all of the other generated reports. Open the HTML file in a web-browser. The tool places all other generated report files in a CodeCoverage subdirectory.

If you choose to generate the html-formatted version of the report, you can view coverage source of that particular module directly from a browser. The following figure shows the top-level coverage report.



The coverage tool creates a frame set that allows quick browsing through the code to identify uncovered code. The top frame displays the list of uncovered functions while the bottom frame displays the list of covered functions. For uncovered functions, the total number of basic blocks of each function is also displayed. For covered functions, both the total number of blocks and the number of covered blocks as well as their ratio (that is, the coverage rate) are displayed.

For example, 66.67(4/6) indicates that four out of the six blocks of the corresponding function were covered. The block coverage rate of that function is thus 66.67%. These lists can be sorted based on the coverage rate, number of blocks, or function names. Function names are linked to the position in source view where the function body starts. With one click you can see the least-covered function in the list, and with another click you can see the body of the function. You can scroll down in the source view and browse through the function body.

Individual Module Source View

Within the individual module source views, the tool provides the list of uncovered functions as well as the list of covered functions. The lists are reported in two distinct frames that provide easy navigation of the source code. The lists can be sorted based on:

- Number of blocks within uncovered functions
- Block coverage in the case of covered functions
- Function names

Setting the Coloring Scheme for the Code Coverage

The tool provides a visible coloring distinction of the following coverage categories: covered code, uncovered basic blocks, uncovered functions, partially covered code, and unknown code. The default colors that the tool uses for presenting the coverage information are shown in the tables that follows:

Category	Default	Description
Covered code	#FFFFFF	Indicates code was exercised by the tests. You can override the default color with the `-ccolor` tool option.

Category	Default	Description
Uncovered basic block	#FFFF99	Indicates the basic blocks that were not exercised by any of the tests. However, these blocks were within functions that were executed during the tests. You can override the default color with the `-bcolor` tool option.
Uncovered function	#FFCCCC	Indicates functions that were never called during the tests. You can override the default color with the `-fcolor` tool option.
Partially covered code	#FAFAD2	Indicates that more than one basic block was generated for the code at this position. Some of the blocks were covered and some were not. You can override the default color with the `-pcolor` tool option.
Ignored code	#90EE90	Indicates code that was specifically marked to be ignored. You can override this default color using the `-xcolor` tool option.
Information lines	#FFFFFF	Indicates basic-block markers and dynamic counts. You can override the default color with the `-icolor` tool option.
Unknown	#FFFFFF	Indicates that no code was generated for this source line. Most probably, the source at this position is a comment, a header-file inclusion, or a variable declaration. You can override the default color with the `-ucolor` tool option.

The default colors can be customized to be any valid HTML color name or hexadecimal value using the options mentioned for each coverage category in the table above.

For code coverage colored presentation, the coverage tool uses the following heuristic: source characters are scanned until reaching a position in the source that is indicated by the profile information as the beginning of a basic block. If the profile information for that basic block indicates that a coverage category changes, then the tool changes the color corresponding to the coverage condition of that portion of the code, and the coverage tool inserts the appropriate color change in the HTML-formatted report files.

NOTE
You need to interpret the colors in the context of the code. For example, comment lines that follow a basic block that was never executed would be colored in the same color as the uncovered blocks. Another example is the closing brackets in C/C++ applications.

Dynamic Counters

The coverage tool can be configured to generate the information about the dynamic execution counts. This ability can display the dynamic execution count of each basic block of the application and is useful for both coverage and performance tuning.

The custom configuration requires using the `-counts` option. The counts information is displayed under the code after a "^" sign precisely under the source position where the corresponding basic block begins.

If more than one basic block is generated for the code at a source position (for example, for macros), then the total number of such blocks and the number of the blocks that were executed are also displayed in front of the execution count. For example, line 11 in the code is an `if` statement:

Example

```
11  if ((N == 1).OR. (N == 0))
     ^ 10 (1/2)
12      printf("%d\n", N)
        ^
```

The coverage lines under code lines 11 and 12 contain the following information:

- The `IF` statement in line 11 was executed 10 times.
- Two basic blocks were generated for the `IF` statement in line 11.
- Only one of the two blocks was executed, resulting in the partial coverage color.
- Only seven out of the ten times variable n had a value of 0 or 1.

In certain situations, it may be desirable to consider all the blocks generated for a single source position as one entity. In such cases, it is necessary to assume that all blocks generated for one source position are covered when at least one of the blocks is covered. This assumption can be configured with the `-nopartial` option. When this option is specified, decision coverage is disabled, and the related statistics are adjusted accordingly. The code lines 11 and 12 indicate that the `print` statement in line 12 was covered. However, only one of the conditions in line 11 was ever true. With the `-nopartial` option, the tool treats the partially covered code (like the code on line 11) as covered.

Differential Coverage

Using the code coverage tool, you can compare the profiles from two runs of an application: a reference run, and a new run identifying the code that is covered by the new run but not covered by the reference run. Use this feature to find the portion of the applications code that is not covered by the applications tests but is executed when the application is run by a customer. It can also be used to find the incremental coverage impact of newly added tests to an applications test space.

Generating Reference Data

Create the dynamic profile information for the reference data, which can be used in differential coverage reporting later, by using the `-ref` option. The following command demonstrate a typical command for generating the reference data:

Example: generating reference data

```
codecov -prj Project_Name -dpi customer.dpi -ref appTests.dpi
```

The coverage statistics of a differential-coverage run shows the percentage of the code exercised on a new run but missed in the reference run. In such cases, the tool shows only the modules that included the code that was not covered. Keep this in mind when viewing the coloring scheme in the source views.

The code with the same coverage property (covered or not covered) on both runs is considered covered code. Otherwise, if the new run indicates that the code was executed, while in the reference run the code was not executed, then the code is treated as uncovered. Alternately, if the code is covered in the reference run but not covered in the new run, the differential-coverage source view shows the code as covered.

Running Differential Coverage

To run the code coverage tool for differential coverage, you must have the application sources, the .spi file, and the .dpi file, as described in the code coverage tool Requirements section (above).

Once the required files are available, enter a command similar to the following begin the process of differential coverage analysis:

Example

```
codecov -prj Project_Name -spi pgopti.spi -dpi pgopti.dpi
```

Specify the .dpi and .spi files using the `-spi` and `-dpi` options.

Excluding Code from Coverage Analysis

The code coverage tool allows you to exclude portions of your code from coverage analysis. This ability can be useful during development; for example, certain portions of code might include functions used for debugging only. The test case should not include tests for functionality that will be unavailable in the final application.

Another example of code that can be excluded is code that might be designed to deal with internal errors unlikely to occur in the application. In such cases, lack of a test case is preferred. You may want to ignore infeasible (dead) code in the coverage analysis. The code coverage tool provides several options for marking portions of the code infeasible and ignoring the code at the file level, function level, line level, and arbitrary code boundaries indicated by user-specific comments. The following sections explain how to exclude code at different levels.

Including and Excluding Coverage at the File Level

The code coverage tool provides the ability to selectively include or exclude files for analysis. Create a component file and add the appropriate string values that indicate the file and directory name for code you want included or excluded. Pass the file name as a parameter of the `-comp` option. The following example shows the general command:

Example: specifying a component file

```
codecov -comp file
```

where *file* is the name of a text file containing strings that act as file/directory name masks for including and excluding file-level analysis. For example, assume the following:

- You want to include all files with the string "source" in the file name or directory name.
- You create a component text file named `myComp.txt` with the selective inclusion string "source".

Once you have a component file, enter a command similar to the following:

Example

```
codecov -comp myComp.txt
```

In this example, filenames with string "source" (like source1.c and source2.c) and all files within directories where the directory name contains the string "source" (like source/file1.c and source2\file2.c) are included in the analysis.

To exclude files or directories, add the tilde (~) prefix to the string. You can specify inclusion and exclusion in the same component file. For example, assume you want to analyze all individual files or files in a directory where the file/directory name includes the string "source", and you want to exclude all individual files and files in directories where the file/directory name includes the string "skip". You add content similar to the following to the component file (`myComp.txt`) and pass it to the `-comp` option:

Example: inclusion and exclusion strings in the myComp.txt file

```
source

~skip
```

Entering the `codecov -comp myComp.txt` command with both instructions in the component file, `myComp.txt`, instructs the tool to:

- Include files with filename containing "source" (like source1.c and source2.c)
- Include all files in directories with the directory name containing "source" (like source/file1.c and source2\file2.c)

- Exclude all files with filename containing "skip" (like skipthis1.c and skipthis2.c)
- Exclude all files in directories with the directory name containing "skip" (like skipthese1\debug1.c and skipthese2\debug2.c)

Excluding Coverage at the Line and Function Level

You can mark individual lines for exclusion my passing string values to the `-onelinedsbl` option. For example, assume that you have some code similar to the following:

Sample code

```
printf ("internal error 123 - please report!\n");  // NO_COVER
printf ("internal error 456 - please report!\n");  /* INF IA-32 architecture */
```

If you wanted to exclude all functions marked with the comments NO_COVER or INF IA-32 architecture, you would enter a command similar to the following.

Example

```
codecov -onelinedsbl NO_COVER -onelinedsbl "INF IA-32 architecture"
```

You can specify multiple exclusion strings simultaneously, and you can specify any string values for the markers; however, you must remember the following guidelines when using this option:

- Inline comments must occur at the end of the statement.
- The string must be a part of an inline comment.

An entire function can be excluded from coverage analysis using the same methods. For example, the following function will be ignored from the coverage analysis when you issue example command shown above.

Sample code

```
void dumpInfo (int n)
{      // NO_COVER
...
}
```

Additionally, you can use the code coverage tool to color the infeasible code with any valid HTML color code by combining the `-onelinedsbl` and `-xcolor` options. The following example commands demonstrate the combination:

Example: combining tool options

```
codecov -onelinedsbl INF -xcolor lightgreen

codecov -onelinedsbl INF -xcolor #CCFFCC
```

Excluding Code by Defining Arbitrary Boundaries

The code coverage tool provides the ability to arbitrarily exclude code from coverage analysis. This feature is most useful where the excluded code either occur inside of a function or spans several functions.

Use the `-beginblkdsbl` and `-endblkdsbl` options to mark the beginning and end (respectively) of any arbitrarily defined boundary to exclude code from analysis. Remember the following guidelines when using these options:

- Inline comments must occur at the end of the statement.
- The string must be a part of an inline comment.

For example assume that you have the following code:

Sample code

```
void div (int m, int n) {
if (n == 0)
/* BEGIN_INF */
{ printf (internal error 314 please report\n);
recover (); }
/* END_INF */
else { ... }
}
...
// BINF
Void recover () { ... }
// EINF
```

The following example commands demonstrate how to use the `-beginblkdsbl` option to mark the beginning and the `-endblkdsbl` option to mark the end of code to exclude from the sample shown above.

Example: arbitrary code marker commands

```
codecov -xcolor #ccFFCC -beginblkdsbl BINF -endblkdsbl EINF

codecov -xcolor #ccFFCC -beginblkdsbl "BEGIN_INF" -endblkdsbl "END_INF"
```

Notice that you can combine these options in combination with the `-xcolor` option.

Exporting Coverage Data

The code coverage tool provides specific options to extract coverage data from the dynamic profile information (.dpi files) that result from running instrumented application binaries under various workloads. The tool can export the coverage data in various formats for post-processing and direct loading into databases: the default HTML, text, and XML. You can choose to export data at the function and basic block levels.

There are two basic methods for exporting the data: quick export and combined export. Each method has associated options supported by the tool

- **Quick export:** The first method is to export the data coverage to text- or XML-formatted files without generating the default HTML report. The application sources need not be present for this method. The code coverage tool creates reports and provides statistics only about the portions of the application executed. The resulting analysis and reporting occurs quickly, which makes it practical to apply the coverage tool to the dynamic profile information (the .dpi file) for every test case in a given test space instead of applying the tool to the profile of individual test suites or the merge of all test suites. The `-xmlfcvrg`, `-txtfcvrg`, `-xmlbcvrg` and `-txtbcvrg` options support the first method.
- **Combined export:** The second method is to generate the default HTML and simultaneously export the data to text- and XML-formatted files. This process is slower than first method since the application sources are parsed and reports generated. The `-xmlbcvrgfull` and `-txtbcvrgfull` options support the second method.

These export methods provide the means to quickly extend the code coverage reporting capabilities by supplying consistently formatted output from the code coverage tool. You can extend these by creating additional reporting tools on top of these report files.

Quick Export

The profile of covered functions of an application can be exported quickly using the `-xmlfcvrg`, `-txtfcvrg`, `-xmlbcvrg`, and `-txtbcvrg` options. When using any of these options, specify the output file that will contain the coverage report. For example, enter a command similar to the following to generate a report of covered functions in XML formatted output:

Example: quick export of function data

```
codecov -prj test1 -dpi test1.dpi -xmlfcvrg test1_fcvrg.xml
```

The resulting report will show how many times each function was executed and the total number of blocks of each function, together with the number of covered blocks and the block coverage of each function. The following example shows some of the content of a typical XML report.

XML-formatted report example

```
<PROJECT name = "test1">
   <MODULE name = "D:\SAMPLE.C">
      <FUNCTION name="f0" freq="2">
         <BLOCKS total="6" covered="5" coverage="83.33%"></BLOCKS>
      </FUNCTION>
      ...
   </MODULE>
   <MODULE name = "D:\SAMPLE2.C">
      ...
   </MODULE>
</PROJECT>
```

In the above example, we note that function f0, which is defined in file sample.c, has been executed twice. It has a total number of six basic blocks, five of which are executed, resulting in an 83.33% basic block coverage.

You can also export the data in text format using the `-txtfcvrg` option. The generated text report, using this option, for the above example would be similar to the following example:

Text-formatted report example

```
Covered Functions in File: "D:\SAMPLE.C"
"f0"    2       6       5        83.33
"f1"    1       6       4        66.67
"f2"    1       6       3        50.00
...
```

In the text formatted version of the report, the each line of the report should be read in the following manner:

Column 1	Column 2	Column 3	Column 4	Column 5
Function name	Execution frequency	Line number of the start of the function definition	Column number of the start of the function definition	Percentage of basic-block coverage of the function

Additionally, the tool supports exporting the block level coverage data using the `-xmlbcvrg` option. For example, enter a command similar to the following to generate a report of covered blocks in XML formatted output:

Example: quick export of block data to XML

```
codecov -prj test1 -dpi test1.dpi -xmlbcvrg test1_bcvrg.xml
```

The example command shown above would generate XML-formatted results similar to the following:

XML-formatted report example

```
<PROJECT name = "test1">
  <MODULE name = "D:\SAMPLE.cpp">
    <FUNCTION name="f0" freq="2">
    ...
      <BLOCK line="11" col="2">
        <INSTANCE id="1" freq="1"> </INSTANCE>
      </BLOCK>
      <BLOCK line="12" col="3">
        <INSTANCE id="1" freq="2"> </INSTANCE>
        <INSTANCE id="2" freq="1"> </INSTANCE>
      </BLOCK>
```

In the sample report, notice that one basic block is generated for the code in function f0 at the line 11, column 2 of the file sample.cpp. This particular block has been executed only once. Also notice that there are two basic blocks generated for the code that starts at line 12, column 3 of file. One of these blocks, which has id = 1, has been executed two times, while the other block has been executed only once. A similar report in text format can be generated through the `-txtbcvrg` option.

Combined Exports

The code coverage tool has also the capability of exporting coverage data in the default HTML format while simultaneously generating the text- and XML-formatted reports.

Use the `-xmlbcvrgfull` and `-txtbcvrgfull` options to generate reports in all supported formats in a single run. These options export the basic-block level coverage data while simultaneously generating the HTML reports. These options generate more complete reports since they include analysis on functions that were not executed at all. However, exporting the coverage data using these options requires access to application source files and take much longer to run.

Dynamic Call Graphs

Using the `-txtdcg` option the tool can provide detailed information about the dynamic call graphs in an application. Specify an output file for the dynamic call-graph report. The resulting call graph report contains information about the percentage of static and dynamic calls (direct, indirect, and virtual) at the application, module, and function levels.

Test Prioritization Tool

The test prioritization tool, also known as the tselect tool, enables the profile-guided optimizations on all supported Intel® architectures, on Linux*, Windows*, and macOS operating systems, to select and prioritize tests for an application based on prior execution profiles.

The tool offers a potential of significant time saving in testing and developing large-scale applications where testing is the major bottleneck.

Development often requires changing applications modules. As applications change, developers can have a difficult time retaining the quality of their functional and performance tests so they are current and on-target. The test prioritization tool lets software developers select and prioritize application tests as application profiles change.

The information about the tool is separated into the following sections:

- Features and benefits
- Requirements and syntax
- Usage model
- Tool options
- Running the tool

Features and Benefits

The test prioritization tool provides an effective testing hierarchy based on the code coverage for an application. The following list summarizes the advantages of using the tool:

- Minimizing the number of tests that are required to achieve a given overall coverage for any subset of the application. The tool defines the smallest subset of the application tests that achieve exactly the same code coverage as the entire set of tests.
- Reducing the turn-around time of testing. Instead of spending a long time on finding a possibly large number of failures, the tool enables the users to quickly find a small number of tests that expose the defects associated with the regressions caused by a change set.
- Selecting and prioritizing the tests to achieve certain level of code coverage in a minimal time based on the data of the tests' execution time.

See Understanding Profile-guided Optimization and Profile an Application topics for general information on creating the files needed to run this tool.

Test Prioritization Tool Requirements

The test prioritization tool needs the following items to work:

- The .spi file generated by Intel® compilers when compiling the application for the instrumented binaries with the `-prof-gen=srcpos` (Linux* and macOS) or `/Qprof-gen:srcpos` (Windows*) option.
- The .dpi files generated by the profmerge tool as a result of merging the dynamic profile information .dyn files of each of the application tests. Run the profmerge tool on all .dyn files that are generated for each individual test and name the resulting .dpi in a fashion that uniquely identifies the test.

- User-generated file containing the list of tests to be prioritized. For successful instrumented code run, you should:

- Name each test .dpi file so the file names uniquely identify each test.
- Create a .dpi list file, which is a text file that contains the names of all .dpi test files.

  Each line of the .dpi list file should include one, and only one .dpi file name. The name can optionally be followed by the duration of the execution time for a corresponding test in the dd:hh:mm:ss format.

  For example: `Test1.dpi 00:00:60:35` states that Test1 lasted 0 days, 0 hours, 60 minutes and 35 seconds.

  The execution time is optional. However, if it is not provided, then the tool will not prioritize the test for minimizing execution time. It will prioritize to minimize the number of tests only.

> **Caution**
> The profmerge tool merges all .dyn files that exist in the given directory. Make sure unrelated .dyn files, which may remain from unrelated runs, are not present. Otherwise, the profile information will be skewed with invalid profile data, which can result in misleading coverage information and adverse performance of the optimized code. The tool uses the following general syntax:

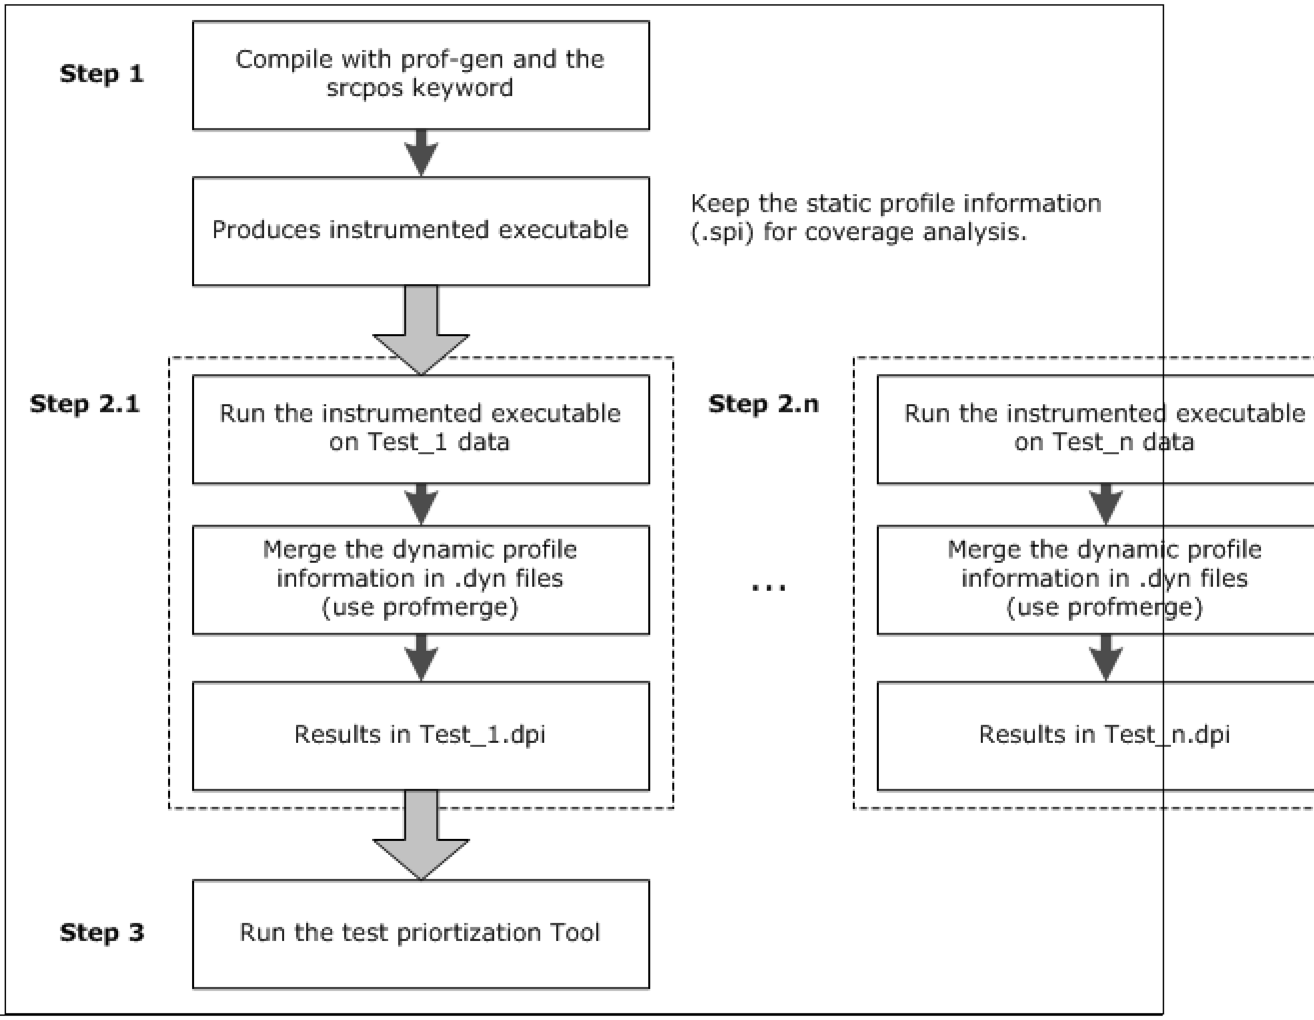
Tool Syntax
`tselect -dpi_list`*file*

`-dpi_list` is a required tool option that sets the path to the list file containing the list of the all .dpi files. All other tool commands are optional.

> **NOTE**
> Windows* only: Unlike the compiler options, which are preceded by forward slash ("/"), the tool options are preceded by a hyphen ("-").

Usage Model

The following figure illustrates a typical test prioritization tool usage model.



Test Prioritization Tool Options

The tool uses the options that are listed in the following table:

Option	Description
`-help`	Prints tool option descriptions.
`-dpi_list`*file*	Required. Specifies the name of the file that contains the names of the dynamic profile information (`.dpi`) files. Each line of the file must contain only one .dpi file name, which can be followed by its execution time (optional). The name must uniquely identify the test.
`-spi`*file*	Specifies the file name of the static profile information file (.SPI). Default is `pgopti.spi`
`-o`*file*	Specifies the file name of the output report file.

Option	Description
`-comp`*file*	Specifies the file name that contains the list of files of interest.
`-cutoff`*value*	Instructs the tool to terminate when the cumulative block coverage reaches a preset percentage, as specified by `value`, of pre-computed total coverage. `value` must be greater than 0.0 (for example, 99.00) but not greater than 100. `value` can be set to 100.
`-nototal`	Instructs the tool to ignore the pre-compute total coverage process.
`-mintime`	Instructs the tool to minimize testing execution time. The execution time of each test must be provided on the same line of `dpi_list` file, after the test name in dd:hh:mm:ss format.
`-srcbasedir`*dir*	Specifies a different top-level project directory than was used during compiler instrumentation run with the `prof-src-root` compiler option to support relative paths to source files in place of absolute paths.
`-verbose`	Instructs the tool to generate more logging information about program progress.

Running the Tool

The following steps demonstrate one simple example for running the tool on IA-32 architectures.

1. Specify the directory by entering a command similar to the following:

   Example

   ```
   set PROF_DIR=c:\myApp\prof-dir
   ```
2. Compile the program and generate instrumented binary by issuing commands similar to the following:

Operating System	Command
Linux and macOS	`icpc -prof-gen=srcpos myApp.cpp`
Windows	`icl /Qprof-gen:srcpos myApp.cpp`

   The commands shown above compile the program and generate instrumented binary `myApp`, as well as the corresponding static profile information `pgopti.spi`.
3. Confirm that unrelated `.dyn` files are not present by issuing a command similar to the following:

   Example

   ```
   rm prof-dir \*.dyn
   ```
4. Run the instrumented files by issuing a command similar to the following:

Example

```
myApp < data1
```

The command runs the instrumented application and generates one or more new dynamic profile information files that have an extension `.dyn` in the directory specified by the `-prof-dir` step above.

5. Merge all `.dyn` file into a single file by issuing a command similar to the following:

Example

```
profmerge -prof_dpi Test1.dpi
```

The profmerge tool merges all the .dyn files into one file (`Test1.dpi`) that represents the total profile information of the application on Test1.

6. Confirm again there are no unrelated .dyn files present a second time by issuing a command similar to the following:

Example

```
rm prof-dir \*.dyn
```

7. Run the instrumented application, and generate one or more new dynamic profile information files that have an extension .dyn in the directory specified in the `prof-dir` step above by issuing a command similar to the following:

Example

```
myApp < data2
```

8. Merge all .dyn files into a single file by issuing a command similar to the following:

Example

```
profmerge -prof_dpi Test2.dpi
```

At this step, the profmerge tool merges all the .dyn files into one file (`Test2.dpi`) that represents the total profile information of the application on Test2.

9. Confirm that there are no unrelated .dyn files present for the final time by issuing a command similar to the following:

Example

```
rm prof-dir \*.dyn
```

10. Run the instrumented application and generate one or more new dynamic profile information files that have an extension .dyn in the directory specified by `-prof-dir` by issuing a command similar to the following:

Example

```
myApp < data3
```

11. Merge all .dyn file into a single file, by issuing a command similar to the following:

Example

```
profmerge -prof_dpi Test3.dpi
```

At this step, the profmerge tool merges all the .dyn files into one file (`Test3.dpi`) that represents the total profile information of the application on Test3.

12. Create a file named `tests_list` with three lines. The first line contains `Test1.dpi`, the second line contains `Test2.dpi`, and the third line contains `Test3.dpi`.

Tool Usage Examples

When these items are available, the test prioritization tool may be launched from the command line in the `prof-dir` directory as described in the following examples.

Example 1: Minimizing the Number of Tests

The following example describes how minimize the number of test runs.

Example Syntax

```
tselect -dpi_list tests_list -spi pgopti.spi
```

where the `-spi` option specifies the path to the .spi file.

The following sample output shows typical results.

Sample Output

```
Total number of tests   =  3
Total block coverage    ~  52.17
Total function coverage ~  50.00
 num  %RatCvrg  %BlkCvrg  %FncCvrg  Test Name @ Options
 ---  --------  --------  --------  -------------------
   1   87.50     45.65     37.50    Test3.dpi
   2   100.50    52.17     50.00    Test2.dpi
```

In this example, the results provide the following information:

- By running all three tests, you achieve 52.17% block coverage and 50.00% function coverage.
- Test3 alonecovers 45.65% of the basic blocks of the application, which is 87.50% of the total block coverage that can be achieved from all three tests.
- By adding Test2, you achieve a cumulative block coverage of 52.17% or 100% of the total block coverage of Test1, Test2, and Test3.
- Elimination of Test1 has no negative impact on the total block coverage.

Example 2: Minimizing Execution Time

Assume you have the following execution time of each test in the `tests_list` file:

Sample Output

```
Test1.dpi 00:00:60:35
Test2.dpi 00:00:10:15
Test3.dpi 00:00:30:45
```

The following command minimizes the execution time by passing the `-mintime` option:

Sample Syntax

```
tselect -dpi_list tests_list -spi pgopti.spi -mintime
```

The following sample output shows possible results:

Sample Output

```
Total number of tests   =  3
Total block coverage    ~  52.17
Total function coverage ~  50.00
Total execution time    =  1:41:35
 num  elaspedTime  %RatCvrg  %BlkCvrg  %FncCvrg  Test Name @ Options
 ---  -----------  --------  --------  --------  -------------------
   1   10:15         75.00     39.13     25.00    Test2.dpi
   2   41:00         100.00    52.17     50.00    Test3.dpi
```

In this case, the results indicate that running all tests sequentially would require one hour, 45 minutes, and 35 seconds, while the selected tests would achieve the same total block coverage in only 41 minutes.

The order of tests when based on minimizing time (first Test2, then Test3) may be different than when prioritization is done based on minimizing the number of tests. See Example 1 shown above: first Test3, then Test2. In Example 2, Test2 is the test that gives the highest coverage per execution time, so Test2 is picked as the first test to run.

Using Other Options

The `-cutoff` enables the tool to exit when it reaches a given level of basic block coverage. The following example demonstrates how to use the option:

Example

```
tselect -dpi_list tests_list -spi pgopti.spi -cutoff 85.00
```

If the tool is run with the cutoff value of 85.00, as in the above example, only Test3 will be selected, as it achieves 45.65% block coverage, which corresponds to 87.50% of the total block coverage that is reached from all three tests.

The tool does an initial merging of all the profile information to figure out the total coverage that is obtained by running all the tests. The `-cutoff` enables you to skip this step. In such a case, only the absolute coverage information will be reported, as the overall coverage remains unknown.

Profmerge and Proforder Tools

Profmerge Tool

Use the profmerge tool to merge dynamic profile information (`.dyn`) files and any specified summary files (`.dpi`). The compiler executes profmerge automatically during the feedback compilation phase when you specify the `[Q]prof-use` option.

The command-line usage for profmerge is as follows:

Syntax

```
profmerge [-prof_dir dir_name]
```

The tool merges all `.dyn` files in the current directory, or the directory specified by `-prof_dir`, and produces a summary file: `pgopti.dpi`.

NOTE
The spelling of tools options may differ slightly from compiler options. Tools options use an underscore (for example -prof_dir) instead of the hyphen used by compiler options (for example `[Q]prof-dir`) to join words. Also, on Windows* systems, the tool options are preceded by a hyphen ("-") unlike Windows* compiler options, which are preceded by a forward slash ("/").

You can use profmerge tool to merge .dyn files into a `.dpi` file without recompiling the application. You can run the instrumented executable file on multiple systems to generate `.dyn` files, and optionally use profmerge with the `-prof_dpi` option to name each summary `.dpi` file created from the multiple `.dyn` files.

Because the profmerge tool merges all the `.dyn` files that exist in the given directory, confirm that unrelated `.dyn` files are not present; otherwise, profile information will be based on invalid profile data, which can negatively impact the performance of optimized code.

Profmerge Options

The profmerge tool supports the following options:

Tool Option	Description
`-dump`	Displays profile information.
`-help`	Lists supported options.
`-nologo`	Disables version information. This option is supported on Windows* only.
`-exclude_files`*`files`*	Excludes functions from the profile if the function comes from one of the listed files. The list items must be separated by a comma (","); you can use a period (".") as a wild card character in function names.
`-exclude_funcs`*`functions`*	Excludes functions from the profile. The list items must be separated by a comma (","); you can use a period (".") as a wild card character in function names.
`-prof_dir`*`dir`*	Specifies the directory from which to read `.dyn` and `.dpi` files, and write the `.dpi` file. Alternatively, you can set the environment variable`PROF_DIR`.
`-prof_dpi`*`file`*	Specifies the name of the `.dpi` file being generated.
`-prof_file`*`file`*	Merges information from file matching: dpi_file_and_dyn_tag.
`-src_old`*`dir`*`-src_new`*`dir`*	Changes the directory path stored within the `.dpi` file.
`-no_src_dir`	Uses only the file name and not the directory name when reading dyn/dpi records. If you specify `-no_src_dir`, the directory name of the source file

Tool Option	Description
	will be ignored when deciding which profile data records correspond to a specific application routine, and the `-src-root` option is ignored.
`-src-root`*`dir`*	Specifies a directory path prefix for the root directory where the user's application files are stored. This option is ignored if you specify `-no_src_dir`.
`-a`*`file1.dpi`*`...`*`fileN.dpi`*	Specifies and merges available `.dpi` files.
`-verbose`	Instructs the tool to display full information during merge.
`-weighted`	Instructs the tool to apply an equal weighting (regardless of execution times) to the `.dyn` file values to normalize the data counts. This keyword is useful when the execution runs have different time durations and you want them to be treated equally.
`-gen_weight_spec` *file*	Instructs the tool to generate a text file containing a list of the `.dyn` and `.dpi` file that were merged with default weight=1/run_count. The text file is created in the directory specified by the `prof_dir` option.
`-weight_spec` *weight_spec.txt*	Instructs the profmerge tool to generate and use the text file, *weight_spec.txt,* listing individual `.dyn`/`.dpi` files or directory names along with weight values for them. When the `-weight_spec` option is used: • A new `.dpi` file is always created • Only files called out by the specification file are merged • `.dyn` timestamps are ignored and merge always takes place The `prof_dir` option controls where the input/ output *weight_spec.txt* is located, and the destination of the .dpi file. The `-weight_spec` option overrides: • Any values of `-a` option • Any computation from using `-weighted` option

Weighting the Runs

Using the `-weight_spec` option results in a new `.dpi` file. Only the files listed in the text file are merged. No files in the current directory are used unless they are included in the text file.

Relocating source files using profmerge

The Intel® C++ Compiler uses the full path to the source file for each routine to look up the profile summary information associated with that routine. By default, this prevents you from:

- Using the profile summary file (`.dpi`) if you move your application sources.
- Sharing the profile summary file with another user who is building identical application sources that are located in a different directory.

You can disable the use of directory names when reading `.dyn`/`.dpi` file records by specifying the `profmerge` option `-no_scr_dir`. This `profmerge` option is the same as the compiler option `-no-prof-src-dir` (Linux* and macOS) and `/Qprof-src-dir-` (Windows*).

To enable the movement of application sources, as well as the sharing of profile summary files, you can use the `profmerge` option `-src-root` to specify a directory path prefix for the root directory where the application files are stored. Alternatively, you can specify the option pair `-src_old-src_new` to modify the data in an existing summary dpi file. For example:

Example: relocation command syntax

```
profmerge -prof_dir <dir1> -src_old <dir2> -src_new <dir3>
```

where *<dir1>* is the full path to dynamic information file (.dpi), *<dir2>* is the old full path to source files, and *<dir3>* is the new full path to source files. The example command (above) reads the `pgopti.dpi` file, in the location specified in *<dir1>*. For each function represented in the `pgopti.dpi` file, whose source path begins with the *<dir2>* prefix, profmerge replaces that prefix with *<dir3>*. The `pgopti.dpi` file is updated with the new source path information.

You can run profmerge more than once on a given `pgopti.dpi` file. For example, you may need to do this if the source files are located in multiple directories:

Operating System	Command Examples
Linux* and macOS	`profmerge -prof_dir -src_old /src/prog_1 -src_new /src/prog_2` `profmerge -prof_dir -src_old /proj_1 -src_new /proj_2`
Windows*	`profmerge -src_old "c:/program files" -src_new "e:/program files"` `profmerge -src_old c:/proj/application -src_new d:/app`

In the values specified for `-src_old` and `-src_new`, uppercase and lowercase characters are treated as identical in Windows. Likewise, forward slash (`/`) and backward slash (`\`) characters are treated as identical.

NOTE
Because the source relocation feature of profmerge modifies the `pgopti.dpi` file, consider making a backup copy of the file before performing the source relocation.

Proforder Tool

The proforder tool is used as part of the feedback compilation phase, to improve program performance. Use proforder to generate a function order list for use with the `/ORDER` linker option in Windows. The tool uses the following syntax:

Syntax

```
proforder [-prof_dir dir] [-o file]
```

where *dir* is the directory containing the profile files (`.dpi` and `.spi`), and *file* is the optional name of the function order list file. The default name is `proford.txt` .

NOTE
The spelling of tools options may differ slightly from compiler options. Tools options use an underscore (for example `-prof_dir`) instead of the hyphen used by compiler options (for example `[Q]prof-dir`) to join words. Also, on Windows* systems, the tool options are preceded by a hyphen ("-") unlike Windows* compiler options, which are preceded by a forward slash ("/").

Proforder Options

The proforder tool supports the following options:

Tool Option	Default	Description
`-help`		Lists supported options.
`-nologo`		Disables version information. This option is supported on Windows* only.
`-omit_static`		Instructs the tool to omit static functions from function ordering.
`-prof_dir`*dir*		Specifies the directory where the `.spi` and `.dpi` file reside.
`-prof_dpi`*file*		Specifies the name of the `.dpi` file.
`-prof_file`*string*		Selects the `.dpi` and `.spi` files that include the substring value in the file name matching the values passed as string.
`-prof_spi`*file*		Specifies the name of the `.spi` file.
`-o`*file*	`proford.txt`	Specifies an alternate name for the output file.

Using Function Order Lists, Function Grouping, Function Ordering, and Data Ordering Optimizations

Instead of doing a full multi-file interprocedural build of your application by using the compiler option `[Q]ipo`, you can obtain some of the benefits by having the compiler and linker work together to make global decisions about where to place the functions and data in your application. These optimizations are not supported on macOS systems.

The following table lists each optimization, the type of functions or global data it applies to, and the operating systems and architectures that it is supported on.

Optimization	Type of Function or Data	Supported OS and Architectures
Function Order Lists: Specifies the order in which the linker should link the non-static routines (functions) of your program. This optimization can improve application performance	`extern`functions procedures and library functions only (not static functions).	Windows: all Intel architectures Linux: not supported

Optimization	Type of Function or Data	Supported OS and Architectures
by improving code locality and reduce paging. Also see Comparison of Function Order Lists and IPO Code Layout. **Function Grouping**: Specifies that the linker should place the extern and static routines (functions) of your program into hot or cold program sections. This optimization can improve application performance by improving code locality and reduce paging. **NOTE** This option will cause functions to be placed into the linker sections named ".text.hot" and ".text.unlikely." If you are using a custom linker script, you will need to specify memory placement for these sections.	`extern`functions and static functions only (not library functions).	Linux: IA-32 and Intel 64 architectures Windows: not supported
Function Ordering: Enables ordering of static and extern routines using profile information. Specifies the order in which the linker should link the routines (functions) of your program. This optimization can improve application performance by improving code locality and reduce paging.	`extern`functions and static functions only (not library functions)	Linux and Windows: all Intel architectures
Data Ordering: Enables ordering of static global data items based on profiling information. Specifies the order in which the linker should link global data of your program. This optimization can improve application performance by improving the locality of static global data, reduce paging of large data sets, and improve data cache use.	Static global data only	Linux and Windows: all Intel architectures

You can only use one of the function-related ordering optimizations listed above on each application. However, you can use the Data Ordering optimization with any one of the function-related ordering optimizations listed above, such as Data Ordering with Function Ordering, or Data Ordering with Function Grouping. In this case, specify the `prof-gen` option keyword `globdata` (needed for Data Ordering) instead of `srcpos` (needed for function-related ordering).

The following sections show the commands needed to implement each of these optimizations: function order list, function grouping, function ordering, and data ordering. For all of these optimizations, omit the `[Q]ipo` or equivalent compiler option.

Generating a Function Order List (Windows)

This section provides an example of the process for generating a function order list. Assume you have a C++ program that consists of the following files: `file1.cpp` and `file2.cpp`. Additionally, assume you have created a directory for the profile data files called `c:\profdata`. You would enter commands similar to the following to generate and use a function order list for your Windows application.

1. Compile your program using the `/Qprof-gen:srcpos` option. Use the `/Qprof-dir` option to specify the directory location of the profile files. This step creates an instrumented executable.

Example commands

```
icl /Femyprog /Qprof-gen=srcpos /Qprof-dir c:\profdata file1.cpp file2.cpp
```

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a `.dyn` file each time it is executed.

Example commands

```
myprog.exe
```

3. Before this step, copy all .dyn and .dpi files into the same directory. Merge the data from one or more runs of the instrumented program by using the profmerge tool to produce the `pgopti.dpi` file. Use the `/prof_dir` option to specify the directory location of the .dyn files.

Example commands

```
profmerge /prof_dir c:\profdata
```

4. Generate the function order list using the proforder tool. By default, the function order list is produced in the file `proford.txt`.

Example commands

```
proforder /prof_dir c:\profdata /o myprog.txt
```

5. Compile the application with the generated profile feedback by specifying the `ORDER` option to the linker. Use the `/Qprof-dir` option to specify the directory location of the profile files.

Example commands

```
icl /Femyprog /Qprof-use /Qprof-dir c:\profdata file1.cpp file2.cpp /link -
ORDER:@myprog.txt
```

Using Function Grouping (Linux)

This section provides a general example of the process for using the function grouping optimization. Assume you have a C++ program that consists of the following files: `file1.cpp` and `file2.cpp`. Additionally, assume you have created a directory for the profile data files called `profdata`. You would enter commands similar to the following to use a function grouping for your Linux application.

1. Compile your program using the `-prof-gen` option. Use the `-prof-dir` option to specify the directory location of the profile files. This step creates an instrumented executable.

Example commands
`icc -o myprog -prof-gen -prof-dir ./profdata file1.cpp file2.cpp`

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a `.dyn` file each time it is executed.

Example commands
`./myprog`

3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tools to produce the `pgopti.dpi` file.
4. Compile the application with the generated profile feedback by specifying the `-prof-func-group` option to request the function grouping as well as the `-prof-use` option to request feedback compilation. Again, use the `-prof-dir` option to specify the location of the profile files.

Example commands
`icl /Femyprog file1.cpp file2.cpp -prof-func-group -prof-use -prof-dir ./profdata`

NOTE On Linux, the –prof-func-group option is on by default when –prof-use is selected.

Finer grain control over the number of functions placed into the hot region can be controlled with the `-prof-hotness-threshold` compiler option, see the command line reference for more details.

Using Function Ordering

This section provides an example of the process for using the function ordering optimization. Assume you have a C++ program that consists of the following files: `file1.cpp` and `file2.cpp`, and that you have created a directory for the profile data files called `c:\profdata` (on Windows) or `./profdata` (on Linux). You would enter commands similar to the following to generate and use function ordering for your application.

1. Compile your program using the `-prof-gen=srcpos` (Linux) or `/Qprof-gen:srcpos` (Windows) option. Use the `[Q]prof-dir` option to specify the directory location of the profile files. This step creates an instrumented executable.

Operating System	Example commands
Linux	`icc -o myprog -prof-gen=srcpos -prof-dir ./profdata file1.cpp file2.cpp`
Windows	`icl /Femyprog /Qprof-gen:srcpos /Qprof-dir c:\profdata file1.cpp file2.cpp`

2. Run the instrumented program with one or more sets of input data. Change your directory to the directory where the executables are located. The program produces a `.dyn` file each time it is executed.

Operating System	Example commands
Linux	`./myprog`
Windows	`myprog.exe`

3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tools to produce the `pgopti.dpi` file.
4. Compile the application with the generated profile feedback by specifying the `[Q]prof-func-order` option to request the function ordering, as well as the `[Q]prof-use` option to request feedback compilation. Again, use the `[Q]prof-dir` option to specify the location of the profile files.

Operating System	Example commands
Linux	`icpc -o myprog -prof-dir ./profdata file1.cpp file2.cpp -prof-func-order-prof-use`
Windows	`icl /Femyprog /Qprof-dir c:\profdata file1.cpp file2.cpp /Qprof-func-order /Qprof-use`

Using Data Ordering

This section provides an example of the process for using the data order optimization. Assume you have a C ++ program that consists of the following files: `file1.cpp` and `file2.cpp`, and that you have created a directory for the profile data files called `c:\profdata` (on Windows) or `./profdata` (on Linux). You would enter commands similar to the following to use data ordering for your application.

1. Compile your program using the `-prof-gen=globdata` (Linux) or `/Qprof-gen:globdata` (Windows) option. Use the `-prof-dir` (Linux) or `/Qprof-dir` (Windows) option to specify the directory location of the profile files. This step creates an instrumented executable.

Operating System	Example commands
Linux	`icc -o myprog -prof-gen=globdata -prof-dir ./profdata file1.cpp file2.cpp`
Windows	`icl /Femyprog /Qprof-gen=globdata /Qprof-dir c:\profdata file1.cpp file2.cpp`

2. Run the instrumented program with one or more sets of input data. If you specified a location other than the current directory, change your directory to the directory where the executables are located. The program produces a `.dyn` file each time it is executed.

Operating System	Example commands
Linux	`./myprog`
Windows	`myprog.exe`

3. Copy all .dyn and .dpi files into the same directory. If needed, you can merge the data from one or more runs of the instrumented program by using the profmerge tools to produce the `pgopti.dpi` file.
4. Compile the application with the generated profile feedback by specifying the `[Q]prof-data-order` option to request the data ordering as well as the `[Q]prof-use` option to request feedback compilation. Again, use the `[Q]prof-dir` option to specify the location of the profile files.

Operating System	Example commands
Linux	`icpc -o myprog -prof-dir ./profdata file1.cpp file2.cpp -prof-data-order-prof-use`

Operating System	Example commands
Windows	`icl /Femyprog /Qprof-dir c:\profdata file1.cpp file2.cpp /Qprof-data-order/Qprof-use`

Comparison of Function Order Lists and IPO Code Layout

The Intel® compiler provides two methods of optimizing the layout of functions in the executable:

- Using a function order list
- Using the `/Qipo` (Windows) compiler option

Each method has advantages. A function order list, created with proforder, lets you optimize the layout of non-static functions (external and library functions whose names are exposed to the linker).

The linker cannot directly affect the layout order for static functions because the names of these functions are not available in the object files.

The compiler cannot affect the layout order for functions it does not compile, such as library functions. The function layout optimization is performed automatically when IPO is active.

Alternately, using the `/Qipo` (Windows) option allows you to optimize the layout of all `static` or `extern` functions compiled with the Intel® C++ Compiler. The compiler cannot affect the layout order for functions it does not compile, such as library functions. The function layout optimization is performed automatically when IPO is active.

Function Order List Effects

Function Type	IPO Code Layout	Function Ordering with proforder
Static	X	No effect
Extern	X	X
Library	No effect	X

Function Order List Usage Guidelines (Windows*)

Use the following guidelines to create a function order list:

- The order list only affects the order of non-static functions.
- You must compile with `/Gy` to enable function-level linking. (This option is active if you specify either option `/O1` or `/O2`.)

Compiler Option Mapping Tool

The Intel compiler's Option Mapping Tool provides an easy method to derive equivalent options between Windows* and Linux*. If you are a Windows-based application developer who is developing an application for Linux, you may want to know, for example, the Linux equivalent for the `/Oy-` option. Likewise, the Option Mapping Tool provides Windows equivalents for Intel compiler options supported on Linux.

NOTE
The Option Mapping Tool is not supported on macOS.

Using the Compiler Option Mapping Tool

You can start the Option Mapping Tool from the command line by:

- invoking the compiler and using the `[Q]map-opts` option
- executing the tool directly

> **NOTE**
> Compiler options are mapped to their equivalent on the architecture you are using.

Calling the Option Mapping Tool with the Compiler

If you use the compiler to execute the Option Mapping Tool, the following syntax applies:

```
<compiler command> <map-opts option> <compiler option(s)>
```

Example: Finding the Linux equivalent for `/Oy-`

```
icl /Qmap-opts /Oy-
Intel(R) Compiler option mapping tool
mapping Windows options to Linux for C++
'-Qmap-opts' Windows option maps to
  --> '-map-opts' option on Linux
  --> '-map_opts' option on Linux
'-Oy-' Windows option maps to
  --> '-fomit-frame-pointer-' option on Linux
  --> '-fno-omit-frame-pointer' option on Linux
  --> '-fp' option on Linux
```

Example: Finding the Windows equivalent for `-fp`

```
icpc -map-opts -fp
Intel(R) Compiler option mapping tool
mapping Linux options to Windows for C++
'-map-opts' Linux option maps to
  --> '-Qmap-opts' option on Windows
  --> '-Qmap_opts' option on Windows
'-fp' Linux option maps to
  --> '-Oy-' option on Windows
```

Output from the Option Mapping Tool also includes:

- option mapping information (not shown here) for options included in the compiler configuration file
- alternate forms of the option that are supported but may not be documented

When you call the Option Mapping Tool with the compiler, your source file is not compiled.

Calling the Option Mapping Tool Directly

Use the following syntax to execute the Option Mapping Tool directly from a command line environment where the full path to the `map_opts` executable is known (compiler `bin` directory):

```
map_opts [-nologo] -t<target OS> -l<language> -opts <compiler option(s)>
```

where values for:

- `<target OS> = {l|linux|w|windows}`
- `<language> = {f|fortran|c}`

Example: Finding the Linux equivalent for `/Oy-`

```
map_opts -tl -lc -opts /Oy-
Intel(R) Compiler option mapping tool
mapping Windows options to Linux for C++
'-Oy-' Windows option maps to
```

```
  --> '-fomit-frame-pointer-' option on Linux
  --> '-fno-omit-frame-pointer' option on Linux
  --> '-fp' option on Linux
```

Example: Finding the Windows equivalent for `-fp`

```
map_opts -tw -lc -opts -fp
Intel(R) Compiler option mapping tool
mapping Linux options to Windows for C++
'-fp' Linux option maps to
  --> '-Oy-' option on Windows
```

Part VI

Compatibility and Portability

This section contains information about conformance to language standards, language compatibility, and portability.

Conformance to the C/C++ Standards

The Intel® C++ Compiler conforms to the following ANSI/ISO standards:

- **C++** ISO/IEC 14882:1998
- **C** ISO/IEC 9899:1990

provides conformance to the ANSI/ISO standard for C language compilation (ISO/IEC 9899:1990). This standard requires that conforming C compilers accept minimum translation limits. This compiler exceeds all of the ANSI/ISO requirements for minimum translation limits.

C++ Support

The Intel® C++ Compiler supports many features in C++11. For a list of support features, see *C++ Features Supported by Intel® C++ compiler* at https://software.intel.com/content/www/us/en/develop/articles/c0x-features-supported-by-intel-c-compiler.html.

Template Instatiation

The Intel® C++ Compiler supports `extern` template, which lets you specify that a template in a specific translation unit will not be instantiated because it will be instantiated in a different translation unit or different library. The compiler now includes additional support for:

- **inline template** – instantiates the compiler support data for the class (example: *vtable*) for a class without instantiating its members.
- **static template** – instantiates the static data members of the template, but not the virtual tables or member functions.

You can now use the following options to gain more control over the point of template instantiation:

Option	Description
`-fno-implicit-templates`	Never emit code for non-inline templates which are instantiated implicitly (i.e. by use). only emit code for explicit instantiations.
`-fno-implicit-inline-templates`	Do not emit code for implicit instantiations of inline templates either. The default is to handle inlines differently so that compilations, with and without optimization, will need the same set of explicit instantiations.

C99 Support

The following C99 features are supported in this version of the Intel® C++ Compiler:

- restricted pointers (`restrict` keyword).
- variable-length Arrays
- flexible array members
- complex number support (`_Complex` keyword)
- hexadecimal floating-point constants
- compound literals
- designated initializers
- mixed declarations and code
- macros with a variable number of arguments
- inline functions (`inline` keyword)
- boolean type (`_Bool` keyword)

These `long double` (128-bit representations) feature is not supported:

`-fno-implicit-templates` compiler option

`-fno-implicit-inline-templates` compiler option

GCC Compatibility and Interoperability

GCC Compatibility

The Intel® C++ Compiler Classic is compatible with most versions of the GNU Compiler Collection (GCC). The release notes contains a list of compatible versions.

C language object files created with the compiler are binary compatible with the GCC and C/C++ language library. You can use the Intel® C++ Compiler Classic or the GCC compiler to pass object files to the linker.To pass IPO mock object files or libraries of IPO mock object files produced by theIntel® C++ Compiler Classic to the linker, use the linking tools provided with the compiler. Specifically:

Use `icc`, `icpc`, `xild`, and `xiar`.

NOTE When using an Intel software development product that includes a compiler with a Clang front-end, you can also use `icl`.

Link-time optimization using the `-ffat-lto-objects` compiler option is provided for GCC compatibility. This implies that `ld` and `ar` can be used to link and archive object files, but by doing so you will lose cross-file optimizations. You can use the `-fno-fat-lto-objects` compiler option when linking using IPO mock object files, provided that you link the IPO mock object files with `xild` and archive them with `xiar`.

The Intel® C++ Compiler Classic supports many of the language extensions provided by the GNU compilers.

Statement expressions are supported, except that the following are prohibited inside them:

- Dynamically-initialized local static variables
- Local non-POD class definitions
- Try/catch
- Variable length arrays

Branching out of a statement expression and statement expressions in constructor initializers are not allowed. Variable-length arrays are no longer allowed in statement expressions.

The Intel® C++ Compiler Classic supports GCC-style inline ASM if the assembler code uses AT&T* System V/386 syntax.

GCC Interoperability

C++ compilers are interoperable if they can link object files and libraries generated by one compiler with object files and libraries generated by the second compiler, and the resulting executable runs successfully. The Intel® C++ Compiler Classic is highly compatible with the GNU compilers.

The Intel® C++ Compiler Classic and GCC support the following predefined macros:

- `__GNUC__`
- `__GNUG__`
- `__GNUC_MINOR__`
- `__GNUC_PATCHLEVEL__`

> **Caution** Not defining these macros results in different paths through system header files. These alternate paths may be poorly tested or otherwise incompatible.

How the Compiler Uses GCC

The Intel® C++ Compiler Classic uses the GNU tools on the system, such as the GNU header files, including `stdio.h`, and the GNU linker and libraries. So the compiler has to be compatible with the version of GCC or G++* you have on your system. For example, if you have GCC version 4.6 on your system, `icc` behaves like GCC 4.6, with the compatible features and behaviors.

By default, the compiler determines which version of GCC or G++ you have installed from the `PATH` environment variable.

If you want use a version of GCC or G++ other than the default version on your system, you need to use the `--gcc-toolchain` compiler option to specify the location of the base toolchain. For example:

- You want to build something that cannot be compiled by the default version of the system compiler, so you need to use a legacy version for compatibility, such as if you want to use third party libraries that are not compatible with the default version of the system compiler.
- You want to use a later version of GCC or G++ than the default system compiler.

The Intel® C++ Compiler Classic driver uses the default version of GCC/G++, or the version you specify, to extract the location of the headers and libraries.

Compatibility with Open Source Tools

The Intel® C++ Compiler Classic includes improved support for the following open source tools:

- **GNU Libtool**: A script that allows package developers to provide generic shared library support.
- **Valgrind**: A flexible system for debugging and profiling executables running on x86 processors.
- **GNU Automake**: A tool for automatically generating `Makefile.ins` from files called `Makefile.am`.

See Also

ffat-lto-objects

Microsoft Compatibility

The Intel® C++ Compiler Classic is fully source- and binary-compatible (native code only) with Microsoft Visual C++ (MSVC). You can debug binaries built with the Intel® C++ Compiler Classic from within the Microsoft Visual Studio environment.

The compiler supports security checks with the /GS option. You can control this option in the Microsoft Visual Studio IDE by using **C/C++** > **Code Generation** > **Buffer Security Check**.

The compiler also includes support for safe exception handling features with the /Qsafeseh option for 32-bit binaries. This option is on by default. You can control this option in the Microsoft Visual Studio IDE by using **C/C++** > **Command Line** > **Additional options**.

> **Important**
> The compiler is a *hosted* compiler, not a *standalone* compiler. The compiler requires that standard development tools for the host system (linker, librarian, and so forth), and standard libraries and headers, are installed and available in your Path, Library Path, and Include environment variables. The host compiler provides access to I/O facilities through, for example, `<stdio.h>` and the C runtime library, as well as providing the implementation for the C++ standard template (for example, `<vector>`). When you build your application with the compiler, the `stdio.h` file is found in the host compiler's library. Likewise when you link your application, the link step uses the host OS linker to bind the application, and the host C runtime library provides the implementation for the runtime support routines.
>
> On Windows, the standard compiler is Microsoft Visual C++. On Linux, the standard compiler is GCC. The standard compiler must be installed and available in your environment before you run the compiler.

Microsoft Visual Studio Integration

The compiler is compatible with Microsoft Visual Studio 2017, 2019, and 2022 projects.

> **NOTE** Support for Microsoft Visual Studio 2017 is deprecated as of the Intel® oneAPI 2022.1 release, and will be removed in a future release.

Unsupported Features

Unsupported project types:

- .NET-based CLR C++ project types are not supported by the Intel® C++ Compiler Classic. The specific project types will vary depending on your version of Visual Studio, for example:
  - CLR Class Library
  - CLR Console App
  - CLR Empty Project

Unsupported major features:

- COM Attributes
- C++ Accelerated Massive Parallelism (C++ AMP)
- Managed extensions for C++ (new pragmas, keywords, and command-line options)
- Event handling (new keywords)
- Select keywords:
  - `__abstract`

- `__box`
- `__delegate`
- `__gc`
- `__identifier`
- `__nogc`
- `__pin`
- `__property`
- `__sealed`
- `__try_cast`
- `__w64`

Unsupported preprocessor features:

- `#import` directive changes for attributed code
- `#using` directive
- `managed`, `unmanaged` pragmas
- `_MANAGED` macro
- `runtime_checks` pragma

Mixing Managed and Unmanaged Code

If you use the managed extensions to the C++ language in Microsoft Visual Studio .NET, you can use the compiler for your non-managed code for better application performance. Make sure managed keywords do not appear in your non-managed code.

For information on how to mix managed and unmanaged code, refer to the article, An Overview of Managed/Unmanaged Code Interoperability, on the Microsoft Web site.

Precompiled Header Support

There are some differences in how precompiled header (PCH) files are supported between the Intel® C++ Compiler Classic and the Microsoft Visual C++ Compiler:

- The PCH information generated by the Intel® C++ Compiler Classic is not compatible with the PCH information generated by the Microsoft Visual Studio Compiler.
- The Intel® C++ Compiler Classic does not support PCH generation and use in the same translation unit.
- The Intel® C++ Compiler does not generate PCH information beyond a point where a declaration is seen in the primary translation unit. When the `/Yu` option is specified, the Microsoft Visual C++ compiler ignores all text, including declarations preceding the `#include` statement of the specified file.
- The Microsoft Visual C++ Compiler will not emit an error if a function or variable definition occurs in a PCH file, which is included in two different source files and is not referenced. The Intel® C++ Compiler will always give a multiple definition link error under these circumstances.

Compilation and Execution Differences

While the Intel® C++ Compiler Classic is compatible with the Microsoft Visual C++ Compiler, some differences can prevent successful compilation. There can also be some incompatible generated-code behavior of some source files with the Intel® C++ Compiler Classic. In most cases, a modification of the user source file enables successful compilation with both the Intel® C++ Compiler Classic and the Microsoft Visual C++ Compiler. The differences between the compilers are:

- **Evaluation of Left Shift Operations**

  The Intel® C++ Compiler differs from the Microsoft Visual C++ Compiler in the evaluation of left shift operations where the right operand, or shift count, is equal to or greater than the size of the left operand expressed in bits. The ANSI C standard states that the behavior of such left-shift operations is undefined, meaning a program should not expect a certain behavior from these operations. This difference is only evident when both operands of the shift operation are constants. The following example illustrates this difference between the Intel® C++ Compiler and the Microsoft Visual C++ Compiler:

```
int x;
int y = 1; //set y=1
void func() {
  x = 1 << 32;
  // Intel C++ Compiler generates code to set x=1
  // Visual C++ Compiler generates code to set x=0

  y = y << 32;
  // Intel C++ Compiler generates code to set y=1
  // Visual C++ Compiler generates code to set y=1
}
```

- **Inline Assembly Target Labels (IA-32 Architecture Only)**

  For compilations targeted for IA-32 architecture, inline assembly target labels of `goto` statements are case sensitive. The Microsoft Visual C++ compiler treats these labels in a case insensitive manner. For example, the Intel® C++ Compiler Classic issues an error when compiling the following code:

```
int func(int x) {
   goto LAB2;
     // error: label "LAB2" was referenced but not defined
   __asm lab2: mov x, 1
   return x;
}
```

  However, the Microsoft Visual C++ Compiler accepts the preceding code. As a work-around for the Intel® C++ Compiler Classic, when a `goto` statement refers to a label defined in inline assembly, you must match the label reference with the label definition in both name and case.

- **Inlining Functions Marked for dllimport**

  The Intel® C++ Compiler Classic will attempt to inline any functions that are marked dllimport but Microsoft will not. Therefore, any calls or variables used inside a dllimport routine need to be available at link time or the result will be an unresolved symbol.

  The following example contains two files: `header.h` and `bug.cpp`.

  header.h:

```
#ifndef _HEADER_H
#define _HEADER_H
namespace Foo_NS {

        class Foo2 {
        public:
                Foo2(){};
                ~Foo2();
                static int test(int m_i);
        };
}
#endif
```

  bug.cpp:

```
#include "header.h"
struct Foo2 {
  static void test();
};
```

```
struct __declspec(dllimport) Foo
{
   void getI() { Foo2::test(); };
};

struct C  {
  virtual void test();
};

void C::test() { Foo p;  p->getI(); }

int main() {
   return 0;
}
```

Declaration in Scope of Function Defined in a Namespace

In accordance with the C++ language specification, if a function declaration is encountered within a function definition, the function referenced is taken to be another member of the namespace of the containing function. This is regardless of whether the containing function definition is lexically within a namespace definition. The Microsoft Visual C++ compiler takes the referenced function to be a global function (not in any namespace).

Functions declared in global or namespace scopes are interpreted the same way by both the Intel® C++ Compiler and the Microsoft Visual C++ compiler.

Enum Bit-Field Signedness

The Intel® C++ Compiler Classic and Microsoft Visual C++ differ in how they attribute signedness to bit fields declared with an `enum` type. Microsoft Visual C++ always considers `enum` bit fields to be signed, even if not all values of the `enum` type can be represented by the bit field.

The Intel® C++ Compiler Classic considers an `enum` bit field to be unsigned, unless the `enum` type has at least one `enum` constant with a negative value. In any case, the Intel® C++ Compiler Classic produces a warning if the bit field is declared with too few bits to represent all the values of the `enum` type.

Port from Microsoft Visual C++ to the Intel® C++ Compiler Classic*

This section describes a basic approach to porting applications from Microsoft Visual C++* for Windows* to the Intel® C++ Compiler Classic for Windows.

If you build your applications from the Windows command line, you can port applications from Microsoft Visual C++ to the Intel® C++ Compiler Classic by modifying your makefile to invoke the Intel® C++ Compiler Classic instead of Microsoft Visual C++.

The Intel® C++ Compiler Classic integration with Microsoft Visual Studio provides a conversion path to the Intel® C++ Compiler Classic that allows you to build your Visual C++ projects with the Intel® C++ Compiler Classic. This version of the Intel® C++ Compiler Classic supports:

- Microsoft Visual Studio 2022

- Microsoft Visual Studio 2019
- Microsoft Visual Studio 2017

> **NOTE** Support for Microsoft Visual Studio 2017 is deprecated as of the Intel® oneAPI 2022.1 release, and will be removed in a future release.

See the appropriate section in this documentation for details on using the Intel® C++ Compiler Classic with Microsoft Visual Studio.

The Intel® C++ Compiler Classic also supports many of the same compiler options, macros, and environment variables you already use in your Microsoft work.

One challenge in porting applications from one compiler to another is making sure there is support for the compiler options you use to build your application. The *Compiler Options* reference lists compiler options that are supported by both the Intel® C++ Compiler Classic and Microsoft C++.

See Also

Other Considerations

Modify Your Makefile

Modify Your makefile

If you use makefiles to build your Microsoft* application, you need to change the value for the compiler variable to use the Intel® C++ Compiler Classic. You may also want to review the options specified by `CPPFLAGS`. For example, a sample Microsoft makefile:

```
# name of the program
  PROGRAM = area.exe

# names of source files
  CPPSOURCES = area_main.cpp area_functions.cpp

# names of object files
  CPPOBJECTS = area_main.obj area_functions.obj

# Microsoft(R) compiler options
  CPPFLAGS = /RTC1 /EHsc

# Use Microsoft C++(R)
  CPP = cl

# link objects
  $(PROGRAM): $(CPPOBJECTS)
     link.exe /out:$@ $(CPPOBJECTS)

# build objects
  area_main.obj: area_main.cpp area_headers.h
  area_functions.obj: area_functions.cpp area_headers.h

# clean
  clean:  del  $(CPPOBJECTS) $(PROGRAM)
```

Modified makefile for the Intel® C++ Compiler Classic

Before you can run `nmake` with the Intel® C++ Compiler Classic, you need to set the proper environment. In this example, only the name of the compiler changed to use icc:

```
# name of the program
  PROGRAM = area.exe

# names of source files
  CPPSOURCES = area_main.cpp area_functions.cpp

# names of object files
  CPPOBJECTS = area_main.obj area_functions.obj

# Intel(R) C/C++ Compiler options
  CPPFLAGS = /RTC1 /EHsc

# Use the Intel C/C++ Compiler
  CPP = icc

# link objects
  $(PROGRAM): $(CPPOBJECTS)
     link.exe /out:$@ $(CPPOBJECTS)

# build objects
  area_main.obj: area_main.cpp area_headers.h
  area_functions.obj: area_functions.cpp area_headers.h

# clean
  clean:  del  $(CPPOBJECTS) $(PROGRAM)
```

With the modified makefile, the output of `nmake` is similar to the following:

```
Microsoft (R) Program Maintenance Utility Version 8.00.50727.42
Copyright (C) Microsoft Corporation. All rights reserved.

        icl /RTC1 /EHsc  /c area_main.cpp area_functions.cpp

Intel(R) Compiler for applications running on IA-32 or IA-64
Copyright (C) 1985-2006 Intel Corporation. All rights reserved.

area_main.cpp
area_functions.cpp
        link.exe /out:area.exe area_main.obj area_functions.obj

Microsoft (R) Incremental Linker Version 8.00.50727.42
Copyright (C) Microsoft Corporation. All rights reserved.
```

Use IPO in makefiles

By default, IPO generates dummy object files containing interprocedural information used by the compiler. To link or create static libraries with these object files requires specific Intel-provided tools. To use them in your makefile, replace references to `link` with `xilink` and references to `lib` with `xilib`. For example:

```
 # name of the program
  PROGRAM = area.exe

# names of source files
  CPPSOURCES = area_main.cpp area_functions.cpp
```

```
# names of object files
  CPPOBJECTS = area_main.obj area_functions.obj

# Intel C/C++ Compiler options
  CPPFLAGS = /RTC1 /EHsc /Qipo

# Use the Intel C/C++ Compiler
  CPP = icc

# link objects
  $(PROGRAM): $(CPPOBJECTS)
     xilink.exe /out:$@ $(CPPOBJECTS)

# build objects
  area_main.obj: area_main.cpp area_headers.h
  area_functions.obj: area_functions.cpp area_headers.h

# clean
  clean:  del  $(CPPOBJECTS) $(PROGRAM)
```

Other Considerations

There are some notable differences between the Intel® C++ Compiler Classic and the Microsoft* Compiler. Consider the following as you begin compiling your code with the Intel® C++ Compiler Classic.

Set the Environment

The compiler installation provides a batch file, `setvars.bat`, that sets the proper environment for the Intel® C++ Compiler Classic. For information on running `setvars.bat`, see Specifying the Location of Compiler Components.

Use Optimization

The Intel® C++ Compiler Classic is an optimizing compiler that begins with the assumption that you want improved performance from your application when it is executed on Intel® architecture. Consequently, certain optimizations, such as option `O2`, are part of the default invocation of the compiler. By default, Microsoft turns off optimization, which is the equivalent of compiling with options `Od` or `O0`. Other forms of the `O`[*n*] option compare as follows:

Option	Intel® C++ Compiler Classic	Microsoft Compiler
`/Od`	Turns off all optimization. Same as `O0`.	Default. Turns off all optimization.
`/O1`	Decreases code size with some increase in speed.	Optimizes code for minimum size.
`/O2`	Default. Favors speed optimization with some increase in code size. Intrinsics, loop unrolling, and inlining are performed.	Optimizes code for maximum speed.
`/O3`	Enables `-O2` optimizations plus more aggressive optimizations, such as prefetching, scalar replacement, and loop and memory access transformations.	Not supported.

Target Specific Intel® Processors

While many of the same options that target specific processors are supported with both compilers, the Intel® C++ Compiler includes options that utilize processor-specific instructions to target the latest Intel® architecture processors. Consider using the Intel® C++ Compiler `[Q]x` , `/arch` , or `[Q]ax` options for applications that run on IA-32 architecture or Intel® 64 architecture. Refer to the descriptions of these compiler options for more specific information.

Modify Your Configuration

The Intel® C++ Compiler Classic lets you maintain configuration and response files that are part of compilation. Options stored in the configuration file apply to every compilation, while options stored in response files apply only where they are added on the command line. If you have several options in your makefile that apply to every build, you may find it easier to move these options to the configuration file (`..\bin\icc.cfg`).

In a multi-user, networked environment, options listed in the `icc.cfg` file are generally intended for everyone who uses the compiler. If you need a separate configuration, you can use the `ICCCFG` environment variable to specify the name and location of your own `.cfg` file, such as `\my_code\my_config.cfg`. Anytime you instruct the compiler to use a different configuration file, the `icc.cfg` system configuration file is ignored.

Use the Intel Libraries

The Intel® C++ Compiler Classic supplies additional libraries that contain optimized implementations of many commonly used functions. Some of these functions are implemented using CPU dispatch. This means that different code may be executed when run on different processors.

Supplied libraries include the Intel® C++ Compiler Classic (*libm*), the Short Vector Math Library (*svml_disp*), *libirc*, as well as others. These libraries are linked in by default when the compiler sees that references to them have been generated. Some library functions, such as `sin` or `memset`, may not require a call to the library, since the compiler may inline the code for the function.

Intel® C++ Compiler Classic Math Library (*libm*)

With the Intel® C++ Compiler Classic, the math library, *libm*, is linked by default when calling math functions that require the library. Some functions, such as `sin`, may not require a call to the library, since the compiler already knows how to compute the `sin` function. The math library also includes some functions not found in the standard math library.

> **NOTE**
> You cannot make calls to the math library with the Microsoft Compiler.

Many routines in the *libimf* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Short Vector Math Library (*svml_disp*)

When vectorization is in progress, the compiler may translate some calls to the *libm* math library functions into calls to *svml_disp* functions. These functions implement the same basic operations as the math library, but operate on short vectors of operands. This results in greater efficiency. In some cases, the *svml_disp* functions are slightly less precise than the equivalent *libm* functions.

Many routines in the Short Vector Math Library (SVML) are more optimized for Intel® microprocessors than for non-Intel microprocessors.

libirc

libirc contains optimized implementations of some commonly used string and memory functions. For example, it contains functions that are optimized versions of `memcpy` and `memset`. The compiler will automatically generate calls to these functions when it sees calls to `memcpy` and `memset`. The compiler may also transform loops that are equivalent to `memcpy` or `memset` into calls to these functions.

Many routines in the *libirc* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Port from GCC* to the Intel® C++ Compiler Classic

This section describes a basic approach to porting applications from the (GNU Compiler Collection*) GCC C/C++ compilers to the Intel® C++ Compiler Classic. These compilers correspond to each other as follows:

Language	Intel® Compiler	GCC Compiler
C	`icc`	`gcc`
C++	`icpc`	`g++`

NOTE Unless otherwise indicated, the term "`gcc`" refers to both GCC and G++* compilers from the GCC.

Advantages to Using the Intel® C++ Compiler Classic

In many cases, porting applications from `gcc` to the Intel® C++ Compiler Classic can be as easy as modifying your makefile to invoke the Intel® C++ Compiler Classic (`icc`) instead of `gcc`. Using the Intel® C++ Compiler Classic typically improves the performance of your application, especially for those that run on Intel processors. In many cases, your application's performance may also show improvement when running on non-Intel processors. When you compile your application with the Intel® C++ Compiler Classic, you have access to:

- Compiler options that optimize your code for the latest Intel® architecture processors.
- Advanced profiling tools (PGO) similar to the GNU profiler `gprof`.
- High-level optimizations (HLO).
- Interprocedural optimization (IPO).
- Intel intrinsic functions that the compiler uses to inline instructions, including various versions of Intel® Streaming SIMD Extensions and Intel® Advanced Vector Extensions.

- Highly-optimized Intel® C++ Compiler Classic Math Library for improved accuracy.

Because the Intel® C++ Compiler Classic is compatible and interoperable with `gcc`, porting your `gcc` application to the Intel® C++ Compiler Classic includes the benefits of binary compatibility. As a result, you should not have to re-build libraries from your `gcc` applications. The Intel® C++ Compiler Classic also supports many of the same compiler options, macros, and environment variables you already use in your `gcc` work.

Equivalent Macros

The Intel® C++ Compiler Classic is compatible with the predefined GNU* macros.

See http://gcc.gnu.org for a list of compatible predefined macros.

Modify Your makefile
Supported Environment Variables
Additional Predefined Macros

Modify Your makefile

If you use makefiles to build your GCC* application, you need to change the value for the GCC compiler variable to use the Intel® C++ Compiler Classic. You may also want to review the options specified by `CFLAGS`. For example, a sample GCC makefile:

```
# Use gcc compiler
  CC = gcc

# Compile-time flags
  CFLAGS = -O2 -std=c99
all: area_app

area_app: area_main.o area_functions.o
    $(CC) area_main.o area_functions.o -o area

area_main.o: area_main.c
    $(CC) -c $(CFLAGS) area_main.c

area_functions.o: area_functions.c
    $(CC) -c -fno-asm $(CFLAGS) area_functions.c

clean: rm -rf *o area
```

Modified makefile for the Intel® C++ Compiler Classic

In this example, the name of the compiler is changed to use icc

```
# Use Intel C/C++ Compiler
  CC = icc

# Compile-time flags
```

```
  CFLAGS = -std=c99
all: area_app

area_app: area_main.o area_functions.o
    $(CC) area_main.o area_functions.o -o area

area_main.o: area_main.c
    $(CC) -c $(CFLAGS) area_main.c

area_functions.o: area_functions.c
    $(CC) -c -fno-asm $(CFLAGS) area_functions.c

clean: rm -rf *o area
```

If your GCC code includes features that are not supported with the Intel® C++ Compiler Classic (compiler options, language extensions, macros, pragmas, and so on), you can compile those sources separately with GCC if necessary.

In the above makefile, `area_functions.c` is an example of a source file that includes features unique to GCC. Because the Intel® C++ Compiler Classic uses the `O2` option by default and GCC uses option `O0` as the default, we instruct GCC to compile at option `O2`. We also include the `-fno-asm` switch from the original makefile because this switch is not supported with the Intel® C++ Compiler Classic. The following sample makefile is modified for using the Intel® C++ Compiler Classic and GCC together:

```
# Use Intel C/C++ Compiler
  CC = icc
# Use gcc for files that cannot be compiled by icc
  GCC = gcc
# Compile-time flags
  CFLAGS = -std=c99
all: area_app

area_app: area_main.o area_functions.o
    $(CC) area_main.o area_functions.o -o area

area_main.o: area_main.c
    $(CC) -c $(CFLAGS) area_main.c

area_functions.o: area_functions.c
    $(GCC) -c -O2 -fno-asm $(CFLAGS) area_functions.c

clean: rm -rf *o area
```

Output of `make` using a modified makefile:

```
icc -c -std=c99 area_main.c
gcc -c -O2 -fno-asm -std=c99 area_functions.c
icc area_main.o area_functions.o -o area
```

Use IPO in Makefiles

By default, IPO generates "dummy" object files containing Interprocedural information used by the compiler. To link or create static libraries with these object files requires special Intel-provided tools. To use them in your makefile, simply replace references to "ld" with "xild" and references to "ar" with "xiar", or use `icc` to link as shown in the example:

```
# Use Intel C/C++ Compiler
  CC = icc
# Compile-time flags
  CFLAGS = -std=c99 -ipo
```

```
all: area_app

area_app: area_main.o area_functions.o
    $(CC) area_main.o area_functions.o -o area

area_main.o: area_main.c
    $(CC) -c $(CFLAGS) area_main.c

area_functions.o: area_functions.c
    $(CC) -c $(CFLAGS) area_functions.c

clean: rm -rf *o area
```

Other Considerations

There are some notable differences between the Intel® C++ Compiler Classic and GCC*. Consider the following as you begin compiling your source code with the Intel® C++ Compiler Classic.

Set the Environment

The Intel® C++ Compiler Classic relies on environment variables for the location of compiler binaries, libraries, man pages, and license files. In some cases these are different from the environment variables that GCC uses. Another difference is that these variables are not set by default after installing the Intel® C++ Compiler Classic. The following environment variables need to be set prior to running the Intel® C++ Compiler Classic:

- PATH: Add the location of the compiler binaries to PATH.
- LD_LIBRARY_PATH: Sets the location where the generated executable picks up the runtime libraries (*.so files).
- MANPATH – add the location of the compiler man pages (`icc or icpc`) to MANPATH.
- INTEL_LICENSE_FILE – sets the location of the Intel® C++ Compiler license file.

To set these environment variables, run the `compilervars.sh` script.

NOTE
Setting these environment variables with `compilervars.sh` does not impose a conflict with GCC. You should be able to use both compilers in the same shell.

Use Optimization

The Intel® C++ Compiler Classic is an optimizing compiler that begins with the assumption that you want improved performance from your application when it is executed on Intel® architecture. Consequently, certain optimizations, such as option `O2`, are part of the default invocation of the Intel® C++ Compiler Classic. Optimization is turned off in GCC by default, the equivalent of compiling with option `O0`. Other forms of the `O`<*n*> option compare as follows:

Option	Intel® C++ Compiler Classic	GCC
`-O0`	Turns off optimization.	Default. Turns off optimization.
`-O1`	Decreases code size with some increase in speed.	Decreases code size with some increase in speed.

Option	Intel® C++ Compiler Classic	GCC
`-O2`	**Default.** Favors speed optimization with some increase in code size. Same as option `O`. Intrinsics, loop unrolling, and inlining are performed.	Optimizes for speed as long as there is not an increase in code size. Loop unrolling and function inlining, for example, are not performed.
`-O3`	Enables option `O2` optimizations plus more aggressive optimizations, such as prefetching, scalar replacement, and loop and memory access transformations.	Optimizes for speed while generating larger code size. Includes option `O2` optimizations plus loop unrolling and inlining. Similar to option `O2 -ip` on the Intel® C++ Compiler.

Target Intel® Processors

While many of the same options that target specific processors are supported with both compilers, Intel includes options that utilize processor-specific instruction scheduling to target the latest Intel® processors. If you compile your GCC application with the `march` or `mtune` option, consider using the Intel® C++ Compiler options `x` or `ax` options for applications that run on IA-32 architecture or Intel® 64 architecture.

Modify Your Configuration

The Intel® C++ Compiler Classic lets you maintain configuration and response files that are part of compilation. Options stored in the configuration file apply to every compilation, while options stored in response files apply only where they are added on the command line. If you have several options in your makefile that apply to every build, you may find it easier to move these options to the configuration file (`icc.cfg or icpc.cfg`).

In a multi-user, networked environment, options listed in the `icc.cfg or icpc.cfg` files are generally intended for everyone who uses the compiler. If you need a separate configuration, you can use the `ICCCFG or ICPCCFG`environment variable to specify the name and location of your own `.cfg` file, such as `/my_code/my_config.cfg`. Anytime you instruct the compiler to use a different configuration file, the system configuration files (`icc.cfg or icpc.cfg`) are ignored.

Use the Intel Libraries

The Intel® C++ Compiler Classic supplies additional libraries that contain optimized implementations of many commonly used functions. Some of these functions are implemented using CPU dispatch. This means that different code may be executed when run on different processors.

Supplied libraries include the Intel® C++ Compiler Classic Math Library (*libimf*), the Short Vector Math Library (*libsvml*), *libirc*, as well as others. These libraries are linked in by default. Some library functions, such as `sin` or `memset`, may not require a call to the library, since the compiler may inline the code for the function.

NOTE The Intel Compiler Math Libraries contain performance-optimized implementations for various Intel platforms. By default, the best implementation for the underlying hardware is selected at runtime. The library dispatch of multi-threaded code may lead to apparent data races, which may be detected by certain software analysis tools. However, as long as the threads are running on cores with the same CPUID, these data races are harmless and are not a cause for concern.

Intel® C++ Compiler Classic Math Library (*libimf*)

With the Intel® Compiler, the math library, *libimf*, is linked by default. Some functions, such as sin, may not require a call to the library, since the compiler already knows how to compute the `sin` function. The math library also includes some functions not found in the standard math library.

NOTE
You cannot make calls to the math library with GCC.

Many routines in the *libimf* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Short Vector Math Library (*libsvml*)

When vectorization is being done, the compiler may translate some calls to the *libimf* math library functions into calls to *libsvml* functions. These functions implement the same basic operations as the math library, but operate on short vectors of operands. This results in greater efficiency. In some cases, the *libsvml* functions are slightly less precise than the equivalent *libimf* functions.

Many routines in the *libimf* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

libirc

libirc contains optimized implementations of some commonly used string and memory functions. For example, it contains functions that are optimized versions of `memcpy` and `memset`. The compiler will automatically generate calls to these functions when it sees calls to `memcpy` and `memset`. The compiler may also transform loops that are equivalent to `memcpy` or `memset` into calls to these functions.

Many routines in the *libirc* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
